

Debugging Tools for Windows (WinDbg, KD, CDB, NTSD)

March 2017

Start here for an overview of Debugging Tools for Windows. This tool set includes WinDbg and other debuggers.

3 ways to get Debugging Tools for Windows

- As part of the WDK

Install Microsoft Visual Studio and then install the Windows Driver Kit (WDK). Debugging Tools for Windows is included in the WDK. You can [get the integrated environment here](#).

- As part of the Windows SDK

Install the Windows Software Development Kit (SDK). Debugging Tools for Windows is included in the Windows SDK. You can [get the Windows SDK here](#).

- As a standalone tool set

If you want to download only Debugging Tools for Windows, [install the Windows SDK](#), and, during the installation, select the **Debugging Tools for Windows** box and clear all the other boxes.

Getting Started with Windows Debugging

To get started with Windows debugging, see [Getting Started with Windows Debugging](#).

To get started with debugging kernel mode drivers, see [Debug Universal Drivers - Step by Step Lab \(Echo Kernel-Mode\)](#). This is a step by step lab that shows how to use WinDbg to debug the sample KMDF echo driver.

Debugging environments

After you install Visual Studio and the WDK, you'll have six available [debugging environments](#). All of these debugging environments provide user interfaces for the same underlying debugging engine, which is implemented in dbgeng.dll. This debugging engine is called the *Windows debugger*, and the six debugging environments are collectively called the *Windows debuggers*.

Note Visual Studio includes its own debugging environment and debugging engine, which together are called the *Visual Studio debugger*. For information on debugging in Visual Studio, see [Visual Studio debugger](#). If you are looking to debug managed code such as C#, using the Visual Studio is often easiest way to get started.

Windows debuggers

The Windows debuggers can run on x86-based, x64-based, or ARM-based processors, and they can debug code that's running on x86-based, x64-based, or ARM-based processors. Sometimes the debugger and the code being debugged run on the same computer, but other times the debugger and the code being debugged run on separate computers. In either case, the computer that's running the debugger is called the *host computer*, and the computer that is being debugged is called the *target computer*. The Windows debuggers support the following versions of Windows for both the host and target computers.

- Windows 10 and Windows Server 2016
- Windows 8.1 and Windows Server 2012 R2
- Windows 8 and Windows Server 2012
- Windows 7 and Windows Server 2008 R2

Symbols and Symbol Files

Symbol files hold a variety of data which are not actually needed when running the binaries, but are very useful when debugging code. For more information about creating and using symbol files, see [Symbols for Windows debugging \(WinDbg, KD, CDB, NTSD\)](#).

Blue Screens and crash dump files

If Windows stops working and displays a blue screen, the computer has shut down abruptly to protect itself from data loss and displays a bug check code. For more information, see [Bug Checks \(Blue Screens\)](#). You analyze crash dump files that are created when Windows shuts down by using WinDbg and other Windows debuggers. For more information, see [Crash dump analysis using the Windows debuggers \(WinDbg\)](#).

Tools and utilities

In addition to the debuggers, Debugging Tools for Windows includes a set of tools that are useful for debugging. For a full list of the tools, see [Tools Included in Debugging Tools for Windows](#).

Additional documentation

For additional information related to Debugging Tools for Windows, see [Debugging Resources](#). For information on what's new in Windows 10, see [Debugging Tools for Windows: New for Windows 10](#).

Getting Started with Windows Debugging

This section covers how to get started with Windows Debugging. If your goal is to use the debugger to analyze a crash dump, see [Crash dump analysis using the Windows debuggers \(WinDbg\)](#).

To get started with Windows Debugging, complete the following tasks.

1. Determine which devices will serve as the host system and the target system.

The debugger runs on the host system and the code that you want to debug runs on the target system.

Host <-----> Target

Because it is common to stop instruction execution on the processor during debugging, typically, two systems are used. In some situations, it is possible that the second system is a virtual system, for example, a virtual PC that is running on the same PC. However, if your code is communicating to low level hardware, using a virtual PC may not be the best approach. For more information, see [Setting Up Network Debugging of a Virtual Machine Host](#).

2. Determine if you will be doing kernel or user mode debugging.

Kernel mode - Kernel mode is the processor access mode in which the operating system and privileged programs run. Kernel mode code has permission to access any part of the system, and is not restricted like user mode code. It can gain access to any part of any other process running in either user mode or kernel mode. Much of the core OS functionality and many hardware device drivers run in kernel mode.

User mode - Applications and subsystems run on the computer in user mode. Processes that run in user mode do so within their own virtual address spaces. They are restricted from gaining direct access to many parts of the system, including system hardware, memory that was not allocated for their use, and other portions of the system that might compromise system integrity. Because processes that run in user mode are effectively isolated from the system and other user mode processes, they cannot interfere with these resources.

If your goal is to debug a driver, determine if the driver is a kernel mode driver (typically described as a WDM or KMDF driver) or a user mode driver (UMDF).

For some issues, it can be difficult to determine which mode the code is executing in. In that case, you may need to pick one mode and look to see what information is available in that mode. Some issues require using the debugger in both user and kernel mode.

Depending on what mode you decide to debug in, you will need to configure and use the debuggers in different ways. Some debug commands operate the same, and some commands operate differently in different modes.

For information about using the debugger in kernel mode, see [Getting Started with WinDbg \(Kernel-Mode\)](#) and [Debug Universal Drivers - Step by Step Lab \(Echo Kernel-Mode\)](#). For information about using the debugger in user mode, see [Getting Started with WinDbg \(User-Mode\)](#).

3. Chose your debugger environment.

WinDbg works well in most situations, but there are times when you may want to use another debugger such as console debuggers for automation or even Visual Studio. For more information, see [Debugging Environments](#).

4. Determine how you will connect the target and host system.

Typically, an Ethernet network connection is used to connect the target and host system. If you are doing early bring up work, or don't have an Ethernet connection on the device, other network connection options are available. For more information, see these topics:

- [Setting Up Kernel-Mode Debugging Manually](#)
- [Setting Up Kernel-Mode Debugging over a Network Cable Manually](#)
- [Setting Up Kernel-Mode Debugging using Serial over USB Manually](#)
- [Setting Up Network Debugging of a Virtual Machine Host](#)

If you wish to debug using Visual Studio, then refer to these topics.

- [Setting Up Kernel-Mode Debugging in Visual Studio](#)
- [Setting Up Kernel-Mode Debugging over a Network Cable in Visual Studio](#)
- [Setting Up Kernel-Mode Debugging using Serial over USB in Visual Studio](#)
- [Setting Up Kernel-Mode Debugging of a Virtual Machine in Visual Studio](#)

- [Setting Up User-Mode Debugging in Visual Studio](#)
5. Choose either the 32-bit or 64-bit debugging tools.

This choice is dependent on the version of Windows that is running on the target and host systems and whether you are debugging 32-bit or 64-bit code. For more information, see [Choosing the 32-Bit or 64-Bit Debugging Tools](#).

6. Configure symbols.

You must load the proper symbols to use all of the advanced functionality that WinDbg provides. If you do not have symbols properly configured, you will receive messages indicating that symbols are not available when you attempt to use functionality that is dependent on symbols. For more information, see [Symbols for Windows debugging \(WinDbg, KD, CDB, NTSD\)](#).

7. Configure source code.

If your goal is to debug your own source code, you will need to configure a path to your source code. For more information, see [Source Path](#).

8. Become familiar with debugger operation.

The [Debugger Operation](#) section of the documentation describes debugger operation for various tasks. For example, the [Loading Debugger Extension DLLs](#) topic explains how to load debugger extensions. To learn more about working with WinDbg, see [Debugging Using WinDbg](#).

9. Become familiar with debugging techniques.

[Standard Debugging Techniques](#) apply to most debugging scenarios, and examples include setting breakpoints, inspecting the call stack, and finding a memory leak. [Specialized Debugging Techniques](#) apply to particular technologies or types of code. Examples are Plug and Play debugging, Kernel Mode Driver Framework debugging, and RPC debugging.

10. Use the debugger reference commands.

Over time, you will use different debug commands as you work in the debugger. Use the [hh \(Open HTML Help File\)](#) command in the debugger to display help information about any debug command. For more information about the available commands, see [Debugger Reference](#).

11. Use debugging extensions for specific technologies.

There are a number of debugging extensions that provide parsing of domain specific data structures. For more information, see [Specialized Extensions](#).

This section contains the following topics.

- [Getting Started with WinDbg \(Kernel-Mode\)](#)
- [Getting Started with WinDbg \(User-Mode\)](#)
- [Choosing the 32-Bit or 64-Bit Debugging Tools](#)
- [Debugging Environments](#)
- [Setting Up Debugging \(Kernel-Mode and User-Mode\)](#)
- [Debug Universal Drivers - Step by Step Lab \(Echo Kernel-Mode\)](#)

Getting Started with WinDbg (User-Mode)

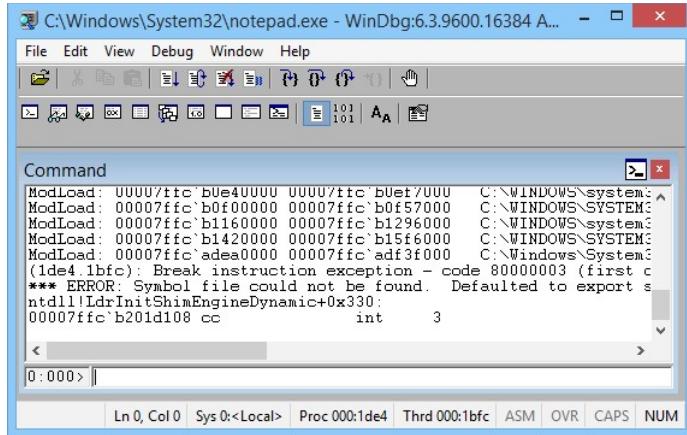

WinDbg is a kernel-mode and user-mode debugger that is included in Debugging Tools for Windows. Here we provide hands-on exercises that will help you get started using WinDbg as a user-mode debugger.

For information about how to get Debugging Tools for Windows, see [Debugging Tools for Windows \(WinDbg, KD, CDB, NTSD\)](#). After you have installed the debugging tools, locate the installation directories for 64-bit (x64) and 32-bit (x86) versions of the tools. For example:

- C:\Program Files (x86)\Windows Kits\8.1\Debuggers\x64
- C:\Program Files (x86)\Windows Kits\8.1\Debuggers\x86

Launch Notepad and attach WinDbg

1. Navigate to your installation directory, and open WinDbg.exe.
2. On the **Help** menu, choose **Contents**. This opens the debugger documentation CHM file. The debugger documentation is also available on line [here](#).
3. On the **File** menu, choose **Open Executable**. In the Open Executable dialog box, navigate to the folder that contains notepad.exe (for example, C:\Windows\System32). For **File name**, enter notepad.exe. Click **Open**.

- Near the bottom of the WinDbg window, in the command line, enter this command:

[.sympath srv*](#)

The output is similar to this:

```
Symbol search path is: srv*
Expanded Symbol search path is: cache*;SRV*https://msdl.microsoft.com/download/symbols
```

The symbol search path tells WinDbg where to look for symbol (PDB) files. The debugger needs symbol files to obtain information about code modules (function names, variable names, and the like).

Enter this command, which tells WinDbg to do its initial finding and loading of symbol files:

[.reload](#)

- To see the symbols for the Notepad.exe module, enter this command:

[x notepad!*](#)

Note If you don't see any output, enter [.reload](#) again.

To see symbols in the Notepad.exe module that contain main, enter this command:

[x notepad!*main*](#)

The output is similar to this:

```
000000d0`428ff7e8 00007ff6`3282122f notepad!WinMain
...
```

- To put a breakpoint at notepad!WinMain, enter this command:

[bu notepad!WinMain](#)

To verify that your breakpoint was set, enter this command:

[bl](#)

The output is similar to this:

```
0 e 00007ff6`32825f64 0001 (0001) 0:**** notepad!WinMain
```

- To start Notepad running, enter this command:

[g](#)

Notepad runs until it comes to the **WinMain** function, and then breaks in to the debugger.

To see a list of code modules that are loaded in the Notepad process, enter this command:

[lm](#)

The output is similar to this:

```
0:000> lm
start end module name
00007ffc`32820000 00007ff6`3285a000 notepad (pdb symbols) c:\...\notepad.pdb
00007ffc`ab7e0000 00007ffc`ab85b000 WINSPOOL (deferred)
00007ffc`aba10000 00007ffc`abc6a000 COMCTL32 (deferred)
00007ffc`adea0000 00007ffc`adf3f000 SHCORE (deferred)
00007ffc`af490000 00007ffc`af59f000 KERNELBASE (deferred)
00007ffc`af7d0000 00007ffc`af877000 msvcrt (deferred)
00007ffc`af880000 00007ffc`b0c96000 SHELL32 (deferred)
```

```
00007ffc`b0e40000 00007ffc`b0ef7000  OLEAUT32  (deferred)
00007ffc`b0f0000 00007ffc`b0f57000  sechost  (deferred)
00007ffc`b0f60000 00007ffc`b1005000  ADVAPI32  (deferred)
00007ffc`b1010000 00007ffc`b1155000  GDI32   (deferred)
00007ffc`b1160000 00007ffc`b1296000  RPCRT4   (deferred)
00007ffc`b12a0000 00007ffc`b1411000  USER32   (deferred)
00007ffc`b1420000 00007ffc`b15f6000  combase  (deferred)
00007ffc`b16c0000 00007ffc`b17f9000  MSCTF    (deferred)
00007ffc`b1800000 00007ffc`b189a000  COMDLG32 (deferred)
00007ffc`b18a0000 00007ffc`b18f1000  SHLWAPI  (deferred)
00007ffc`b1b60000 00007ffc`blcd8000  ole32   (deferred)
00007ffc`b1cf0000 00007ffc`ble2a000  KERNEL32 (pdb symbols)  C:\...\kernel32.pdb
00007ffc`b1eb0000 00007ffc`blee4000  IMM32   (deferred)
00007ffc`b1f50000 00007ffc`b20fa000  ntdll   (private pdb symbols)  C:\...\ntdll.pdb
```

To see a stack trace, enter this command:

k

The output is similar to this:

```
Breakpoint 0 hit
notepad!WinMain:
00007ff6`32825f64 488bc4      mov     rax, rsp
0:000> k
Child-SP      RetAddr      Call Site
00000048`4e0cf6a8 00007ff6`3282122f notepad!WinMain
00000048`4e0cf6b0 00007ffc`blfc1f6ad notepad!WinMainCRTStartup+0xa7
00000048`4e0cf770 00007ffc`blfc4629 KERNEL32!BaseThreadInitThunk+0xd
00000048`4e0cf7a0 00000000`00000000 ntdll!RtlUserThreadStart+0x1d ...
```

8. To start Notepad running again, enter this command:

g

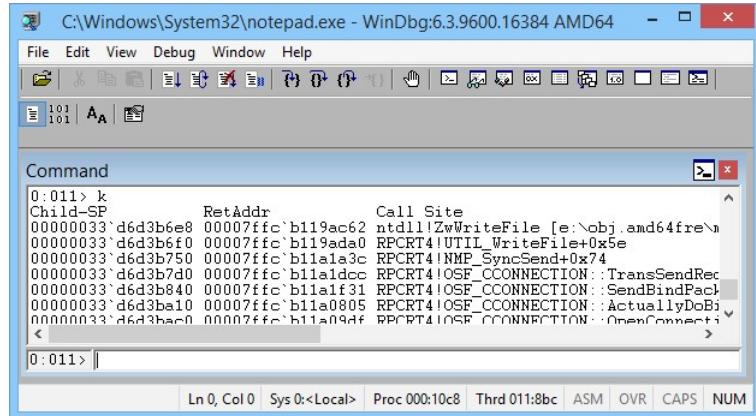

9. To break in to Notepad, choose **Break** from the **Debug** menu.

10. To set and verify a breakpoint at **ZwWriteFile**, enter these commands:

bu ntdll!ZwWriteFile

bl

11. Enter **g** to start Notepad running again. In the Notepad window, enter some text and choose **Save** from the **File** menu. The running code breaks in when it comes to **ZwCreateFile**. Enter **k** to see the stack trace.

In the WinDbg window, just to the left of the command line, notice the processor and thread numbers. In this example the current processor number is 0, and the current thread number is 11. So we are looking at the stack trace for thread 11 (which happens to be running on processor 0).

12. To see a list of all threads in the Notepad process, enter this command (the tilde):

~

The output is similar to this:

```
0:011> ~
0  Id: 10c8.128c Suspend: 1 Teb: 00007ff6`31cdd000 Unfrozen
1  Id: 10c8.1a10 Suspend: 1 Teb: 00007ff6`31cdb000 Unfrozen
2  Id: 10c8.1850 Suspend: 1 Teb: 00007ff6`31cd9000 Unfrozen
3  Id: 10c8.1774 Suspend: 1 Teb: 00007ff6`31cd7000 Unfrozen
4  Id: 10c8.1e80 Suspend: 1 Teb: 00007ff6`31cd5000 Unfrozen
5  Id: 10c8.10a0 Suspend: 1 Teb: 00007ff6`31cd3000 Unfrozen
6  Id: 10c8.13a4 Suspend: 1 Teb: 00007ff6`31bae000 Unfrozen
7  Id: 10c8.2b4 Suspend: 1 Teb: 00007ff6`31bac000 Unfrozen
8  Id: 10c8.1df0 Suspend: 1 Teb: 00007ff6`31baa000 Unfrozen
9  Id: 10c8.1664 Suspend: 1 Teb: 00007ff6`31ba8000 Unfrozen
10 Id: 10c8.15e4 Suspend: 1 Teb: 00007ff6`31ba6000 Unfrozen
. 11  Id: 10c8.8bc Suspend: 1 Teb: 00007ff6`31ba4000 Unfrozen
```

In this example, there are 12 threads with indexes 0 through 11.

13. To look at the stack trace for thread 0, enter these commands:

[~0s](#)

[k](#)

The output is similar to this:

```
0:011> ~0s
USER32!SystemParametersInfoW:
00007ffc`b12a4d20 48895c2408      mov     qword ptr [rsp+8], ...
0:000> k
Child-SP      RetAddr          Call Site
00000033`die9da48 00007ffc`adfb227d USER32!SystemParametersInfoW
(Inline Function) ----- uxtheme!IsHighContrastMode+0x1d
00000033`die9da50 00007ffc`adfb2f12 uxtheme!IsThemeActive+0x4d
...
00000033`die9f810 00007ffc`blcf16ad notepad!WinMainCRTStartup+0x1a7
00000033`die9f8d0 00007ffc`b1fc4629 KERNEL32!BaseThreadInitThunk+0xd
00000033`die9f900 00000000`00000000 ntdll!RtlUserThreadStart+0x1d
```

14. To quit debugging and detach from the Notepad process, enter this command:

[qd](#)

Launch your own application and attach WinDbg

Suppose you have written and built this small console application.

```
...
void MyFunction(long p1, long p2, long p3)
{
    long x = p1 + p2 + p3;
    long y = 0;
    y = x / p2;
}

void main ()
{
    long a = 2;
    long b = 0;
    MyFunction(a, b, 5);
}
```

For this exercise, we will assume that the built application (MyApp.exe) and the symbol file (MyApp.pdb) are in C:\MyApp\x64\Debug. We will also assume that the application source code is in C:\MyApp\MyApp.

1. Open WinDbg.
2. On the **File** menu, choose **Open Executable**. In the Open Executable dialog box, navigate to C:\MyApp\x64\Debug. For **File name**, enter MyApp.exe. Click **Open**.
3. Enter these commands:

[sympath srv*](#)

[.sympath+ C:\MyApp\x64\Debug](#)

[.srcpath C:\MyApp\MyApp](#)

Now WinDbg knows where to find symbols and source code for your application.

4. Enter these commands:

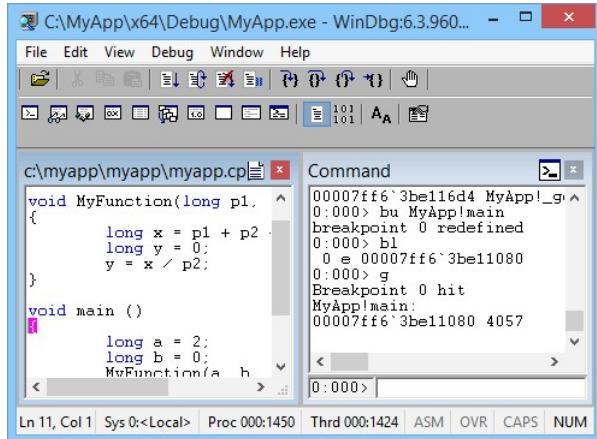

[.reload](#)

[bu MyApp!main](#)

[g](#)

Your application breaks in to the debugger when it comes to its **main** function.

WinDbg displays your source code and the Command window.

5. On the **Debug** menu, choose **Step Into** (or press **F11**). Continue stepping until you have stepped into **MyFunction**. When you step into the line $y = x / p2$, your application will crash and break in to the debugger. The output is similar to this:

```
(1450.1424): Integer divide-by-zero - code c0000094 (first chance)
First chance exceptions are reported before any exception handling.
This exception may be expected and handled.
MyApp!MyFunction+0x44:
00007ff6`3be11064 f77c2428      idiv    eax,dword ptr [rsp+28h] ss:00000063`2036f808=00000000
```

6. Enter this command:

!analyze -v

WinDbg displays an analysis of the problem (division by 0 in this case).

```
FAULTING_IP:
MyApp!MyFunction+44 [c:\myapp\myapp\myapp.cpp @ 7]
00007ff6`3be11064 f77c2428      idiv    eax,dword ptr [rsp+28h]

Getting Started with WinDbg (Kernel-Mode)

WinDbg is a kernel-mode and user-mode debugger that is included in Debugging Tools for Windows. Here we provide hands-on exercises that will help you get started using WinDbg as a kernel-mode debugger.

For information about how to get Debugging Tools for Windows, see [Debugging Tools for Windows \(WinDbg, KD, CDB, NTSD\)](#). After you have installed the debugging tools, locate the installation directories for 64-bit (x64) and 32-bit (x86) versions of the tools. For example:

- C:\Program Files (x86)\Windows Kits\8.1\Debuggers\x64
- C:\Program Files (x86)\Windows Kits\8.1\Debuggers\x86

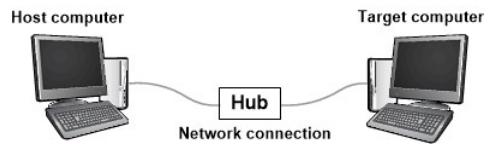

Set up a kernel-mode debugging

A kernel-mode debugging environment typically has two computers: the *host computer* and the *target computer*. The debugger runs on the host computer, and the code being debugged runs on the target computer. The host and target are connected by a debug cable.

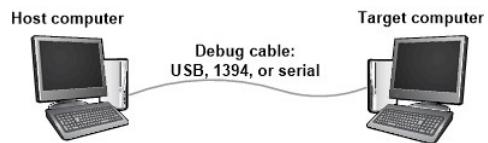

The Windows debuggers support these types of cables for debugging:

- Ethernet
- USB 2.0
- USB 3.0
- 1394
- Serial (also called null modem)

If your target computer is running Windows 8 or later, you can use any type of debug cable, including Ethernet. This diagram illustrates a host and target computer connected for debugging over Ethernet cable.

If your target computer is running a version of Windows earlier than Window 8, then you cannot use Ethernet for debugging; you must use USB, 1394, or serial. This diagram illustrates a host and target computer connected by a USB, 1394, or serial debug cable.

For details about how to set up the host and target computers, see [Setting Up Kernel-Mode Debugging Manually](#).

Establish a kernel-mode debugging session

After you have set up your host and target computer and connected them with a debug cable, you can establish a kernel-mode debugging session by following the instructions in the same topic that you used for getting set up. For example, if you decided to set up your host and target computers for debugging over Ethernet, you can find instructions for establishing a kernel-mode debugging session is this topic:

- [Setting Up Kernel-Mode Debugging over a Network Cable Manually](#)

Likewise, if you decided to set up your host and target computers for debugging over USB 2.0, you can find instructions for establishing a kernel-mode debugging session is this topic:

- [Setting Up Kernel-Mode Debugging over a USB 2.0 Cable Manually](#)

Get started using WinDbg

- On the host computer, open WinDbg and establish a kernel-mode debugging session with the target computer.
- In WinDbg, choose **Contents** from the **Help** menu. This opens the debugger documentation CHM file. The debugger documentation is also available on line [here](#).
- When you establish a kernel-mode debugging session, WinDbg might break in to the target computer automatically. If WinDbg has not already broken in, choose **Break** from the **Debug** menu.
- Near the bottom of the WinDbg window, in the command line, enter this command:

.sympath srv*

The output is similar to this:

```
Symbol search path is: srv*
Expanded Symbol search path is: cache*,SRV*https://msdl.microsoft.com/download/symbols
```

The symbol search path tells WinDbg where to look for symbol (PDB) files. The debugger needs symbol files to obtain information about code modules (function names, variable names, and the like).

Enter this command, which tells WinDbg to do its initial finding and loading of symbol files:

.reload

- To see a list of loaded modules, enter this command:

lm

The output is similar to this:

```
0:000>3: kd> lm
start end module name
fffff800`00000000 fffff800`00088000 CI (deferred)
...
fffff800`01143000 fffff800`01151000 BasicRender (deferred)
fffff800`01151000 fffff800`01163000 BasicDisplay (deferred)
...
fffff800`02a0e000 fffff800`03191000 nt (pdb symbols) C:\...\ntkrnlmp.pdb
fffff800`03191000 fffff800`03200000 hal (deferred)
...
```

- To start target computer running, enter this command:

g

- To break in again, choose **Break** from the **Debug** menu.
- Enter this command to examine the `_FILE_OBJECT` data type in the nt module:

dt nt! FILE OBJECT

The output is similar to this:

```
0:000>0: kd> dt nt!_FILE_OBJECT
+0x000 Type : Int2B
+0x002 Size : Int2B
+0x008 DeviceObject : Ptr64 _DEVICE_OBJECT
+0x010 Vpb : Ptr64 _VPB
...
+0x0c0 IrpList : _LIST_ENTRY
+0x0d0 FileObjectExtension : Ptr64 Void
```

- Enter this command to examine some of the symbols in the nt module:

x nt!*CreateProcess*

The output is similar to this:

```
0:000>0: kd> x nt!*CreateProcess*
fffff800`030821cc nt!ViCreateProcessCallbackInternal (<no parameter info>
...
fffff800`02e03904 nt!MmCreateProcessAddressSpace (<no parameter info>
fffff800`02cece00 nt!PspCreateProcessNotifyRoutine = <no type information>
...
```

- Enter this command to put a breakpoint at `MmCreateProcessAddressSpace`:

bu nt!MmCreateProcessAddressSpace

To verify that the breakpoint is set, enter this command:

bl

The output is similar to this:

```
0:000>0: kd> bu nt!MmCreateProcessAddressSpace
```

```
0: kd> bl
0 e fffff800`02e03904      0001 (0001) nt!MmCreateProcessAddressSpace
```

Enter **g** to let the target computer run.

- If the target computer doesn't break in to the debugger immediately, perform a few actions on the target computer (for example, open Notepad). The target computer will break in to the debugger when **MmCreateProcessAddressSpace** is called. To see the stack trace, enter these commands:

reload

k

The output is similar to this:

```
0:000>2: kd> k
Child-SP          RetAddr           Call Site
ffffd000`224b4c88  fffff800`02d96834  nt!MmCreateProcessAddressSpace
ffffd000`224b4c90  fffff800`02defe17  nt!PspAllocateProcess+0x5d4
ffffd000`224b5060  fffff800`02b698b3  nt!NtCreateUserProcess+0x55b
...
000000d7`4167fb0  00007ffd`14b064ad  KERNEL32!BaseThreadInitThunk+0xd
000000d7`4167fbe0  00000000`00000000  ntdll!RtlUserThreadStart+0x1d
```

- On the **View** menu, choose **Disassembly**.

On the **Debug** menu, choose **Step Over** (or press **F10**). Enter step commands a few more times as you watch the Disassembly window.

- Clear your breakpoint by entering this command:

bc *

Enter **g** to let the target computer run. Break in again by choosing **Break** from the **Debug** menu or pressing **CTRL-Break**.

- To see a list of all processes, enter this command:

!process 0 0

The output is similar to this:

```
0:000>0: kd> !process 0 0
**** NT ACTIVE PROCESS DUMP ****
PROCESS fffffe000002287c0
SessionId: none Cid: 0004 Peb: 00000000 ParentCid: 0000

```

19. To see a device node that has a service name of disk, enter this command:

!devnode 0 1 disk

```

0: kd> !devnode 0 1 disk
Dumping IopRootDeviceNode (= 0xfffffe000002dbd30)
DevNode 0xfffffe0000114fd30 for PDO 0xfffffe00001159610
    InstancePath is "IDE\DiskST3250820AS_____3.CHL____\5&14544e82&0&0.0.0"
    ServiceName is "disk"
    State = DeviceNodeStarted (0x308)
    Previous State = DeviceNodeEnumerateCompletion (0x30d)
...

```

20. The output of **!devnode 0 1** displays the address of the physical device object (PDO) for the node. Copy the address of a physical device object (PDO), and enter this command:

!devstack PdoAddress

For example: *PdoAddress!***devstack 0xfffffe00001159610**

```

0:000>0: kd> !devstack 0xfffffe00001159610
    !DevObj      !DrvObj      !DevExt      ObjectName
    fffffe00001d50040 \Driver\partmgr   fffffe00001d50190
    fffffe00001d51450 \Driver\disk     fffffe00001d515a0 DR0
    fffffe00001d5156e50 \Driver\ACPI    fffffe00001d8bf0

```

21. To get information about the driver disk.sys, enter this command:

!drvobj disk 2

```

0:000>0: kd> !drvobj disk 2
Driver object (fffffe00001d52680) is for:
    \Driver\disk

```

```

DriverEntry: fffff800006b1270 disk!GsDriverEntry
DriverStartIo: 00000000
DriverUnload: fffff800010b0b5c CLASSPNP!ClassUnload
AddDevice: fffff800010aa110 CLASSPNP!ClassAddDevice

Dispatch routines:
[00] IRP_MJ_CREATE fffff8000106d160CLASSPNP!ClassGlobalDispatch
[01] IRP_MJ_CREATE_NAMED_PIPE fffff80002b0ab24nt!IopInvalidDeviceRequest
[02] IRP_MJ_CLOSE fffff8000106d160CLASSPNP!ClassGlobalDispatch
[03] IRP_MJ_READ fffff8000106d160CLASSPNP!ClassGlobalDispatch
...
[1b] IRP_MJ_PNP fffff8000106d160CLASSPNP!ClassGlobalDispatch

```

22. The output of !drvobj displays addresses of dispatch routines: for example, CLASSPNP!ClassGlobalDispatch. To set and verify a breakpoint at ClassGlobalDispatch, enter these commands:

bu CLASSPNP!ClassGlobalDispatch

bl

Enter g to let the target computer run.

If the target computer doesn't break in to the debugger immediately, perform a few actions on the target computer (for example, open Notepad and save a file). The target computer will break in to the debugger when **ClassGlobalDispatch** is called. To see the stack trace, enter these commands:

.reload

k

The output is similar to this:

```

2: kd> k
Child-SP RetAddr Call Site
ffffd000`21d06cf8 fffff800`0056c14e CLASSPNP!ClassGlobalDispatch
ffffd000`21d06d00 fffff800`00f2c31d volmgr!VmReadWrite+0x13e

Choosing the 32-Bit or 64-Bit Debugging Tools

When you install Debugging Tools for Windows, you get both a 32-bit set of tools and a 64-bit set of tools. If you use the Microsoft Visual Studio [debugging environment](#), you don't have to be concerned about whether to use the 32- or 64-bit set because Visual Studio automatically chooses the correct debugging tools.

If you are using one of the other debugging environments (WinDbg, KD, CDB, or NTSD), you have to make the choice yourself. To determine which set of debugging tools to use, you need to know the type of processor that is running on your host computer and whether the host computer is running a 32- or 64-bit version of Windows.

The computer that runs the debugger is called the *host computer*, and the computer being debugged is called the *target computer*.

Host computer running a 32-bit version of Windows

If your host computer is running a 32-bit version of Windows, use the 32-bit debugging tools. (This situation applies to both x86-based and x64-based targets.)

x64-based host computer running a 64-bit version of Windows

If your host computer uses an x64-based processor and is running a 64-bit version of Windows, the following rules apply:

- If you are analyzing a dump file, you can use either the 32-bit debugging tools or the 64-bit debugging tools. (It is not important whether the dump file is a user-mode dump file or a kernel-mode dump file, and it is not important whether the dump file was made on an x86-based or an x64-based platform.)
- If you are performing live kernel-mode debugging, you can use either the 32-bit debugging tools or the x64 debugging tools. (This situation applies to both x86-based and x64-based targets.)
- If you are debugging live user-mode code that is running on the same computer as the debugger, use the 64-bit tools for debugging 64-bit code and 32-bit code running on WOW64. To set the debugger for 32-bit or 64-bit mode, use the [`.effmach`](#) command.
- If you are debugging live 32-bit user-mode code that is running on a separate target computer, use the 32-bit debugging tools.

Debugging Environments

Starting with Windows Driver Kit (WDK) 8.0, the driver development environment and the Windows debugger are integrated into Microsoft Visual Studio.

After you install Visual Studio and the WDK, you have six available debugging environments:

- Visual Studio with integrated Windows debugger
- Microsoft Windows Debugger (WinDbg)
- Microsoft Kernel Debugger (KD)
- NTKD
- Microsoft Console Debugger (CDB)
- Microsoft NT Symbolic Debugger (NTSD)

The following sections describe the debugging environments.

Visual Studio with integrated Windows debugger

Starting with WDK 8.0, the driver development environment and the Windows debugger are integrated into Visual Studio. In this integrated environment, most of the tools you need for coding, building, packaging, testing, debugging, and deploying a driver are available in the Visual Studio user interface.

Typically kernel-mode debugging requires two computers. The debugger runs on the *host computer* and the code being debugged runs on the *target computer*. With the Windows debugger integrated into Visual Studio, you can perform a wide variety of debugging tasks, including those shown in the following list, from the host computer.

- Configure a set of target computers for debugging.
- Configure the debugging connections to a set of target computers.
- Launch a kernel-mode debugging session between the host computer and a target computer.
- Debug a user-mode process on the host computer.
- Debug a user-mode process on a target computer.
- Connect to remote debugging sessions.
- View assembly code and source code.
- View and manipulate local variables, parameters, and other symbols.
- View and manipulate memory.
- Navigate call stacks.
- Set breakpoints.
- Execute debugger commands.

You can also build drivers, deploy drivers, and run driver tests from within the Visual Studio user interface. If you make use of the Visual Studio integration provided by both the WDK and Debugging Tools for Windows, you can perform almost all of the driver development, packaging, deployment, testing, and debugging tasks from within Visual Studio on the host computer. Here are some of the WDK capabilities that have been integrated into Visual Studio.

- Configure a set of target computers for driver testing.
- Create and sign a driver package.
- Deploy a driver package to a target computer.

- Install and load a driver on a target computer.
- Test a driver on a target computer.

WinDbg

Microsoft Windows Debugger (WinDbg) is a powerful Windows-based debugger that is capable of both user-mode and kernel-mode debugging. WinDbg provides debugging for the Windows kernel, kernel-mode drivers, and system services, as well as user-mode applications and drivers.

WinDbg uses the Visual Studio debug symbol formats for source-level debugging. It can access any symbol or variable from a module that has PDB symbol files, and can access any public function's name that is exposed by modules that were compiled with COFF symbol files (such as Windows .dbg files).

WinDbg can view source code, set breakpoints, view variables (including C++ objects), stack traces, and memory. Its Debugger Command window allows the user to issue a wide variety of commands.

For kernel-mode debugging, WinDbg typically requires two computers (the host computer and the target computer). WinDbg also supports various remote debugging options for both user-mode and kernel-mode targets.

WinDbg is a graphical-interface counterpart to CDB/NTSD and to KD/NTKD.

KD

Microsoft Kernel Debugger (KD) is a character-based console program that enables in-depth analysis of kernel-mode activity on all NT-based operating systems. You can use KD to debug kernel-mode components and drivers, or to monitor the behavior of the operating system itself. KD also supports multiprocessor debugging.

Typically, KD does not run on the computer being debugged. You need two computers (the *host computer* and the *target computer*) for kernel-mode debugging.

NTKD

There is a variation of the KD debugger named NTKD. It is identical to KD in every way, except that it spawns a new text window when it is started, whereas KD inherits the Command Prompt window from which it was invoked.

CDB

Microsoft Console Debugger (CDB) is a character-based console program that enables low-level analysis of Windows user-mode memory and constructs. CDB is extremely powerful for debugging a program that is currently running or has recently crashed (live analysis), yet simple to set up. It can be used to investigate the behavior of a working application. In the case of a failing application, CDB can be used to obtain a stack trace or to look at the guilty parameters. It works well across a network (using a remote access server), as it is character-based.

With CDB, you can display and execute program code, set breakpoints, and examine and change values in memory. CDB can analyze binary code by disassembling it and displaying assembly instructions. It can also analyze source code directly.

Because CDB can access memory locations through addresses or global symbols, you can refer to data and instructions by name rather than by address, making it easy to locate and debug specific sections of code. CDB supports debugging multiple threads and processes. It is extensible, and can read and write both paged and non-paged memory.

If the target application is itself a console application, the target will share the console window with CDB. To spawn a separate console window for a target console application, use the -2 command-line option.

NTSD

There is a variation of the CDB debugger named Microsoft NT Symbolic Debugger (NTSD). It is identical to CDB in every way, except that it spawns a new text window when it is started, whereas CDB inherits the Command Prompt window from which it was invoked.

Like CDB, NTSD is fully capable of debugging both console applications and graphical Windows programs. (The name *Console Debugger* is used to indicate the fact that CDB is classified as a console application; it does not imply that the target application must be a console application.)

Since the **start** command can also be used to spawn a new console window, the following two constructions will give the same results:

```
start cdb parameters  
ntsd parameters
```

It is possible to redirect the input and output from NTSD (or CDB) so that it can be controlled from a kernel debugger (either Visual Studio, WinDbg, or KD). If this technique is used with NTSD, no console window will appear at all. Controlling NTSD from the kernel debugger is therefore especially useful, since it results in an extremely light-weight debugger that places almost no burden on the computer containing the target application. This combination can be used to debug system processes, shutdown, and the later stages of boot up. See [Controlling the User-Mode Debugger from the Kernel Debugger](#) for details.

Setting Up Debugging (Kernel-Mode and User-Mode)

There are two ways you can set up debugging with the Windows debuggers. You can use Microsoft Visual Studio (integrated with the Windows Driver Kit (WDK)), or you

can do the setup manually. After you set up kernel-mode debugging, you can use Visual Studio, WinDbg, or KD to establish a debugging session. After you set up user-mode debugging, you can use Visual Studio, WinDbg, CDB, or NTSD to establish a debugging session.

Note The Windows debuggers are included in Debugging Tools for Windows. These debuggers are different from the Visual Studio debugger, which is included with Visual Studio. For more information, see [Windows Debugging](#).

Setting Up Kernel-Mode Debugging in Visual Studio

You can use Microsoft Visual Studio to set up and perform kernel-mode debugging of Windows. To use Visual Studio for kernel-mode debugging, you must have the Windows Driver Kit (WDK) integrated with Visual Studio. For information about how to install the integrated environment, see [Windows Driver Development](#).

As an alternative to using Visual Studio to set up kernel-mode debugging, you can do the setup manually. For more information, see [Setting Up Kernel-Mode Debugging Manually](#).

Kernel-mode debugging typically requires two computers. The debugger runs on the *host computer*, and the code being debugged runs on the *target computer*.

Setting Up Kernel-Mode Debugging over a Network Cable in Visual Studio

You can use Microsoft Visual Studio to set up and perform kernel-mode debugging over an Ethernet network. To use Visual Studio for kernel-mode debugging, you must have the Windows Driver Kit (WDK) integrated with Visual Studio. For information about how to install the integrated environment, see [Windows Driver Development](#).

As an alternative to using Visual Studio to set up Ethernet debugging, you can do the setup manually. For more information, see [Setting Up Kernel-Mode Debugging over a Network Cable Manually](#).

Debugging over an Ethernet network has the following advantages compared to debugging over other types of cable:

- The host and target computers can be anywhere on the local network.
- It is easy to debug many target computers from one host computer.
- Network cable is inexpensive and readily available.
- Given any two computers, it is likely that they will both have Ethernet adapters. It is less likely that they will both have serial ports or both have 1394 ports.

The computer that runs the debugger is called the *host computer*, and the computer that is being debugged is called the *target computer*. The host computer must be running Windows XP or later, and the target computer must be running Windows 8 or later.

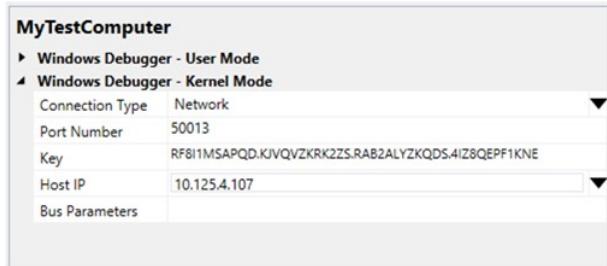

Supported network adapters

The host computer can use any wired or wireless network adapter, but the target computer must use a network adapter that is supported by Debugging Tools for Windows. For

a list of supported network adapters, see [Supported Ethernet NICs for Network Kernel Debugging in Windows 8.1](#).

Configuring the host and target computer

1. Connect the network adapter of the target computer to a network hub or switch using standard CAT5 (or higher-level) network cable. Do not use a crossover cable, and do not use a crossover port in your hub or switch. Connect the network adapter of the host computer to a network hub or switch using a standard cable or a wireless connection.
2. Begin configuring your host and target computers as described in Provision a computer for driver deployment and testing (WDK 8.1).
3. On the host computer, in Visual Studio, when you come to the Computer Configuration dialog box, select **Provision computer** and choose **debugger settings**.
4. For **Connection Type**, choose **Network**.

For **Port Number**, accept the default value or fill in a value of your choice. You can choose any number from 49152 through 65535. The port that you choose will be opened for exclusive access by the debugger running on the host computer. Take care to choose a port number that is not used by any other applications that run on the host computer.

Note The range of port numbers that can be used for network debugging might be limited by your company's network policy. There is no way to tell from the host computer what the limitations are. To determine whether your company's policy limits the range of ports that can be used for network debugging, check with your network administrators.

For **Key**, we strongly recommend that you use the automatically generated default value. However, you can enter your own key if you prefer. For more information, see [Creating your own key](#) later in this topic. For **Host IP**, accept the default value. This is the IP address of your host computer.

If your target computer has only one network adapter, you can leave **Bus Parameters** empty. If there is more than one network adapter on the target computer, use Device Manager on the target computer to determine the PCI bus, device, and function numbers for the adapter you want to use for debugging. For **Bus Parameters**, enter *b.d.f* where *b*, *d*, and *f* are the bus number, device number, and function number of the adapter.

5. The configuration process takes several minutes and might automatically reboot the target computer once or twice. When the process is complete, click **Finish**.

Caution If your target computer is in a docking station, and you have network debugging enabled for a network adapter that is part of the docking station, do not remove the computer from the docking station. If you need to remove the target computer from the docking station, disable kernel debugging first. To disable kernel debugging on the target computer, open a Command Prompt window as Administrator and enter the command **bcedit /debug off**. Reboot the target computer.

Note If you intend to install the Hyper-V role on the target computer, see [Setting Up Network Debugging of a Virtual Machine Host](#).

Verifying dbgsettings on the Target Computer

On the target computer, open a Command Prompt window as Administrator, and enter these commands:

bcedit /dbgsettings

bcedit /enum

```
...
key          RF8...KNE
debugtype    NET
hostip       10.125.5.10
port         50001
dhcp         Yes
...
busparams   0.29.7
...
```

Verify that *debugtype* is **NET** and *port* is the port number you specified in Visual Studio on the host computer. Also verify that *key* is the key that was automatically generated (or you specified) in Visual Studio.

If you entered **Bus Parameters** in Visual Studio, verify that *busparams* matches the bus parameters you specified.

If you do not see the value you entered for **Bus Parameters**, enter this command:

bcedit /set "{dbgsettings}" busparams *b.d.f*

where *b*, *d*, and *f* are the bus, device, and function numbers of the network adapter on the target computer that you have chosen to use for debugging.

For example:

bcedit /set "{dbgsettings}" busparams 0.29.7

Starting the Debugging Session

1. On the host computer, in Visual Studio, on the **Tools** menu, choose **Attach to Process**.
2. For **Transport**, choose **Windows Kernel Mode Debugger**.
3. For **Qualifier**, select the name of the target computer that you previously configured.
4. Click **Attach**.

Allowing the debugger through the firewall

When you first attempt to establish a network debugging connection, you might be prompted to allow the debugging application (Microsoft Visual Studio) through the firewall. Client versions of Windows display the prompt, but Server versions of Windows do not display the prompt. Respond to the prompt by checking the boxes for all three network types: domain, private, and public. If you do not get the prompt, or if you did not check the boxes when the prompt was available, you must use Control Panel to allow access through the firewall. Open **Control Panel > System and Security**, and click **Allow an app through Windows Firewall**. In the list of applications, use the check boxes to allow Visual Studio through the firewall. Restart Visual Studio.

Creating Your Own Key

To keep the target computer secure, packets that travel between the host and target computers must be encrypted. We strongly recommend that you use an automatically generated encryption key (provided by the Visual Studio configuration wizard) when you configure the target computer. However, you can choose to create your own key. Network debugging uses a 256-bit key that is specified as four 64-bit values, in base 36, separated by periods. Each 64-bit value is specified by using up to 13 characters. Valid characters are the letters a through z and the digits 0 through 9. Special characters are not allowed. The following list gives examples of valid (although not strong) keys:

- 1.2.3.4
- abc.123.def.456
- dont.use.previous.keys

Troubleshooting Tips for Debugging over a Network Cable

Debugging application must be allowed through firewall

Your debugger (WinDbg or KD) must have access through the firewall. You can use Control Panel to allow access through the firewall. Open **Control Panel > System and Security**, and click **Allow an app through Windows Firewall**. In the list of applications, use the check boxes to allow Visual Studio through the firewall. Restart Visual Studio.

Port number must be in range allowed by network policy

The range of port numbers that can be used for network debugging might be limited by your company's network policy. To determine whether your company's policy limits the range of ports that can be used for network debugging, check with your network administrator.

Use the following procedure if you need to change the port number.

1. On the host computer, in Visual Studio, on the **Driver** menu, choose **Test > Configure Computers**.
2. Select the name of your test computer, and click **Next**.
3. Select **Provision computer and choose debugger settings**. Click **Next**.
4. For **Port Number**, enter a number that is in the range allowed by your network administrator. Click **Next**.
5. The reconfiguration process takes a few minutes and automatically reboots the target computer. When the process is complete, click **Next** and **Finish**.

Specify busparams if target computer has multiple network adapters

If your target computer has more than one network adapter, you must specify the bus, device, and function numbers of the network adapter that you intend to use for debugging. To specify the bus parameters, open Device Manager, and locate the network adapter that you want to use for debugging. Open the property page for the network adapter, and make a note of the bus number, device number, and function number. In an elevated Command Prompt Window, enter the following command, where *b*, *d*, and *f* are the bus, device and function numbers in decimal format:

```
bcdeedit -set "{dbgsettings}" busparams b.d.f
```

Reboot the target computer.

Setting Up Kernel-Mode Debugging over a 1394 Cable in Visual Studio

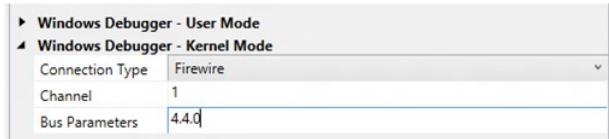

You can use Microsoft Visual Studio to set up and perform kernel-mode debugging over a 1394 (Firewire) cable. To use Visual Studio for kernel-mode debugging, you must have the Windows Driver Kit (WDK) integrated with Visual Studio. For information about how to install the integrated environment, see [Windows Driver Development](#).

As an alternative to using Visual Studio to set up 1394 debugging, you can do the setup manually. For more information, see [Setting Up Kernel-Mode Debugging over a 1394 Cable Manually](#).

The computer that runs the debugger is called the *host computer*, and the computer that is being debugged is called the *target computer*. The host and target computers must each have a 1394 adapter.

Configuring the host and target computers

1. Connect a 1394 cable to the 1394 controllers that you have chosen for debugging on the host and target computers.
2. Begin configuring your host and target computers as described in Provision a computer for driver deployment and testing (WDK 8.1).
3. On the host computer, in Visual Studio, when you get to the Computer Configuration dialog, select **Provision computer and choose debugger settings**.
4. For **Connection Type**, choose **Firewire**.

For **Channel**, enter a decimal number of your choice from 1 through 62.

Note Do not set the channel to 0 when you first set up debugging. Because the default channel value is 0, the software assumes there is no change and does not update the settings. If you must use channel 0, first use an alternate channel (1 through 62) and then switch to channel 0.

If you have more than one 1394 controller on the target computer, enter a **Bus Parameters** value of $b.d.f$, where b , d , and f are the bus, device, and function numbers for the 1394 controller that you intend to use for debugging on the target computer. The bus, device, and function numbers must be in decimal format (example: 4.4.0).

5. The configuration process takes several minutes and might automatically reboot the target computer once or twice. When the process is complete, click **Finish**.

Verifying dbgsettings on the Target Computer

On the target computer, open a Command Prompt window as Administrator, and enter this command:

bcdedit /dbgsettings

bcdedit /enum

```
...
debugtype      1394
debugport      1
baudrate      115200
channel        1
...
busparams      4.0.0
...
```

Verify that *debugtype* is 1394 and *channel* is the channel number you specified in Visual Studio on the host computer. You can ignore the values of *debugport* and *baudrate*; they do not apply to debugging over 1394.

If you entered **Bus Parameters** in Visual Studio, verify that *busparams* matches the bus parameters you specified.

If you do not see the value you entered for **Bus Parameters**, enter this command:

bcdedit /set "{dbgsettings}" busparams b.d.f

where b , d , and f are the bus, device, and function numbers of the 1394 controller on the target computer that you have chosen to use for debugging.

For example:

bcdedit /set "{dbgsettings}" busparams 4.4.0

Starting a Debugging Session for the First Time

1. On the host computer, open Visual Studio as Administrator.
2. On the **Tools** menu, choose **Attach to Process**.
3. For **Transport**, choose **Windows Kernel Mode Debugger**.
4. For **Qualifier**, select the name of the target computer that you previously configured.
5. Click **Attach**.

At this point, the 1394 debug driver gets installed on the host computer. This is why it is important to run Visual Studio as Administrator. After the 1394 debug driver is installed, you do not need to run as Administrator for subsequent debugging sessions.

Starting a Debugging Session

1. On the host computer, in Visual Studio, on the **Tools** menu, choose **Attach to Process**.
2. For **Transport**, choose **Windows Kernel Mode Debugger**.
3. For **Qualifier**, select the name of the target computer that you previously configured.
4. Click **Attach**.

Troubleshooting Tips for Debugging over a 1394 Cable

Most 1394 debugging problems are caused by using multiple 1394 controllers in either the host or target computer. Using multiple 1394 controllers in the host computer is not supported. The 1394 debug driver, which runs on the host, can communicate only with the first 1394 controller enumerated in the registry. If you have a 1394 controller built into the motherboard and a separate 1394 card, either remove the card or disable (by using Device Manager) the built-in controller.

The target computer can have multiple 1394 controllers, although this is not recommended. If your target computer has a 1394 controller on the motherboard, use that

controller for debugging, if possible. If there is an additional 1394 card, you should remove the card and use the onboard controller. Another solution is to disable the onboard 1394 controller in the BIOS settings of the computer.

If you decide to have multiple 1394 controllers enabled on the target computer, you must specify bus parameters so that the debugger knows which controller to claim for debugging. To specify the bus parameters, Open Device Manager, and locate the 1394 controller that you want to use for debugging. Open the property page for the controller, and make a note of the bus number, device number, and function number. In an elevated Command Prompt Window, enter the following command, where *b*, *d*, and *f* are the bus, device and function numbers in decimal format:

```
bcdeedit /set "{dbgsettings}" busparams b.d.f
```

Reboot the target computer.

Setting Up Kernel-Mode Debugging over a USB 3.0 Cable in Visual Studio

You can use Microsoft Visual Studio to set up and perform kernel-mode debugging over a USB 3.0 cable. To use Visual Studio for kernel-mode debugging, you must have the Windows Driver Kit (WDK) integrated with Visual Studio. For information about how to install the integrated environment, see [Windows Driver Development](#).

As an alternative to using Visual Studio to set up USB 3.0 debugging, you can do the setup manually. For more information, see [Setting Up Kernel-Mode Debugging over a USB 3.0 Cable Manually](#).

The computer that runs the debugger is called the *host computer*, and the computer that is being debugged is called the *target computer*.

Debugging over a USB 3.0 connection requires the following hardware:

- A USB 3.0 debug cable. This is an A-A crossover cable that has only the USB 3.0 lines and no Vbus.
- On the host computer, an xHCI (USB 3.0) host controller
- On the target computer, an xHCI (USB 3.0) host controller that supports debugging

Identifying a Debug Port on the Target Computer

1. On the target computer, launch the UsbView tool. The UsbView tool is included in Debugging Tools for Windows.
2. In UsbView, locate all of the xHCI host controllers.
3. In UsbView, expand the nodes of the xHCI host controllers. Look for an indication that a port on the host controller supports debugging.

```
[Port1]
Is Port User Connectable: yes
Is Port Debug Capable: yes
Companion Port Number: 3
Companion Hub Symbolic Link Name: USB#ROOT_HUB30#5&32bab638&0&0\...
Protocols Supported:
  USB 1.1: no
  USB 2.0: no
  USB 3.0: yes
```

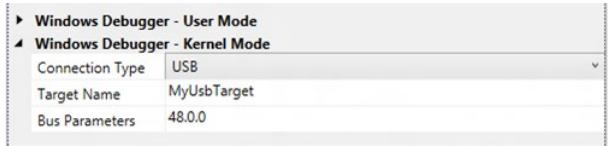

4. Make a note of the bus, device, and function numbers for the xHCI controller that you intend to use for debugging. UsbView displays these numbers. In the following example, the bus number is 48, the device number is 0, and the function number is 0.

```
USB xHCI Compliant Host Controller
...
DriverKey: {36fc9e60-c465-11cf-8056-444553540000}\0020
...
Bus.Device.Function (in decimal): 48.0.0
```

5. After you have identified an xHCI controller that supports debugging, the next step is to locate the physical USB connector that is associated with a port on the xHCI controller. To find the physical connector, plug any USB 3.0 device into any USB connector on the target computer. Refresh UsbView to see where your device is located. If UsbView shows your device connected to the xHCI host controller, then you have found a physical USB connector that you can use for USB 3.0 debugging.

Configuring the host and target computers

1. Begin configuring your host and target computers as described in Provision a computer for driver deployment and testing (WDK 8.1).
2. On the host computer, in Visual Studio, when you come to the Computer Configuration dialog box, select **Provision computer and choose debugger settings**.
3. For **Connection Type**, choose **USB**.

For **Target Name**, enter a string to represent the target computer. This string does not have to be the official name of the target computer; it can be any string that you create as long as it meets these restrictions:

- The maximum length of the string is 24 characters.
- The only characters in the string are the hyphen (-), the underscore(_), the digits 0 through 9, and the letters A through Z (upper or lower case).

If you have more than one USB host controller on the target computer, enter a **Bus Parameters** value of *b.d.f*, where *b*, *d*, and *f* are the bus, device, and function numbers for the USB host controller that you intend to use for debugging on the target computer. The bus, device, and function numbers must be in decimal format (example: 48.0.0).

4. The configuration process takes several minutes and might automatically reboot the target computer once or twice. When the process is complete, click **Finish**.

Verifying dbgsettings on the Target Computer

On the target computer, open a Command Prompt window as Administrator, and enter these commands:

bcdeedit /dbgsettings

bcdeedit /enum

```
...
targetname      MyUsbTarget
debugtype       USB
debugport        1
baudrate        115200
...
busparams       48.0.0
```

Verify that *debugtype* is USB and *targetname* is the name you specified in Visual Studio on the host computer. You can ignore the values of *debugport* and *baudrate*; they do not apply to debugging over USB.

If you entered **Bus Parameters** in Visual Studio, verify that *busparams* matches the bus parameters you specified.

If you do not see the value you entered for **Bus Parameters**, enter this command:

bcdeedit /set "{dbgsettings}" busparams b.d./

where *b*, *d*, and *f* are the bus, device, and function numbers of the xHCI controller on the target computer that you have chosen to use for debugging.

Example:

bcdeedit /set "{dbgsettings}" busparams 48.0.0

Reboot the target computer.

Starting a Debugging Session for the First Time

1. Connect a Universal Serial Bus (USB) 3.0 debug cable to the USB 3.0 ports that you have chosen for debugging on the host and target computers.
2. On the host computer, open Visual Studio as Administrator.
3. On the **Tools** menu, choose **Attach to Process**.
4. For **Transport**, choose **Windows Kernel Mode Debugger**.
5. For **Qualifier**, select the name of the target computer that you previously configured.
6. Click **Attach**.

At this point, the USB debug driver gets installed on the host computer. This is why it is important to run Visual Studio as Administrator. After the USB debug driver is installed, you do not need to run as Administrator for subsequent debugging sessions.

Starting a Debugging Session

1. On the host computer, in Visual Studio, on the **Tools** menu, choose **Attach to Process**.
2. For **Transport**, choose **Windows Kernel Mode Debugger**.
3. For **Qualifier**, select the name of the target computer that you previously configured.
4. Click **Attach**.

Troubleshooting tips for debugging over USB 3.0

In some cases, power transitions can interfere with debugging over USB 3.0. If you have this problem, disable selective suspend for the xHCI host controller (and its root hub) that you are using for debugging.

1. In Device Manager, navigate to the node for the xHCI host controller. Right click the node, and choose **Properties**. If there is a **Power Management** tab, open the tab, and clear the **Allow the computer to turn off this device to save power** check box.
2. In Device Manager, navigate to the node for the root hub of the xHCI host controller. Right click the node, and choose **Properties**. If there is a **Power Management** tab, open the tab, and clear the **Allow the computer to turn off this device to save power** check box.

When you have finished using the xHCI host controller for debugging, enable selective suspend for the xHCI host controller.

Setting Up Kernel-Mode Debugging over a USB 2.0 Cable in Visual Studio

You can use Microsoft Visual Studio to set up and perform kernel-mode debugging over a USB 2.0 cable. To use Visual Studio for kernel-mode debugging, you must have the Windows Driver Kit (WDK) integrated with Visual Studio. For information about how to install the integrated environment, see [Windows Driver Development](#).

As an alternative to using Visual Studio to set up USB 2.0 debugging, you can do the setup manually. For more information, see [Setting Up Kernel-Mode Debugging over a USB 2.0 Cable Manually](#).

The computer that runs the debugger is called the *host computer*, and the computer that is being debugged is called the *target computer*.

Debugging over a USB 2.0 connection requires the following hardware:

- A Universal Serial Bus (USB) 2.0 debug cable. This cable is not a standard USB 2.0 cable, because it has an extra hardware component that makes it compatible with the USB2 Debug Device Functional Specification. You can find these cables by doing an Internet search for "USB 2.0 debug cable".
- On the host computer, an EHCI (USB 2.0) host controller
- On the target computer, an EHCI (USB 2.0) host controller that supports debugging

Identifying a Debug Port on the Target Computer

1. On the target computer, launch the UsbView tool. The UsbView tool is included in Debugging Tools for Windows.
2. In UsbView, locate all of the host controllers that are compatible with the EHCI specification. For example, you could look for controllers that are listed as Enhanced.
3. In UsbView, expand the nodes of the EHCI host controllers. Look for an indication that a host controller supports debugging, and look for the number of the debug port. For example, UsbView displays this output for an EHCI host controller that supports debugging on port 1.

```
XXX XXX XXX USB2 Enhanced Host Controller - 293A
...
Debug Port Number: 1
Bus.Device.Function (in decimal): 0.29.7
```

Note Many EHCI host controllers support debugging on port 1, but some EHCI host controllers support debugging on port 2.

4. Make a note of the bus, device, and function numbers for the EHCI controller that you intend to use for debugging. UsbView displays these numbers. In the preceding example, the bus number is 0, the device number is 29, and the function number is 7.
5. After you have identified the EHCI controller and the port number that supports debugging, the next step is to locate the physical USB connector that is associated with the correct port number. To find the physical connector, plug any USB 2.0 device into any USB connector on the target computer. Refresh UsbView to see where your device is located. If UsbView shows your device connected to the EHCI host controller and port that you identified as the debug port, then you have found a physical USB connector that you can use for debugging. It could be that there is no external physical USB connector that is associated with a debug port on an EHCI controller. In that case, you can look for a physical USB connector inside the computer. Perform the same steps to determine whether the internal USB connector is suitable for kernel debugging. If you cannot find a physical USB connector (either external or internal) that is associated with a debug port, then you cannot use the computer as a target for debugging over a USB 2.0 cable.

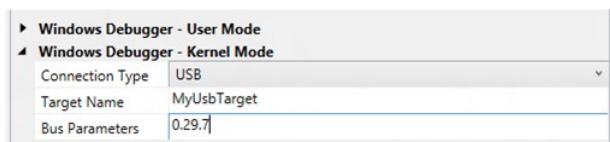

Note See [this remark](#) for an exception.

Connecting the USB debug cable

1. Verify that the host computer is not configured to be the target of USB debugging. (If necessary, open a Command Prompt window as Administrator, enter **bcdeedit /debug off**, and reboot.)
2. On the host computer, use UsbView to find the EHCI host controllers and ports that support debugging. If possible, plug one end of the USB 2.0 debug cable into an EHCI port (on the host computer) that does not support debugging. Otherwise, plug the cable into any EHCI port on the host computer.
3. Plug the other end of the USB 2.0 debug cable into the connector that you identified previously on the target computer.

Configuring the host and target computers

1. Begin configuring your host and target computers as described in Provision a computer for driver deployment and testing (WDK 8.1).
2. On the host computer, in Visual Studio, when you come to the Computer Configuration dialog box, select **Provision computer and choose debugger settings**.
3. For **Connection Type**, choose **USB**.

For **Target Name**, enter a string to represent the target computer. This string does not have to be the official name of the target computer; it can be any string that you

create as long as it meets these restrictions:

- The maximum length of the string is 24 characters.
- The only characters in the string are the hyphen (-), the underscore(_), the digits 0 through 9, and the letters A through Z (upper or lower case).

If you have more than one USB host controller on the target computer, enter a **Bus Parameters** value of *b.d.f*, where *b*, *d*, and *f* are the bus, device, and function numbers for the USB host controller that you intend to use for debugging on the target computer. The bus, device, and function numbers must be in decimal format (example: 0.29.7).

4. The configuration process takes several minutes and might automatically reboot the target computer once or twice. When the process is complete, click **Finish**.

Verifying dbgsettings on the Target Computer

On the target computer, open a Command Prompt window as Administrator, and enter these commands:

bcedit /dbgsettings

bcedit /enum

```
...
targetname      MyUsbTarget
debugtype       USB
debugport        1
baudrate        115200
...
busparams       0.29.7
...
```

Verify that *debugtype* is USB and *targetname* is the name you specified in Visual Studio on the host computer. You can ignore the values of *debugport* and *baudrate*; they do not apply to debugging over USB.

If you entered **Bus Parameters** in Visual Studio, verify that *busparams* matches the bus parameters you specified.

If you do not see the value you entered for **Bus Parameters**, enter this command:

bcedit /set "{dbgsettings}" busparams *b.d.f*

where *b*, *d*, and *f* are the bus, device, and function numbers of the EHCI controller on the target computer that you have chosen to use for debugging.

Example:

bcedit /set "{dbgsettings}" busparams 0.29.7

Reboot the target computer.

Starting a Debugging Session for the First Time

1. Connect a USB 2.0 debug cable to the USB 2.0 ports that you have chosen for debugging on the host and target computers.
2. On the host computer, open Visual Studio as Administrator.
3. On the **Tools** menu, choose **Attach to Process**.
4. For **Transport**, choose **Windows Kernel Mode Debugger**.
5. For **Qualifier**, select the name of the target computer that you previously configured.
6. Click **Attach**.

At this point, the USB debug driver gets installed on the host computer. This is why it is important to run Visual Studio as Administrator. After the USB debug driver is installed, you do not need to run as Administrator for subsequent debugging sessions.

Starting a Debugging Session

1. On the host computer, in Visual Studio, on the **Tools** menu, choose **Attach to Process**.
2. For **Transport**, choose **Windows Kernel Mode Debugger**.
3. For **Qualifier**, select the target name that you entered during configuration.
4. Click **Attach**.

Setting Up Kernel-Mode Debugging over a Serial Cable in Visual Studio

You can use Microsoft Visual Studio to set up and perform kernel-mode debugging over a null-modem cable. Null-modem cables are serial cables that have been configured to send data between two serial ports. They are available at most computer stores. Do not confuse null-modem cables with standard serial cables. Standard serial cables do not connect serial ports to each other. For information about how null-modem cables are wired, see [Null-Modem Cable Wiring](#).

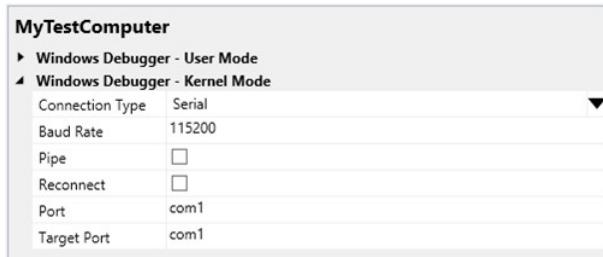

To use Visual Studio for kernel-mode debugging, you must have the Windows Driver Kit (WDK) integrated with Visual Studio. For information about how to install the integrated environment, see [Windows Driver Development](#).

As an alternative to using Visual Studio to set up serial debugging, you can do the setup manually. For more information, see [Setting Up Kernel-Mode Debugging over a Serial Cable Manually](#).

The computer that runs the debugger is called the *host computer*, and the computer being debugged is called the *target computer*.

Configuring the host and target computers

1. Begin configuring your host and target computer as described in Provision a computer for driver deployment and testing (WDK 8.1).
2. On the host computer, in Visual Studio, when you come to the Computer Configuration dialog box, select **Provision computer and choose debugger settings**.
3. For **Connection Type**, choose **Serial**.

For **Baud Rate**, accept the default value or enter the baud rate you want to use. For **Port**, enter the name of the COM port that you want to use for debugging on the host computer. For **Target Port**, enter the name of the COM port that you want to use for debugging on the target computer.

4. The configuration process takes several minutes and might automatically reboot the target computer once or twice. When the process is complete, click **Finish**.

Starting the Debugging Session

1. Connect the null-modem cable to the COM ports that you have chosen for debugging on the host and target computers.
2. On the host computer, in Visual Studio, on the **Tools** menu, choose **Attach to Process**.
3. For **Transport**, choose **Windows Kernel Mode Debugger**.
4. For **Qualifier**, select the name of the target computer that you previously configured.
5. Click **Attach**.

Troubleshooting Tips for Debugging over a Serial Cable

Specify correct COM ports and baud rate

Determine the numbers of the COM ports you are using for debugging on the host and target computers. For example, suppose you have your null-modem cable connected to COM1 on the host computer and COM2 on the target computer. Also suppose you have chosen a baud rate of 115200.

1. On the host computer, in Visual Studio, on the **Driver** menu, choose **Test > Configure Computers**.
2. Select the name of your test computer, and click **Next**.
3. Select **Provision computer and choose debugger settings**. Click **Next**.
4. If you are using COM1 on the host computer, for **Port**, enter com1. If you are using COM2 on the target computer, for **Target Port**, enter com2.
5. If you have chosen to use a baud rate of 115200, for **Baud Rate**, enter 115200.

You can double check the COM port and baud rate settings on the target computer by opening a Command Prompt window as Administrator, and entering **bcdedit /dbgsettings**. If you are using COM2 on the target computer and a baud rate of 115200, the output of **bcdedit** should show **debugport 2** and **baudrate 115200**.

Null Modem Cable Wiring

The following tables show how null-modem cables are wired.

9-pin connector

Connector 1	Connector 2	Signals
2	3	Tx - Rx
3	2	Rx - Tx
7	8	RTS - CTS
8	7	CTS - RTS
4	1+6	DTR - (CD+DSR)
1+6	4	(CD+DSR) - DTR
5	5	Signal ground

25-pin connector

Connector 1	Connector 2	Signals
2	3	Tx - Rx
3	2	Rx - Tx
4	5	RTS - CTS

5	4	CTS - RTS
6	20	DSR - DTR
20	6	DTR - DSR
7	7	Signal ground

Signal Abbreviations

Abbreviation	Signal
Tx	Transmit data
Rx	Receive data
RTS	Request to send
CTS	Clear to send
DTR	Data terminal ready
DSR	Data set ready
CD	Carrier detect

Setting Up Kernel-Mode Debugging using Serial over USB in Visual Studio

The [Sharks Cove development board](#) supports serial debugging over a USB cable.

To use Microsoft Visual Studio for kernel-mode debugging, you must have the Windows Driver Kit (WDK) integrated with Visual Studio. For information about how to install the integrated environment, see [Windows Driver Kit \(WDK\)](#).

As an alternative to using Visual Studio to set up serial debugging over a USB cable, you can do the setup manually. For more information, see [Setting Up Kernel-Mode Debugging using Serial over USB Manually](#).

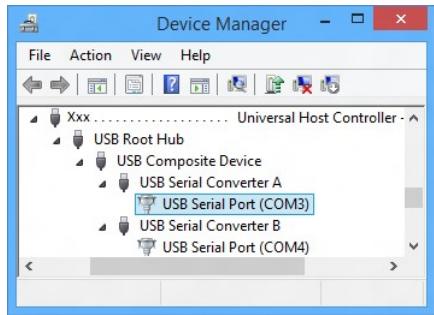

The computer that runs the debugger is called the *host computer*, and the computer being debugged is called the *target computer*. In this topic, the Sharks Cove board is the target computer.

Setting up a Host Computer for debugging the Sharks Cove board

1. On the host computer, open Device Manager. On the **View** menu, choose **Devices by Type**.
2. On the Sharks Cove board, locate the debug connector. This is the micro USB connector shown in the following picture.

3. Use a USB 2.0 cable to connect the host computer to the debug connector on the Sharks cove board.
4. On the host computer, in Device Manager, two COM ports will get enumerated. Select the lowest numbered COM port. On the **View** menu, choose **Devices by Connection**. Verify that the COM port is listed under one of the USB host controllers.

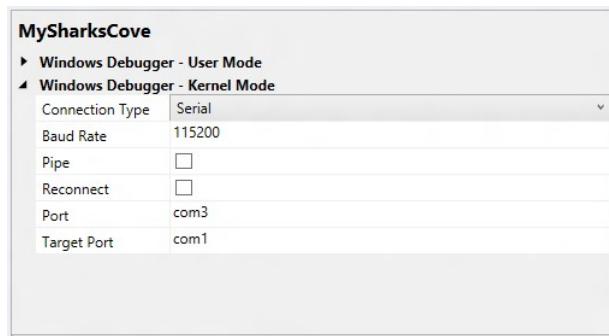

Make a note of the COM port number. This is the lowest COM port number that shows under the USB host controller node. For example, in the preceding screen shot, the lowest COM port number under the USB host controller is COM3. You will need this COM port number later when you start a debugging session. If the driver is not already installed for the COM port, right click the COM port node, and choose **Update Driver**. Then select **Search automatically for updated driver software**. You will need an internet connection for this.

Configuring the host and target computers

In these steps, the Sharks Cove board is the target computer.

1. Begin configuring your host and target computer as described in Provision a computer for driver deployment and testing (WDK 8.1).
2. On the host computer, in Visual Studio, when you come to the Computer Configuration dialog box, select **Provision computer and choose debugger settings**.
3. For **Connection Type**, choose **Serial**.

For **Baud Rate**, enter 115200. For **Port**, enter the name of the COM port that you noted previously in Device Manager (for example, com3). For **Target Port**, enter com1.

4. The configuration process takes several minutes and might automatically reboot the target computer once or twice. When the process is complete, click **Finish**.

Starting the Debugging Session

1. On the host computer, in Visual Studio, on the **Tools** menu, choose **Attach to Process**.
2. For **Transport**, choose **Windows Kernel Mode Debugger**.
3. For **Qualifier**, select the name of the target computer that you previously configured.
4. Click **Attach**.

Troubleshooting Tips for Serial Debugging over a USB Cable

Specify correct COM port on both host and target

On the target computer (Sharks Cove board), verify that you are using COM1 for debugging. Open a Command Prompt window as Administrator, and enter **bcedit /dbgsettings**. The output of **bcedit** should show **debugport 1**.

On the host computer, verify that you are using the COM port that you noted earlier in Device Manager.

1. On the host computer, in Visual Studio, on the **Driver** menu, choose **Test > Configure Computers**.
2. Select the name of your test computer, and click **Next**.
3. Select **Provision computer and choose debugger settings**. Click **Next**.
4. Verify that the correct COM port number is listed for **Port**.

Baud rate must be the same on host and target

The baud rate must be 115200 on both the host and target computers.

On the target computer (Sharks Cove board), open a Command Prompt window as Administrator, and enter **bcedit /dbgsettings**. The output of **bcedit** should show **baudrate 115200**.

On the host computer, verify that you are using a baud rate of 115200.

1. On the host computer, in Visual Studio, on the **Driver** menu, choose **Test > Configure Computers**.
2. Select the name of your test computer, and click **Next**.

3. Select **Provision computer and choose debugger settings**. Click **Next**.
4. Verify that the **Baud Rate** is 115200.

Setting Up Kernel-Mode Debugging of a Virtual Machine in Visual Studio

You can use Microsoft Visual Studio to set up and perform kernel-mode debugging of a virtual machine. The virtual machine can be located on the same physical computer as the debugger or on a different computer that is connected to the same network. To use Visual Studio for kernel-mode debugging, you must have the Windows Driver Kit (WDK) integrated with Visual Studio. For information about how to install the integrated environment, see [Windows Driver Development](#).

As an alternative to using Visual Studio to set up debugging of a virtual machine, you can do the setup manually. For more information, see [Setting Up Kernel-Mode Debugging of a Virtual Machine Manually](#).

The computer that runs the debugger is called the *host computer*, and the virtual machine that is being debugged is called the *target virtual machine*.

Configuring the Target Virtual Machine

1. In the virtual machine, in an elevated Command Prompt window, enter the following commands.

```
bcedit /debug on  
bcedit /dbgsettings serial debugport:n baudrate:115200
```

where *n* is the number of a COM port on the virtual machine.

Note By default, COM ports are not presented in generation 2 virtual machines. For information about how to create a COM port, see [Generation 2 Virtual Machines](#).

2. Reboot the virtual machine.
3. In the virtual machine, configure the COM port to map to a named pipe. The debugger will connect through this pipe. For more information about how to create this pipe, see your virtual machine's documentation.

Configuring the Host Computer

The host computer can be the same physical computer that is running the virtual machine, or it can be a separate computer.

1. On the host computer, in Visual Studio, on the **Driver** menu, choose **Test > Configure Computer**.
2. Click **Add New Computer**.
3. For **Computer name**, enter the name of the physical computer that is running the target virtual machine.
4. Select **Manually configure debuggers and do not provision**, and click **Next**.
5. For **Connection Type**, select **Serial**.
6. Check **Pipe**, and check **Reconnect**.
7. If the debugger is running on the same computer as the virtual machine, enter the following for **Pipe name**:

`\.\pipe\PipeName`.

If the debugger is running on a different computer from the virtual machine, enter the following for **Pipe name**:

`\VMHost\pipe\PipeName`

where, *VMHost* is the name of the physical computer that is running the target virtual machine, and *PipeName* is the name of the pipe that you associated with the COM port on the target virtual machine.

8. Click **Next**. Click **Finish**.

Starting the Debugging Session

1. On the host computer, in Visual Studio, on the **Tools** menu, choose **Attach to Process**.
2. For **Transport**, choose **Windows Kernel Mode Debugger**.
3. For **Qualifier**, select the name of the physical computer that is running the target virtual machine.
4. Click **Attach**.

Generation 2 Virtual Machines

By default, COM ports are not presented in generation 2 virtual machines. You can add COM ports through PowerShell or WMI. For the COM ports to be displayed in the Hyper-V Manager console, they must be created with a path.

To enable kernel debugging using a COM port on a generation 2 virtual machine, follow these steps:

1. Disable Secure Boot by entering this PowerShell command:

Set-VMFirmware –Vmname VmName –EnableSecureBoot Off

where *VmName* is the name of your virtual machine.

2. Add a COM port to the virtual machine by entering this PowerShell command:

Set-VMComPort –VMName VmName 1 \\.\pipe\PipeName

For example, the following command configures the first COM port on virtual machine TestVM to connect to named pipe TestPipe on the local computer.

Set-VMComPort –VMName TestVM 1 \\.\pipe\TestPipe

For more information, see [Generation 2 Virtual Machine Overview](#).

Setting Up Kernel-Mode Debugging over a Network Cable Manually

Debugging Tools for Windows supports kernel debugging over an Ethernet network. This topic describes how to set up Ethernet debugging manually.

As an alternative to setting up Ethernet debugging manually, you can do the setup using Microsoft Visual Studio. For more information, see [Setting Up Kernel-Mode Debugging over a Network Cable in Visual Studio](#).

The computer that runs the debugger is called the *host computer*, and the computer being debugged is called the *target computer*. The host computer must be running Windows XP or later, and the target computer must be running Windows 8 or later.

Debugging over a network has the following advantages compared to debugging over other types of cable.

- The host and target computers can be anywhere on the local network.
- It is easy to debug many target computers from one host computer.
- Network cable is inexpensive and readily available.
- Given any two computers, it is likely that they will both have Ethernet adapters. It is less likely that they will both have serial ports or both have 1394 ports.

Supported Network Adapters

The host computer can use any network adapter, but the target computer must use a network adapter that is supported by Debugging Tools for Windows. For a list of supported network adapters, see [Supported Ethernet NICs for Network Kernel Debugging in Windows 8.1](#).

Determining the IP Address of the Host Computer

Use one of the following procedures to determine the IP address of the host computer.

- On the host computer, open a Command Prompt window and enter the following command:

```
ipconfig
```

Make a note of the IPv4 address of the network adapter that you intend to use for debugging.

- On the target computer, open a Command Prompt window and enter the following command, where *HostName* is the name of the host computer:

```
ping -4 HostName
```

Choosing a Port for Network Debugging

Choose a port number that will be used for debugging on both the host and target computers. You can choose any number from 49152 through 65535. The port that you choose will be opened for exclusive access by the debugger running on the host computer. Take care to choose a port number that is not used by any other applications that run on the host computer.

Note The range of port numbers that can be used for network debugging might be limited by your company's network policy. There is no way to tell from the host computer what the limitations are. To determine whether your company's policy limits the range of ports that can be used for network debugging, check with your network administrators.

If you connect several target computers to a single host computer, each connection must have a unique port number. For example, if you connect 100 target computers to a single host computer, you can assign port 50000 to the first connection, port 50001 to the second connection, port 50002 to the third connection, and so on.

Note A different host computer could use the same range of ports (50000 through 50099) to connect to another 100 target computers.

Setting Up the Target Computer

1. Verify that the target computer has a supported network adapter.
2. Connect the supported adapter to a network hub or switch using standard CAT5 or better network cable. Do not use a crossover cable, and do not use a crossover port in your hub or switch.
3. In an elevated Command Prompt window, enter the following commands, where *w.x.y.z* is the IP address of the host computer, and *n* is a port number of your choice:

```
bcdedit /debug on  
bcdedit /dbgsettings net hostip:w.x.y.z port:n
```

4. **bcdedit** will display an automatically generated key. Copy the key and store it on a removable storage device like a USB flash drive. You will need the key when you start a debugging session on the host computer.

Note We strongly recommend that you use an automatically generated key. However, you can create your own key as described later in the Creating Your Own Key section.

5. If there is more than one network adapter in the target computer, use Device Manager to determine the PCI bus, device, and function numbers for the adapter you want to use for debugging. Then in an elevated Command Prompt window, enter the following command, where *b*, *d*, and *f* are the bus number, device number, and function number of the adapter:

```
bcdedit /set "{dbgsettings}" busparams b.d.f  
6. Reboot the target computer.
```

Caution If your target computer is in a docking station, and you have network debugging enabled for a network adapter that is part of the docking station, do not remove the computer from the docking station. If you need to remove the target computer from the docking station, disable kernel debugging first. To disable kernel debugging on the target computer, open a Command Prompt window as Administrator and enter the command **bcdedit /debug off**. Reboot the target computer.

Note If you intend to install the Hyper-V role on the target computer, see [Setting Up Network Debugging of a Virtual Machine Host](#).

Setting Up the Host Computer

Connect the network adapter of the host computer to a network hub or switch using standard CAT5 (or higher-level) network cable. Do not use a crossover cable, and do not use a crossover port in your hub or switch.

Starting the Debugging Session

Using WinDbg

On the host computer, open WinDbg. On the **File** menu, choose **Kernel Debug**. In the Kernel Debugging dialog box, open the **Net** tab. Enter your port number and key. Click **OK**.

You can also start a session with WinDbg by opening a Command Prompt window and entering the following command, where *n* is your port number and *Key* is the key that was automatically generated by **bcdedit** when you set up the target computer:

```
windbg -k net:port=n,key=Key
```

If you are prompted about allowing WinDbg to access the port through the firewall, allow WinDbg to access the port for all the different network types.

Using KD

On the host computer, open a Command Prompt window. Enter the following command, where *n* is your port number and *Key* is the key that was automatically generated by **bcdedit** when you set up the target computer:

```
kd -k net:port=n,Key=Key
```

If you are prompted about allowing KD to access the port through the firewall, allow KD to access the port for all the different network types.

Allowing the debugger through the firewall

When you first attempt to establish a network debugging connection, you might be prompted to allow the debugging application (WinDbg or KD) access through the firewall. Client versions of Windows display the prompt, but Server versions of Windows do not display the prompt. You should respond to the prompt by checking the boxes for all three network types: domain, private, and public. If you do not get the prompt, or if you did not check the boxes when the prompt was available, you must use Control Panel to allow access through the firewall. Open **Control Panel > System and Security**, and click **Allow an app through Windows Firewall**. In the list of applications, locate Windows GUI Symbolic Debugger and Windows Kernel Debugger. Use the check boxes to allow those two applications through the firewall. Restart your debugging application (WinDbg or KD).

How the Debugger Obtains an IP Address for the Target Computer

The kernel debugging driver on the target computer attempts to use Dynamic Host Configuration Protocol (DHCP) to get a routable IP address for the network adapter that is being used for debugging. If the driver obtains a DHCP-assigned address, then the target computer can be debugged by host computers located anywhere on the network. If the driver fails to obtain a DHCP-assigned address, it uses Automatic Private IP Addressing (APIPA) to obtain a local link IP address. Local link IP addresses are not routable, so a host and target cannot use a local link IP address to communicate through a router. In that case, network debugging will work if you plug the host and target computers into the same network hub or switch.

Creating Your Own Key

To keep the target computer secure, packets that travel between the host and target computers must be encrypted. We strongly recommend that you use an automatically generated encryption key (provided by **bcdedit** when you configure the target computer). However, you can choose to create your own key. Network debugging uses a 256-bit key that is specified as four 64-bit values, in base 36, separated by periods. Each 64-bit value is specified by using up to 13 characters. Valid characters are the letters a through z and the digits 0 through 9. Special characters are not allowed. The following list gives examples of valid (although not strong) keys:

- 1.2.3.4
- abc.123.def.456
- dont.use.previous.keys

To specify your own key, open an elevated Command Prompt window on the target computer. Enter the following command, where *w.x.y.z* is the IP address of the host computer, and *n* is your port number, and *Key* is your key:

```
bcdedit /dbgsettings net hostip:w.x.y.z port:n key:Key
```

Reboot the target computer.

Troubleshooting Tips for Debugging over a Network Cable

Debugging application must be allowed through firewall

Your debugger (WinDbg or KD) must have access through the firewall. You can use Control Panel to allow access through the firewall. Open **Control Panel > System and Security**, and click **Allow an app through Windows Firewall**. In the list of applications, locate Windows GUI Symbolic Debugger and Windows Kernel Debugger. Use the check boxes to allow those two applications through the firewall. Restart your debugging application (WinDbg or KD).

Port number must be in range allowed by network policy

The range of port numbers that can be used for network debugging might be limited by your company's network policy. To determine whether your company's policy limits the range of ports that can be used for network debugging, check with your network administrator. On the target computer, open a Command Prompt window as Administrator and enter the command **bcdedit /dbgsettings**. The output will be similar to this.

key	XXXXXX.XXXX.XXXX.XXXX
debugtype	NET
debugport	1
baudrate	115200
hostip	10.125.4.86
port	50085

Notice the value of **port**. For example, in the preceding output, the value of **port** is 50085. If the value of **port** lies outside the range allowed by your network administrator, enter the following command, where *w.x.y.z* is the IP address of the host computer, and *n* is a port number in the allowed range

```
bcdedit /dbgsettings net hostip:w.x.y.z port:n
```

Reboot the target computer.

Note In the preceding output from **bcdedit**, the debugport and baudrate entries do not apply to debugging over a network cable. Those entries apply to debugging over a serial cable, but they sometimes appear even though the target is configured for debugging over a network cable.

Specify busparams if target computer has multiple network adapters

If your target computer has more than one network adapter, you must specify the bus, device, and function numbers of the network adapter that you intend to use for debugging. To specify the bus parameters, Open Device Manager, and locate the network adapter that you want to use for debugging. Open the property page for the network adapter, and make a note of the bus number, device number, and function number. In an elevated Command Prompt Window, enter the following command, where *b*, *d*, and *f* are the bus, device and function numbers in decimal format:

```
bcdedit /set "{dbgsettings}" busparams b.d.f
```

Reboot the target computer.

Setting Up Kernel-Mode Debugging over a 1394 Cable Manually

Debugging Tools for Windows supports kernel debugging over a 1394 (Firewire) cable. This topic describes how to set up 1394 debugging manually.

As an alternative to setting up 1394 debugging manually, you can do the setup using Microsoft Visual Studio. For more information, see [Setting Up Kernel-Mode Debugging over a 1394 Cable in Visual Studio](#).

The computer that runs the debugger is called the *host computer*, and the computer being debugged is called the *target computer*. The host and target computers must each have a 1394 adapter and must be running Windows XP or later. The host and target computers do not have to be running the same version of Windows.

Setting Up the Target Computer

1. Connect a 1394 cable to the 1394 controllers that you have chosen for debugging on the host and target computers.
2. In an elevated Command Prompt window, enter the following commands, where *n* is a channel number of your choice, from 0 through 62:

bcedit /debug on

bcedit /dbgsettings 1394 channel:*n*

3. If there is more than one 1394 controller on the target computer, you must specify the bus, device, and function numbers of the 1394 controller that you intend to use for debugging. For more information, see [Troubleshooting Tips for 1394 Debugging](#).
4. Do not reboot the target computer yet.

Starting a Debugging Session for the First Time

1. Determine the bitness (32-bit or 64-bit) of Windows running on the host computer.
2. On the host computer, open a version of WinDbg (as Administrator) that matches the bitness of Windows running on the host computer. For example, if the host computer is running a 64-bit version of Windows, open the 64-bit version of WinDbg as Administrator.
3. On the **File** menu, choose **Kernel Debug**. In the Kernel Debugging dialog box, open the **1394** tab. Enter your channel number, and click **OK**.

At this point, the 1394 debug driver gets installed on the host computer. This is why it is important to match the bitness of WinDbg to the bitness of Windows. After the 1394 debug driver is installed, you can use either the 32-bit or 64-bit version of WinDbg for subsequent debugging sessions.

4. Reboot the target computer.

Starting a Debugging Session

Using WinDbg

- On the host computer, open WinDbg. On the **File** menu, choose **Kernel Debug**. In the Kernel Debugging dialog box, open the **1394** tab. Enter your channel number, and click **OK**.

You can also start a session with WinDbg by entering the following command in a Command Prompt window, where *n* is your channel number:

windbg /k 1394:channel=*n*

Using KD

- On the host computer, open a Command Prompt window and enter the following command, where *n* is your channel number:

kd /k 1394:channel=*n*

Using Environment Variables

On the host computer, you can use environment variables to specify the 1394 channel. Then you do not have to specify the channel each time you start a debugging session. To use environment variables to specify the 1394 channel, open a Command Prompt window and enter the following commands, where *n* is your channel number:

- **set _NT_DEBUG_BUS=1394**
- **set _NT_DEBUG_1394_CHANNEL=*n***

To start a debugging session, open a Command Prompt window and enter one of the following commands:

- **kd**
- **windbg**

Additional Information

For complete documentation of the **bcdeedit** command and the boot.ini file, see Boot Options for Driver Testing and Debugging in the Windows Driver Kit (WDK) documentation.

Troubleshooting Tips for Debugging over a 1394 Cable

Most 1394 debugging problems are caused by using multiple 1394 controllers in either the host or target computer. Using multiple 1394 controllers in the host computer is not supported. The 1394 debug driver, which runs on the host, can communicate only with the first 1394 controller enumerated in the registry. If you have a 1394 controller built into the motherboard and a separate 1394 card, either remove the card or disable the built-in controller in the BIOS settings of the computer.

The target computer can have multiple 1394 controllers, although this is not recommended. If your target computer has a 1394 controller on the motherboard, use that controller for debugging, if possible. If there is an additional 1394 card, you should remove the card and use the onboard controller. Another solution is to disable the onboard 1394 controller in the BIOS settings of the computer.

If you decide to have multiple 1394 controllers enabled on the target computer, you must specify bus parameters so that the debugger knows which controller to claim for debugging. To specify the bus parameters, Open Device Manager on the target computer, and locate the 1394 controller that you want to use for debugging. Open the property page for the controller, and make a note of the bus number, device number, and function number. In an elevated Command Prompt Window, enter the following command, where *b*, *d*, and *f* are the bus, device and function numbers in decimal format:

```
bcdeedit -set "{dbgsettings}" busparams b.d.f.
```

Reboot the target computer.

Setting Up Kernel-Mode Debugging over a USB 3.0 Cable Manually

Debugging Tools for Windows supports kernel debugging over a USB 3.0 cable. This topic describes how to set up USB 3.0 debugging manually.

As an alternative to setting up USB 3.0 debugging manually, you can do the setup using Microsoft Visual Studio. For more information, see [Setting Up Kernel-Mode Debugging over a USB 3.0 Cable in Visual Studio](#).

The computer that runs the debugger is called the *host computer*, and the computer being debugged is called the *target computer*.

Debugging over a USB 3.0 cable requires the following hardware:

- A USB 3.0 debug cable. This is an A-A crossover cable that has only the USB 3.0 lines and no Vbus.
- On the host computer, an xHCI (USB 3.0) host controller
- On the target computer, an xHCI (USB 3.0) host controller that supports debugging

Setting Up the Target Computer

1. On the target computer, launch the UsbView tool. The UsbView tool is included in Debugging Tools for Windows.
2. In UsbView, locate all of the xHCI host controllers.
3. In UsbView, expand the nodes of the xHCI host controllers. Look for an indication that a port on the host controller supports debugging.

```
[Port1]
Is Port User Connectable: yes
Is Port Debug Capable: yes
Companion Port Number: 3
Companion Hub Symbolic Link Name: USB#ROOT_HUB30#5&32bab638&0&0#(...)
Protocols Supported:
  USB 1.1: no
  USB 2.0: no
  USB 3.0: yes
```

4. Make a note of the bus, device, and function numbers for the xHCI controller that you intend to use for debugging. UsbView displays these numbers. In the following example, the bus number is 48, the device number is 0, and the function number is 0.
- ```
USB xHCI Compliant Host Controller
...
DriverKey: {36fc9e60-c465-11cf-8056-444553540000}\0020
...
Bus.Device.Function (in decimal): 48.0.0
```
5. After you have identified an xHCI controller that supports debugging, the next step is to locate the physical USB connector that is associated with a port on the xHCI controller. To find the physical connector, plug any USB 3.0 device into any USB connector on the target computer. Refresh UsbView to see where your device is located. If UsbView shows your device connected to your chosen xHCI host controller, then you have found a physical USB connector that you can use for USB 3.0 debugging.
  6. On the target computer, open a Command Prompt window as Administrator, and enter these commands:

```
bcdeedit /debug on
```

```
bcedit /dbgsettings usb targetname:<TargetName>
```

where *TargetName* is a name that you create for the target computer. Note that *TargetName* does not have to be the official name of the target computer; it can be any string that you create as long as it meets these restrictions:

- The maximum length of the string is 24 characters.
- The only characters in the string are the hyphen (-), the underscore(\_), the digits 0 through 9, and the letters A through Z (upper or lower case).

7. If you have more than one USB host controller on the target computer, enter this command:

```
bcedit /set "{dbgsettings}" busparams b.d.f
```

where *b*, *d*, and *f* are the bus, device, and function numbers for the USB host controller that you intend to use for debugging. The bus, device, and function numbers must be in decimal format.

Example:

```
bcedit /set "{dbgsettings}" busparams 48.0.0
```

8. Reboot the target computer.

## Starting a Debugging Session for the First Time

1. Connect a Universal Serial Bus (USB) 3.0 debug cable to the USB 3.0 ports that you have chosen for debugging on the host and target computers.
2. Determine the bitness (32-bit or 64-bit) of Windows running on the host computer.
3. On the host computer, open a version of WinDbg (as Administrator) that matches the bitness of Windows running on the host computer. For example, if the host computer is running a 64-bit version of Windows, open the 64-bit version of WinDbg as Administrator.
4. On the **File** menu, choose **Kernel Debug**. In the Kernel Debugging dialog box, open the **USB** tab. Enter the target name that you created when you set up the target computer. Click **OK**.

At this point, the USB debug driver gets installed on the host computer. This is why it is important to match the bitness of WinDbg to the bitness of Windows. After the USB debug driver is installed, you can use either the 32-bit or 64-bit version of WinDbg for subsequent debugging sessions.

## Starting a Debugging Session

### Using WinDbg

On the host computer, open WinDbg. On the **File** menu, choose **Kernel Debug**. In the Kernel Debugging dialog box, open the **USB** tab. Enter the target name that you created when you set up the target computer. Click **OK**.

You can also start a session with WinDbg by entering the following command in a Command Prompt window, where *TargetName* is the target name you created when you set up the target computer:

```
windbg /k usb:targetname=<TargetName>
```

### Using KD

On the host computer, open a Command Prompt window and enter the following command, where *TargetName* is the target name you created when you set up the target computer:

```
kd /k usb:targetname=<TargetName>
```

## Troubleshooting tips for debugging over USB 3.0

In some cases, power transitions can interfere with debugging over USB 3.0. If you have this problem, disable selective suspend for the xHCI host controller (and its root hub) that you are using for debugging.

1. In Device Manager, navigate to the node for the xHCI host controller. Right click the node, and choose **Properties**. If there is a **Power Management** tab, open the tab, and clear the **Allow the computer to turn off this device to save power** check box.
2. In Device Manager, navigate to the node for the root hub of the xHCI host controller. Right click the node, and choose **Properties**. If there is a **Power Management** tab, open the tab, and clear the **Allow the computer to turn off this device to save power** check box.

When you have finished using the xHCI host controller for debugging, enable selective suspend for the xHCI host controller.

## Setting Up Kernel-Mode Debugging over a USB 2.0 Cable Manually

Debugging Tools for Windows supports kernel debugging over a USB 2.0 cable. This topic describes how to set up USB 2.0 debugging manually.

As an alternative to setting up USB 2.0 debugging manually, you can do the setup using Microsoft Visual Studio. For more information, see [Setting Up Kernel-Mode Debugging over a USB 2.0 Cable in Visual Studio](#).

The computer that runs the debugger is called the *host computer*, and the computer being debugged is called the *target computer*.

Debugging over a USB 2.0 cable requires the following hardware:

- A USB 2.0 debug cable. This cable is not a standard USB 2.0 cable because it has an extra hardware component that makes it compatible with the USB2 Debug Device Functional Specification. You can find these cables with an Internet search for the term *USB 2.0 debug cable*.
- On the host computer, an EHCI (USB 2.0) host controller
- On the target computer, an EHCI (USB 2.0) host controller that supports debugging

## Setting Up the Target Computer

1. On the target computer, launch the UsbView tool. The UsbView tool is included in Debugging Tools for Windows.
2. In UsbView, locate all of the host controllers that are compatible with the EHCI specification. For example, you could look for controllers that are listed as Enhanced.
3. In UsbView, expand the nodes of the EHCI host controllers. Look for an indication that a host controller supports debugging, and look for the number of the debug port. For example, UsbView displays this output for an EHCI host controller that supports debugging on port 1.

```
XXX XXX XXX USB2 Enhanced Host Controller - 293A
...
Debug Port Number: 1
Bus.Device.Function (in decimal): 0.29.7
```

**Note** Many EHCI host controllers support debugging on port 1, but some EHCI host controllers support debugging on port 2.

4. Make a note of the bus, device, and function numbers for the EHCI controller that you intend to use for debugging. UsbView displays these number. In the preceding example, the bus number is 0, the device number is 29, and the function number is 7.
5. After you have identified the EHCI controller and the port number that supports debugging, the next step is to locate the physical USB connector that is associated with the correct port number. To find the physical connector, plug any USB 2.0 device into any USB connector on the target computer. Refresh UsbView to see where your device is located. If UsbView shows your device connected to the EHCI host controller and port that you identified as the debug port, then you have found a physical USB connector that you can use for debugging. It could be that there is no external physical USB connector that is associated with a debug port on an EHCI controller. In that case, you can look for a physical USB connector inside the computer. Perform the same steps to determine whether the internal USB connector is suitable for kernel debugging. If you cannot find a physical USB connector (either external or internal) that is associated with a debug port, then you cannot use the computer as a target for debugging over a USB 2.0 cable.

**Note** See [this remark](#) for an exception.

6. On the target computer, open a Command Prompt window as Administrator, and enter these commands:

- **bcdeedit /debug on**
- **bcdeedit /dbgsettings usb targetname:TargetName**

where *TargetName* is a name that you create for the target computer. Note that *TargetName* does not have to be the official name of the target computer; it can be any string that you create as long as it meets these restrictions:

- The maximum length of the string is 24 characters.
- The only characters in the string are the hyphen (-), the underscore(\_), the digits 0 through 9, and the letters A through Z (upper or lower case).

7. If there is more than one USB host controller on the target computer, enter this command:

Windows 7 or later

```
bcdeedit /set "{dbgsettings}" busparams b.d.f
```

where *b*, *d*, and *f* are the bus, device, and function numbers for the host controller. The bus, device, and function numbers must be in decimal format (for example, **busparams 0.29.7**).

Windows Vista

```
bededit /set "{current}" loadoptions busparams=f.d.f
```

where *b*, *d*, and *f* are the bus, device, and function numbers for the host controller. The bus, device, and function numbers must be in hexadecimal format (for example, **busparams=0.1D.7**).

8. Reboot the target computer.

## Setting Up the Host Computer

1. Verify that the host computer is not configured to be the target of USB debugging. (If necessary, open a Command Prompt window as Administrator, enter **bcdeedit /debug off**, and reboot.)
2. On the host computer, use UsbView to find the EHCI host controllers and ports that support debugging. If possible, plug one end of the USB 2.0 debug cable into an EHCI port (on the host computer) that does not support debugging. Otherwise, plug the cable into any EHCI port on the host computer.
3. Plug the other end of the USB 2.0 debug cable into the connector that you identified previously on the target computer.

## Starting a Debugging Session for the First Time

1. Determine the bitness (32-bit or 64-bit) of Windows running on the host computer.
2. On the host computer, open a version of WinDbg (as Administrator) that matches the bitness of Windows running on the host computer. For example, if the host computer is running a 64-bit version of Windows, open the 64-bit version of WinDbg as Administrator.
3. On the **File** menu, choose **Kernel Debug**. In the Kernel Debugging dialog box, open the **USB** tab. Enter the target name that you created when you set up the target computer. Click **OK**.

At this point, the USB debug driver gets installed on the host computer. This is why it is important to match the bitness of WinDbg to the bitness of Windows. After the USB

debug driver is installed, you can use either the 32-bit or 64-bit version of WinDbg for subsequent debugging sessions.

**Note** The USB 2.0 debug cable is actually two cables with a dongle in the middle. The direction of the dongle is important; one side powers the device, and the other side does not. If USB debugging doesn't work, try swapping the direction of the dongle. That is, unplug both cables from the dongle, and swap the sides that the cables are connected to.

## Starting a Debugging Session

### Using WinDbg

On the host computer, open WinDbg. On the **File** menu, choose **Kernel Debug**. In the Kernel Debugging dialog box, open the **USB** tab. Enter the target name that you created when you set up the target computer. Click **OK**.

You can also start a session with WinDbg by entering the following command in a Command Prompt window, where *TargetName* is the target name you created when you set up the target computer:

```
windbg /k usb:targetname=TargetName
```

### Using KD

On the host computer, open a Command Prompt window and enter the following command, where *TargetName* is the target name you created when you set up the target computer:

```
kd /k usb:targetname=TargetName
```

## What if USBView shows a debug-capable port, but does not show the port mapped to any physical connector?

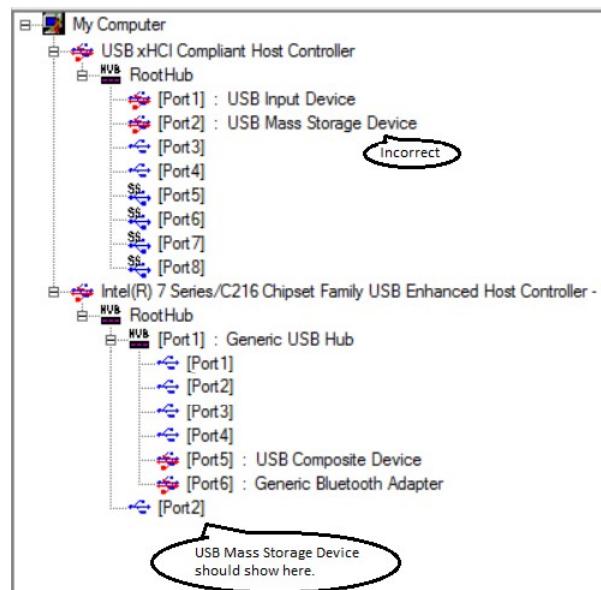

On some computers, USBView shows a debug-capable port, but does not show the port mapped to any physical USB connector. For example, USBView might show port 2 as the debug port number for an eHCI controller.

```
... USB Enhanced Host Controller ...
...
Debug Port Number: 2
Bus.Device.Function (in decimal): 0.29.0
```

Also, when you use USBView to look at the individual port, it is listed as debug-capable.

```
[Port 2]
Is Port User Connectable: Yes
Is Port Debug Capable: Yes
...
Protocols Supported
 USB 1.1 yes
 USB 2.0 yes
 USB 3.0 no
```

But when you plug in a USB 2.0 device (like a flash drive) to all the USB connectors on the computer, USBView never show your device connected to the debug-capable port (port 2 in this example). USBView might show the external connector mapped to a port of an xHCI controller when in fact the external connector is mapped to the debug-capable port of the eHCI controller.

In a case like this, you might still be able to establish kernel-mode debugging over a USB 2.0 cable. In the example given here, you would plug your USB 2.0 debug cable into the connector that shows as being mapped to Port 2 of the xHCI controller. Then you would set your bus parameters to the bus, device, and function numbers of the eHCI controller (in this example, 0.29.0).

```
bcedit /set "dbgsettings" busparams 0.29.0
```

## Additional Support

For troubleshooting tips and detailed instructions on setting up kernel debugging over USB, see [Setting Up Kernel Debugging with USB 2.0](#) in MSDN Blogs.

# Setting Up Kernel-Mode Debugging over a Serial Cable Manually

Debugging Tools for Windows supports kernel debugging over a null-modem cable. Null-modem cables are serial cables that have been configured to send data between two serial ports. They are available at most computer stores. Do not confuse null-modem cables with standard serial cables. Standard serial cables do not connect serial ports to each other. For information about how null-modem cables are wired, see [Null-Modem Cable Wiring](#).

This topic describes how to set up serial debugging manually. As an alternative to setting up serial debugging manually, you can do the setup using Microsoft Visual Studio. For more information, see [Setting Up Kernel-Mode Debugging over a Serial Cable in Visual Studio](#).

The computer that runs the debugger is called the *host computer*, and the computer being debugged is called the *target computer*.

## Setting Up the Target Computer

1. On the target computer, open a Command Prompt window as Administrator, and enter the following commands, where *n* is the number of the COM port used for debugging on the target computer, and *rate* is the baud rate used for debugging:

```
bcedit /debug on
bcedit /dbgsettings serial debugport:n baudrate:rate
```

**Note** The baud rate must be the same on the host computer and target computer. The recommended rate is 115200.

2. Reboot the target computer.

## Starting the Debugging Session

Connect the null-modem cable to the COM ports that you have chosen for debugging on the host and target computers.

### Using WinDbg

On the host computer, open WinDbg. On the **File** menu, choose **Kernel Debug**. In the Kernel Debugging dialog box, open the **COM** tab. In the **Baud rate** box, enter the rate you have chosen for debugging. In the **Port** box, enter COM*n* where *n* is the COM port number you have chosen for debugging on the host computer. Click **OK**.

You can also start a session with WinDbg by entering the following command in a Command Prompt window; *n* is the number of the COM port used for debugging on the host computer, and *rate* is the baud rate used for debugging:

```
windbg -k com:port=COMn,baud=rate
```

### Using KD

On the host computer, open a Command Prompt window, and enter the following command, where *n* is the number of the COM port used for debugging on the host computer, and *rate* is the baud rate used for debugging:

```
kd -k com:port=COMn,baud=rate
```

## Using Environment Variables

On the host computer, you can use environment variables to specify the COM port and the baud rate. Then you do not have to specify the port and baud rate each time you start a debugging session. To use environment variables to specify the COM port and baud rate, open a Command Prompt window and enter the following commands, where *n* is the number of the COM port used for debugging on the host computer, and *rate* is the baud rate used for debugging:

- `set _NT_DEBUG_PORT=COMn`
- `set _NT_DEBUG_BAUD_RATE=rate`

To start a debugging session, open a Command Prompt window, and enter one of the following commands:

- `kd`
- `windbg`

## Troubleshooting Tips for Debugging over a Serial Cable

### Specify correct COM port on both host and target

Determine the numbers of the COM ports you are using for debugging on the host and target computers. For example, suppose you have your null-modem cable connected to COM1 on the host computer and COM2 on the target computer.

On the target computer, open a Command Prompt window as Administrator, and enter **bcedit /dbgsettings**. If you are using COM2 on the target computer, the output of **bcedit** should show `debugport 2`.

On the host computer, specify the correct COM port when you start the debugger or when you set environment variables. If you are using COM1 on the host computer, use one of the following methods to specify the COM port.

- In WinDbg, in the Kernel Debugging dialog box, enter COM1 in the **Port** box.
- `windbg -k com:port=COM1, ...`
- `kd -k com:port=COM1, ...`
- `set _NT_DEBUG_PORT=COM1`

#### Baud rate must be the same on host and target

The baud rate used for debugging over a serial cable must be set to the same value on the host and target computers. For example, suppose you have chosen a baud rate of 115200.

On the target computer, open a Command Prompt window as Administrator, and enter **bcedit /dbgsettings**. The output of **bcedit** should show `baudrate 115200`.

On the host computer, specify the correct baud rate when you start the debugger or when you set environment variables. Use one of the following methods to specify a baud rate of 115200.

- In WinDbg, in the Kernel Debugging dialog box, enter 115200 in the **Baud rate** box.
- `windbg -k ..., baud=115200`
- `kd -k ..., baud=115200`
- `set _NT_DEBUG_BAUD_RATE=115200`

### Null Modem Cable Wiring

The following tables show how null-modem cables are wired.

#### 9-pin connector

| Connector 1 | Connector 2 | Signals        |
|-------------|-------------|----------------|
| 2           | 3           | Tx - Rx        |
| 3           | 2           | Rx - Tx        |
| 7           | 8           | RTS - CTS      |
| 8           | 7           | CTS - RTS      |
| 4           | 1+6         | DTR - (CD+DSR) |
| 1+6         | 4           | (CD+DSR) - DTR |
| 5           | 5           | Signal ground  |

#### 25-pin connector

| Connector 1 | Connector 2 | Signals       |
|-------------|-------------|---------------|
| 2           | 3           | Tx - Rx       |
| 3           | 2           | Rx - Tx       |
| 4           | 5           | RTS - CTS     |
| 5           | 4           | CTS - RTS     |
| 6           | 20          | DSR - DTR     |
| 20          | 6           | DTR - DSR     |
| 7           | 7           | Signal ground |

#### Signal Abbreviations

| Abbreviation | Signal              |
|--------------|---------------------|
| Tx           | Transmit data       |
| Rx           | Receive data        |
| RTS          | Request to send     |
| CTS          | Clear to send       |
| DTR          | Data terminal ready |
| DSR          | Data set ready      |
| CD           | Carrier detect      |

### Additional Information

For complete documentation of the **bcedit** command, see Boot Options for Driver Testing and Debugging in the Windows Driver Kit (WDK) documentation.

# Setting Up Kernel-Mode Debugging using Serial over USB Manually

The [Sharks Cove development board](#) supports serial debugging over a USB cable.

This topic describes how to set up serial debugging over a USB cable manually. As an alternative to setting up manually, you can do the setup using Microsoft Visual Studio. For more information, see [Setting Up Kernel-Mode Debugging using Serial over USB in Visual Studio](#).

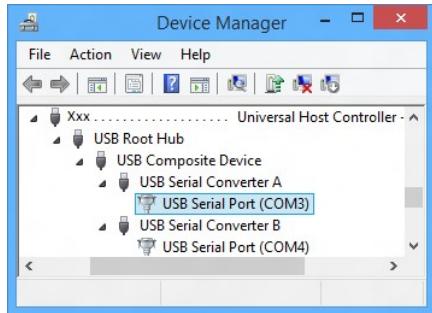

The computer that runs the debugger is called the *host computer*, and the computer being debugged is called the *target computer*. In this topic, the Sharks Cove board is the target computer.

## Setting up a Host Computer for debugging the Sharks Cove board

1. On the host computer, open Device Manager. On the View menu, choose **Devices by Type**.
2. On the Sharks Cove board, locate the debug connector. This is the micro USB connector shown in the following picture.

3. Use a USB 2.0 cable to connect the host computer to the debug connector on the Sharks cove board.
4. On the host computer, in Device Manager, two COM ports will get enumerated. Select the lowest numbered COM port. On the View menu, choose **Devices by Connection**. Verify that the COM port is listed under one of the USB host controllers.

Make a note of the COM port number. This is the lowest COM port number that shows under the USB host controller node. For example, in the preceding screen shot, the lowest COM port number under the USB host controller is COM3. You will need this COM port number later when you start a debugging session. If the driver is not already installed for the COM port, right click the COM port node, and choose **Update Driver**. Then select **Search automatically for updated driver software**. You will need an internet connection for this.

## Setting Up the Sharks Cove Board as the Target Computer

1. On the target computer (Sharks Cove board), open a Command Prompt window as Administrator, and enter these commands:

```
bcedit /debug on
bcedit /dbgsettings serial debugport:1 baudrate:115200
```

2. Reboot the target computer.

## Starting the Debugging Session

### Using WinDbg

On the host computer, open WinDbg. On the File menu, choose **Kernel Debug**. In the Kernel Debugging dialog box, open the **COM** tab. In the **Baud rate** box, enter 115200. In the **Port** box, enter COMn where n is the COM port number you noted previously. Click **OK**.

You can also start a session with WinDbg by entering the following command in a Command Prompt window; *n* is the number of the COM port that you noted on the host computer:

```
windbg -k com:port=COMn,baud=115200
```

## Using KD

On the host computer, open a Command Prompt window, and enter the following command, where *n* is the COM port number you noted previously:

```
kd -k com:port=COMn,baud=115200
```

## Using Environment Variables

On the host computer, you can use environment variables to specify the COM port and the baud rate. Then you do not have to specify the port and baud rate each time you start a debugging session. To use environment variables to specify the COM port and baud rate, open a Command Prompt window and enter the following commands, where *n* is the number COM port number you noted previously:

- `set _NT_DEBUG_PORT=COMn`
- `set _NT_DEBUG_BAUD_RATE=115200`

To start a debugging session, open a Command Prompt window, and enter one of the following commands:

- `kd`
- `windbg`

## Troubleshooting Tips for Serial Debugging over a USB Cable

### Specify correct COM port on both host and target

On the target computer (Sharks Cove board), verify that you are using COM1 for debugging. Open a Command Prompt window as Administrator, and enter `bcdedit /dbgsettings`. The output of `bcdedit` should show `debugport 1`.

On the host computer, specify the correct COM port when you start the debugger or when you set environment variables. This is the lowest numbered COM port that was enumerated under the USB host controller in Device Manager. For example, if COM3 is the desired port, use one of the following methods to specify the COM port.

- In WinDbg, in the Kernel Debugging dialog box, enter COM3 in the **Port** box.
- `windbg -k com:port=COM3, ..`
- `kd -k com:port=COM3, ..`
- `set _NT_DEBUG_PORT=COM3`

### Baud rate must be the same on host and target

The baud rate must be 115200 on both the host and target computers.

On the target computer (Sharks Cove board), open a Command Prompt window as Administrator, and enter `bcdedit /dbgsettings`. The output of `bcdedit` should show `baudrate 115200`.

On the host computer, specify the correct baud rate when you start the debugger or when you set environment variables. Use one of the following methods to specify a baud rate of 115200.

- In WinDbg, in the Kernel Debugging dialog box, enter 115200 in the **Baud rate** box.
- `windbg -k ..., baud=115200`
- `kd -k ..., baud=115200`
- `set _NT_DEBUG_BAUD_RATE=115200`

## Additional Information

For complete documentation of the `bcdedit` command, see Boot Options for Driver Testing and Debugging in the Windows Driver Kit (WDK) documentation.

## Setting Up Kernel-Mode Debugging of a Virtual Machine Manually

Debugging Tools for Windows supports kernel debugging of a virtual machine. The virtual machine can be located on the same physical computer as the debugger or on a different computer that is connected to the same network. This topic describes how to set up debugging of a virtual machine manually.

As an alternative to setting up debugging of a virtual machine manually, you can do the setup using Microsoft Visual Studio. For more information, see [Setting Up Kernel-Mode Debugging of a Virtual Machine in Visual Studio](#).

The computer that runs the debugger is called the *host computer*, and the virtual machine being debugged is called the *target virtual machine*.

## Setting Up the Target Virtual Machine

1. In the virtual machine, in an elevated Command Prompt window, enter the following commands.

```
bcedit /debug on
bcedit /dbgsettings serial debugport:n baudrate:115200
```

where *n* is the number of a COM port on the virtual machine.

**Note** By default, COM ports are not presented in generation 2 virtual machines. For information about how to create a COM port, see [Generation 2 Virtual Machines](#).

2. Reboot the virtual machine.
3. In the virtual machine, configure the COM port to map to a named pipe. The debugger will connect through this pipe. For more information about how to create this pipe, see your virtual machine's documentation.

## Starting the Debugging Session Using WinDbg

On the host computer, open WinDbg. On the **File** menu, choose **Kernel Debug**. In the Kernel Debugging dialog box, open the **COM** tab. Check the **Pipe** box, and check the **Reconnect** box. For **Baud Rate**, enter 115200. For **Resets**, enter 0.

If the debugger is running on the same computer as the virtual machine, enter the following for **Port**.

`\.\pipe\PipeName`.

If the debugger is running on a different computer from the virtual machine, enter the following for **Port**.

`\VMHost\pipe\PipeName`

Click **OK**.

You can also start WinDbg at the command line. If the debugger is running on the same physical computer as the virtual machine, enter the following command in a Command Prompt window.

```
windbg -k com:pipe,port=\.\pipe\PipeName, resets=0,reconnect
```

If the debugger is running on a different physical computer from the virtual machine, enter the following command in a Command Prompt window.

```
windbg -k com:pipe,port=\VMHost\pipe\PipeName, resets=0,reconnect
```

## Starting the Debugging Session Using KD

To debug a virtual machine that is running on the same physical computer as the debugger, enter the following command in a Command Prompt window.

```
kd -k com:pipe,port=\.\pipe\PipeName, resets=0,reconnect
```

To debug a virtual machine that is running on a different physical computer from the debugger, enter the following command in a Command Prompt window.

```
kd -k com:pipe,port=\VMHost\pipe\PipeName, resets=0,reconnect
```

## Parameters

*VMHost*

Specifies the name of the computer that the virtual machine is running on.

*PipeName*

Specifies the name of the pipe that you created on the virtual machine.

*resets=0*

Specifies that an unlimited number of reset packets can be sent to the target when the host and target are synchronizing. Use the **resets=0** parameter for Microsoft Virtual PC and other virtual machines whose pipes drop excess bytes. Do not use this parameter for VMware or other virtual machines whose pipes do not drop all excess bytes.

*reconnect*

Causes the debugger to automatically disconnect and reconnect the pipe if a read/write failure occurs. Additionally, if the debugger does not find the named pipe when the debugger is started, the **reconnect** parameter causes the debugger to wait for a pipe that is named *PipeName* to appear. Use **reconnect** for Virtual PC and other virtual machines that destroy and re-create their pipes during a computer restart. Do not use this parameter for VMware or other virtual machines that preserve their pipes during a computer restart.

For more information about additional command-line options, see [KD Command-Line Options](#) or [WinDbg Command-Line Options](#).

## Generation 2 Virtual Machines

By default, COM ports are not presented in generation 2 virtual machines. You can add COM ports through PowerShell or WMI. For the COM ports to be displayed in the Hyper-V Manager console, they must be created with a path.

To enable kernel debugging using a COM port on a generation 2 virtual machine, follow these steps:

1. Disable Secure Boot by entering this PowerShell command:

```
Set-VMFirmware -Vmname VmName -EnableSecureBoot Off
```

where *VmName* is the name of your virtual machine.

2. Add a COM port to the virtual machine by entering this PowerShell command:

```
Set-VMComPort -VMName VmName 1 \\.\pipe\PipeName
```

For example, the following command configures the first COM port on virtual machine TestVM to connect to named pipe TestPipe on the local computer.

```
Set-VMComPort -VMName TestVM 1 \\.\pipe\TestPipe
```

For more information, see [Generation 2 Virtual Machine Overview](#).

## Remarks

If the target computer has stopped responding, the target computer is still stopped because of an earlier kernel debugging action, or you used the **-b** [command-line option](#), the debugger breaks into the target computer immediately.

Otherwise, the target computer continues running until the debugger orders it to break.

**Note** If you restart the virtual machine by using the VMWare facilities (for example, the reset button), exit WinDbg, and then restart WinDbg to continue debugging.

During virtual machine debugging, VMWare often consumes 100% of the CPU.

## Setting Up Local Kernel Debugging of a Single Computer Manually

Debugging Tools for Windows supports *local kernel debugging*. This is kernel-mode debugging on a single computer. In other words, the debugger runs on the same computer that is being debugged. With local debugging you can examine state, but not break into kernel mode processes that would cause the OS to stop running.

The *local* `bcedit` option is available in Windows 8.0 and Windows Server 2012 and later.

### Setting Up Local Kernel-Mode Debugging

1. Open a Command Prompt window as Administrator. Enter `bcedit /debug on`
2. If the computer is not already configured as the target of a debug transport, enter `bcedit /dbgsettings local`
3. Reboot the computer.

### Starting the Debugging Session

#### Using WinDbg

Open WinDbg as Administrator. On the **File** menu, choose **Kernel Debug**. In the Kernel Debugging dialog box, open the **Local** tab. Click **OK**.

You can also start a session with WinDbg by opening a Command Prompt window as Administrator and entering the following command:

```
windbg -kl
```

#### Using KD

Open a Command Prompt window as Administrator, and enter the following command:

```
kd -kl
```

## Supported Ethernet NICs for Network Kernel Debugging in Windows 8.1

You can do kernel debugging over an Ethernet network cable when the target computer is running Windows 8.1. The target computer must have a supported network interface card (NIC) or network adapter.

During kernel debugging, the computer that runs the debugger is called the *host computer*, and the computer being debugged is called the *target computer*. To do [kernel debugging over a network cable](#), the target computer must have a supported network adapter. When the target computer is running Windows 8.1, the network adapters listed here are supported for kernel debugging.

**Note** Support for kernel debugging over selected 10 gigabit network adapters is a new feature in Windows 8.1. Debugging over 10 gigabit network adapters is not supported in Windows 8. For a list of network adapters supported by Windows 8 for kernel debugging, see [Supported Ethernet NICs for Network Kernel Debugging in Windows 8](#).

## System Requirements

Kernel debugging through Ethernet NICs requires certain low-level platform support. Windows requires that these NICs be attached via PCI/PCIe for this debugging solution. In most cases, simply plugging in one of these supported NICs will allow a robust kernel debugging experience. However, there may be cases where BIOS configuration details hinder the Windows debug path. The following platform requirement should be considered:

- System firmware should discover and configure the NIC device such that its resources do not conflict with any other devices that have been BIOS-configured.

## Finding the vendor ID and device ID

First find the vendor ID and device ID of the network adapter on your target computer.

- On the target computer, open Device Manager (enter **devmgmt** in a Command Prompt window).
- In Device Manager, locate the network adapter that you want to use for debugging.
- Right click the network adapter node, and choose **Properties**.
- In the **Details** tab, under **Property**, select **Hardware IDs**.

The vendor and device IDs are shown as VEN\_VendorID and DEV\_DeviceID. For example, if you see PCI\VEN\_8086&DEV\_104B, the vendor ID is 8086, and the device ID is 104B.

## Vendor ID 8086, Intel Corporation

For vendor ID 8086, these device IDs are supported:

## Supported Ethernet NICs for Network Kernel Debugging in Windows 8

You can do kernel debugging over an Ethernet network cable when the target computer is running Windows 8. The target computer must have a supported network interface card (NIC) or network adapter.

During kernel debugging, the computer that runs the debugger is called the *host computer*, and the computer being debugged is called the *target computer*. To do [kernel debugging over a network cable](#), the target computer must have a supported network adapter. When the target computer is running Windows 8, the network adapters listed here are supported for kernel debugging.

**Note** For a list of network adapters supported by Windows 8.1 for kernel debugging, see [Supported Ethernet NICs for Network Kernel Debugging in Windows 8.1](#).

## System Requirements

Kernel debugging through Ethernet NICs requires certain low-level platform support. Windows requires that these NICs be attached via PCI/PCIe for this debugging solution. In most cases, simply plugging in one of these supported NICs will allow a robust kernel debugging experience. However, there may be cases where BIOS configuration

details hinder the Windows debug path. The following set of platform requirements should be considered:

- System firmware should discover and configure the NIC device such that its resources do not conflict with any other devices that have been BIOS-configured.
- System firmware should place the NIC's resources under address windows that are not marked prefetchable.

## Finding the vendor ID and device ID

First find the vendor ID and device ID of the network adapter on your target computer.

- On the target computer, open Device Manager (enter **devmgmt** in a Command Prompt window).
- In Device Manager, locate the network adapter that you want to use for debugging.
- Right click the network adapter node, and choose **Properties**.
- In the **Details** tab, under **Property**, select **Hardware IDs**.

The vendor and device IDs are shown as *VEN\_VendorID* and *DEV\_DeviceID*. For example, if you see PCI\VEN\_8086&DEV\_104B, the vendor ID is 8086, and the device ID is 104B.

## Setting Up User-Mode Debugging in Visual Studio

There are two user-mode debuggers available in the Microsoft Visual Studio environment. One is the Windows User-Mode Debugger, which is included in Debugging Tools for Windows. The other is the Visual Studio Debugger, which is part of the Visual Studio product. This topic describes how to get set up to use the Windows User-Mode Debugger from within the Visual Studio environment.

### Debugging a User-Mode Process on the Local Computer

No special setup is required for debugging a user-mode process on the local computer. For information about attaching to a process or launching a process under the debugger, see [Debugging a User-Mode Process Using Visual Studio](#).

### Debugging a User-Mode Process on a Target Computer

In some cases, two computers are used for debugging. The debugger runs on the *host computer*, and the code that is being debugged runs on the *target computer*. In Visual Studio (running on the host computer), you can use the Windows User-Mode Debugger to attach to a user-mode process on a target computer.

On the target computer, go to **Control Panel>Network and Internet>Network and Sharing Center>Advanced sharing settings**. Under **Guest or Public**, select **Turn on network discovery** and **Turn on file and printer sharing**.

You can do the rest of the configuration from the host computer:

1. On the host computer, in Visual Studio, on the **Tools** menu, choose **Attach to Process**.
2. For **Transport**, choose **Windows User Mode Debugger**.
3. To the right of the **Qualifier** box, click the **Browse** button.
4. Click the **Add** button.
5. Enter the name of the target computer.
6. To the right of **Configure Target Computer**, click the **Configure** button. The **Configure Target Computer** dialog box opens and displays the configuration progress.
7. When the configuration is complete, in the **Configure Computers** dialog box, click **OK**.

## Setting Up Network Debugging of a Virtual Machine Host

If your target computer is a virtual machine host, you can set up network debugging and still have network access for the virtual machines.

Suppose you want to set up network debugging in the following situation.

- The target computer has a single network interface card.
- You intend to install the Hyper-V role on the target computer.
- You intend to create one or more virtual machines on the target computer.

The best approach is to set up network debugging on the target computer before you install the Hyper-V role. Then the virtual machines will have access to the network.

If you decide to set up network debugging after the Hyper-V role has been installed on the target computer, you must change the network settings for your virtual machines to bridge them to the Microsoft Kernel Network Debug Adapter. Otherwise, the virtual machines will not have access to the network.

## Configuring tools.ini

The file tools.ini contains information to initialize the command-line debuggers. On startup, the debugger searches for the appropriate section header in the tools.ini file and extracts initialization information from the entries under the header. Each command-line debugger has its own section header - [CDB], [NTSD], and [KD]. The environment variable INIT must point to the directory containing the tools.ini file.

WinDbg does not use the tools.ini file. Instead, WinDbg saves initialization settings in [workspaces](#).

The tools.ini entries are shown in the following table.

Keywords must be separated from the values by white space or a colon. Keywords are not case-sensitive.

For **TRUE** or **FALSE** values, "FALSE" is the only false value. Anything else is **TRUE**.

| Entry                                        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| <b>\$u0: value ... \$u9:</b><br><i>value</i> | Assign values to fixed-name aliases. You can specify numeric values <i>n</i> or <i>0xn</i> or any other string. See <a href="#">Using Aliases</a> for details. No command-line equivalent.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>DebugChildren:</b><br><i>flag</i>         | <b>TRUE</b> or <b>FALSE</b> . If <b>TRUE</b> , CDB debugs the specified application as well as any child processes that it might spawn. Command-line equivalent is <b>-o</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>DebugOutput:</b><br><i>flag</i>           | <b>TRUE</b> or <b>FALSE</b> . If <b>TRUE</b> , CDB sends output and receives input through a terminal. If <b>FALSE</b> , output goes to the user screen. The command-line option <b>-d</b> is similar but not identical.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>IniFile:</b><br><i>file</i>               | Specifies the name of the script file that CDB or KD takes commands from at startup. The default is the ntsd.ini file in the current directory. Command-line equivalent is <b>-cf</b> . For details, see <a href="#">Using Script Files</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>LazyLoad:</b><br><i>flag</i>              | <b>TRUE</b> or <b>FALSE</b> . If <b>TRUE</b> , CDB performs lazy symbol loading; that is, symbols are not loaded until required. Command-line equivalent is <b>-s</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>SetDll:</b><br><i>filename</i>            | For details, and other methods of setting this option, see <a href="#">Deferred Symbol Loading</a> .<br>Set extension DLL. The .dll filename extension should be omitted. Default is userexts.dll. Command-line equivalent is <b>-a</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>StopFirst:</b><br><i>flag</i>             | <b>TRUE</b> or <b>FALSE</b> . If <b>true</b> , CDB stops on the breakpoint at the end of the image-loading process. Command-line equivalent is <b>-g</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>StopOnProcessExit:</b><br><i>flag</i>     | <b>TRUE</b> or <b>FALSE</b> . If <b>TRUE</b> , CDB stops when it receives a process termination notification. Command-line equivalent is <b>-G</b> .<br>Sets the debugger response and the handling status for the specified exception or event.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|                                              | Exceptions and events may be specified in the following ways:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| <b>srcopt:</b><br><i>options</i>             | Sets the source line options that control source display and program stepping options. For more information see <a href="#">I+ I- (Set Source Options)</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>srcpath:</b><br><i>directory</i>          | Sets the source file search path. For more information see <a href="#">.srcpath, .lsrcpath (Set Source Path)</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>enable_unicode:</b><br><i>flag</i>        | <b>TRUE</b> or <b>FALSE</b> . The <b>enable_unicode</b> flag specifies whether the debugger displays USHORT pointers and arrays as Unicode strings.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>force radix_output:</b><br><i>flag</i>    | <b>TRUE</b> or <b>FALSE</b> . The <b>force radix_output</b> flag specifies whether integers are displayed in decimal format or in the default radix.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>col_mode:</b><br><i>flag</i>              | <b>TRUE</b> or <b>FALSE</b> . The <b>col_mode</b> flag controls the color mode setting. When color mode is enabled the debugger can produce colored output. By default, most colors are not set and instead default to the current console colors.<br>The <i>name</i> indicates the element that you are coloring. The <i>colspec</i> is a three-letter RGB indicator of the form [rR-][gG-][bB-]. A lower-case letter indicates darker, an upper-case letter indicates brighter and a dash indicates no color component contribution. Due to console color limitations, bright is not actually per-component, but applies to all components if any request bright. In other words, rgB is the same as RGB. For this reason, it is recommended that all caps be used if any caps are going to be used. |
| <b>col:</b><br><i>name colspec</i>           | Example usage:<br><br>col: emphfg R--                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

A sample [NTSD] section in the tools.ini file follows:

```
[NTSD]
sxe: 3c
sxe: cc
$u0: VeryLongName
VerboseOutput:true
```

## Using KDbgCtrl

The KDbgCtrl (Kernel Debugging Control, kdbgctrl.exe) tool can be used to control the kernel debugging connection from the target computer.

To use this tool, your target computer must be running Windows Server 2003 or a later version of Windows.

KDbgCtrl can control five different settings: Full Kernel Debugging, Automatic Kernel Debugging, User-Mode Error Handling, Blocking of Kernel Debugging, and the size of the DbgPrint buffer.

To use KDbgCtrl, you must have already enabled kernel debugging in the boot settings of the target computer before the last boot. KDbgCtrl cannot be used to enable kernel debugging if this was not done. See [Boot Parameters to Enable Debugging](#) for details on these boot settings.

### Full Kernel Debugging

When Full Kernel Debugging is enabled, a kernel debugger running on the host computer can break into the target computer. The target computer will break into the kernel debugger if a kernel-mode exception is hit. Messages from the target to the host, such as **DbgPrint** output, symbol load messages, and redirected user-mode debuggers, are also allowed.

If this setting is disabled, all signals from the host computer will be ignored by the target.

Full Kernel Debugging is enabled by default. To check the current setting value, use **kdbgctrl -c**. To disable this setting, use **kdbgctrl -d**. To enable this setting, use **kdbgctrl -e**.

If you wish to check the current setting and use it to control execution within a batch file, you can use the **kdbgctrl -ex** command. For details on this command, see [KDbgCtrl Command-Line Options](#).

### Automatic Kernel Debugging

If Full Kernel Debugging is enabled, the current setting for Automatic Kernel Debugging is immaterial -- all communication is permitted.

When Full Kernel Debugging is disabled and Automatic Kernel Debugging is enabled, only the target computer can initiate a debugging connection.

In this case, only a kernel-mode exception, breakpoint, or other kernel-mode event will cause a connection to be established. The connection will not be established for **DbgPrint** output, symbol load messages, redirected user-mode debugger input and output, or other similar messages -- these will be stored in the DbgPrint buffer instead of being sent to the kernel debugger.

If an exception or event causes the target to break into the kernel debugger, then Full Kernel Debugging will be automatically turned on, just as if you had executed **kdbgctrl -e**.

Automatic Kernel Debugging is disabled by default (although this is immaterial unless Full Kernel Debugging is disabled as well). To check the current setting value, use **kdbgctrl -ca**. To disable this setting, use **kdbgctrl -da**. To enable this setting, use **kdbgctrl -ea**.

### User-Mode Error Handling

When User-Mode Error Handling is enabled, some user-mode events will cause the target computer to break into the kernel debugger.

Specifically, all **int 3** interrupts -- such as breakpoints inserted into the code by a debugger or calls to **DbgBreakPoint** -- will cause a break into the kernel debugger. However, standard exceptions -- such as access violations and division by zero -- will usually not be sent to the kernel debugger.

If a user-mode debugger is already attached to the process, this debugger will capture all user-mode errors, and the kernel debugger will not be alerted. For the precedence ranking of the various user-mode error handlers, see [Enabling Postmortem Debugging](#).

For User-Mode Error Handling to function, either Full Kernel Debugging or Automatic Kernel Debugging must be enabled as well.

User-Mode Error Handling is enabled by default. To check the current setting value, use **kdbgctrl -cu**. To disable this setting, use **kdbgctrl -du**. To enable this setting, use **kdbgctrl -eu**.

### Blocking Kernel Debugging

In some cases you might want to set up the target computer for kernel debugging, but wait to enable kernel debugging until after the target computer is started. You can do that by blocking kernel debugging.

To block kernel debugging, set up the target computer by using commands similar to the following:

```
bcdedit /debug on
bcdedit /dbgsettings 1394 channel:32 /start DISABLE /noumex
```

When you restart the target computer, it will be prepared for kernel debugging, but kernel debugging and User-Mode Error Handling will be disabled. At that point, a host computer will not be able to attach to the target computer, bug checks will not be caught by the kernel debugger, and user-mode exceptions will not cause a break in to the kernel debugger.

When you are ready, you can enable kernel debugging (without restarting the target computer) by entering the following commands.

```
kdbgctrl -db
kdbgctrl -e
```

Later, you can disable kernel debugging by entering the following commands.

```
kdbgctrl -d
kdbgctrl -eb
```

You can use **kdbgctrl -cb** to check whether kernel debugging is blocked.

### The DbgPrint Buffer Size

The DbgPrint buffer stores messages that the target computer has sent to the kernel debugger.

If Full Kernel Debugging is enabled, these messages will automatically appear in the kernel debugger. But if this option is disabled, these messages will be stored in the

buffer. At a later point in time, you can enable kernel debugging, connect to a kernel debugger, and use the [!dbgprint](#) extension to see the contents of this buffer. For more information about this buffer, see [The DbgPrint Buffer](#).

The default size of the DbgPrint buffer is 4 KB on a free build of Windows, and 32 KB on a checked build of Windows. To determine the current buffer size, use `kdbgctrl -cdb`. To change the buffer size, use `kdbgctrl -sdbSize`, where *Size* specifies the new buffer size. For syntax details, see [KDbgCtrl Command-Line Options](#).

## Examples

To display all the current settings, use the following command:

```
kdbgctrl -c -ca -cu -cb -cdb
```

To restore the default settings, use the following command:

```
kdbgctrl -e -da -eu -db -sdb 0x1000
```

To lock out the host computer so that it only is contacted on exceptions, use the following command:

```
kdbgctrl -d -ea -eu
```

To disable all kernel debugging, use the following command:

```
kdbgctrl -d -da
```

If you are disabling all kernel debugging, you may also wish to increase the size of the DbgPrint buffer. This insures that all messages will be saved in case you need to see them later. If you have a megabyte of memory to spare, you might use the following command:

```
kdbgctrl -sdb 0x100000
```

## Debug Universal Drivers - Step by Step Lab (Echo Kernel-Mode)

This lab introduces the WinDbg kernel debugger. WinDbg is used to debug the echo kernel mode sample driver code.

### Lab objectives

This lab includes exercises that introduce the debugging tools, teach common debugging commands, illustrate the use of break points, and show the use of the debugging extensions.

In this lab, a live kernel debug connection is used to explore the following:

- Use the Windows debugger commands
- Use standard commands (Call stacks, variables, threads, IRQL)
- Use advanced driver debugging commands (!commands)
- Use symbols
- Set breakpoints in live debugging
- View call stacks
- Display the Plug and Play device tree
- Work with thread and process context

**Note** When working with the Windows debugger, there are two types of debugging that can be performed - user or kernel mode debugging.

*User mode* - Applications and subsystems run on the computer in user mode. Processes that run in user mode do so within their own virtual address spaces. They are restricted from gaining direct access to many parts of the system, including system hardware, memory that was not allocated for their use, and other portions of the system that might compromise system integrity. Because processes that run in user mode are effectively isolated from the system and other user mode processes, they cannot interfere with these resources.

*Kernel mode* - Kernel mode is the processor access mode in which the operating system and privileged programs run. Kernel mode code has permission to access any part of the system, and is not restricted like user mode code. It can gain access to any part of any other process running in either user mode or kernel mode. Much of the core OS functionality and many hardware device drivers run in kernel mode.

This lab will focus on kernel mode debugging, as that is the method used to debug many device drivers.

This exercise covers debug commands that are frequently used during both user-mode and kernel-mode debugging. The exercise also covers debug extensions (sometimes called "!commands") that are used for kernel-mode debugging.

### Lab setup

You will need the following hardware to be able to complete the lab.

- A laptop or desktop computer (host) running Windows 10

- A laptop or desktop computer (target) running Windows 10
- A network cross over cable or a network hub and network cables to connect the two PCs
- Access to the internet to download symbol files

You will need the following software to be able to complete the lab.

- Visual Studio 2015
- Windows 10 SDK
- Windows 10 WDK
- The sample echo driver for Windows 10

The lab has the following seven sections.

- [Section 1: Connect to a kernel mode WinDbg session](#)
- [Section 2: Kernel mode debugging commands and techniques](#)
- [Section 3: Download and build the KMDF Universal Echo Driver](#)
- [Section 4: Install the KMDF Echo driver sample on the target system](#)
- [Section 5: Use WinDbg to display information about the driver](#)
- [Section 6: Display plug and play device tree information](#)
- [Section 7: Work with breakpoints and source code](#)
- [Section 8: View variables and call stacks](#)
- [Section 9: Display processes and threads](#)
- [Section 10: IRQL, Registers and Ending the WinDbg session](#)
- [Section 11: Windows debugging resources](#)

## Section 1: Connect to a kernel mode WinDbg session

*In Section 1, you will configure network debugging on the host and target system.*

The PCs in this lab need to be configured to use an Ethernet network connection for kernel debugging.

This lab uses two PCs. Windows debugger runs on the “host” system and the KMDF Echo driver runs on the “target” system.

The “<-Host” on the left is connected using a cross over ethernet cable to the “->Target” on the right.

The steps in the lab assume that you are using a cross over network cable, but the lab should also work if you can plug both the host and the target directly into a network hub.

To work with kernel mode applications and using Windbg, we recommend that you use the KDNET over Ethernet transport. For information about how to use the Ethernet transport protocol, see [Getting Started with WinDbg \(Kernel-Mode\)](#). For more information about setting up the target computer, see [Preparing a Computer for Manual Driver Deployment](#) and [Setting Up Kernel-Mode Debugging over a Network Cable Manually](#).

### Configure kernel-mode debugging using a crossover ethernet cable

Follow the next steps to enable kernel mode debugging on the target system.

#### < On the host system

1. Open a command prompt on the host system and type **ipconfig** to determine its IP address.

```
C:\>ipconfig
Windows IP Configuration
Ethernet adapter Ethernet:
 Connection-specific DNS Suffix . :
 Link-local IPv6 Address : fe80::c8b6:db13:d1e8:b13b%3
 Autoconfiguration IPv4 Address. . . : 169.182.1.1
 Subnet Mask : 255.255.0.0
 Default Gateway :
```

2. Record the IP address of the Host System: \_\_\_\_\_

#### -> On the target system

3. Open a command prompt on the target system and use the **ping** command to confirm network connectivity between the two systems. Use the IP address of the host system you recorded instead of the one shown in the sample output.

```
C:\> ping 169.182.1.1

Pinging 169.182.1.1 with 32 bytes of data:
Reply from 169.182.1.1: bytes=32 time=1ms TTL=255
Reply from 169.182.1.1: bytes=32 time<1ms TTL=255
Reply from 169.182.1.1: bytes=32 time<1ms TTL=255
Reply from 169.182.1.1: bytes=32 time<1ms TTL=255

Ping statistics for 169.182.1.1:
 Packets: Sent = 4, Received = 4, Lost = 0 (0% loss),
 Approximate round trip times in milli-seconds:
 Minimum = 0ms, Maximum = 1ms, Average = 0ms
```

Enable kernel mode debugging on the target system by completing the following steps.

1. On the target computer, open a Command Prompt window as Administrator. Enter this command to enable debugging.

```
C:\> bcdedit /set {default} DEBUG YES
```

2. Type this command to enable test signing.

```
C:\> bcdedit /set TESTSIGNING ON
```

3. Type this command to set the IP address of the host system. Use the IP address of the host system that you recorded earlier, not the one shown.

```
C:\> bcdedit /dbgsettings net hostip:192.168.1.1 port:50000 key:1.2.3.4
```

4. Type this command to confirm that the dbgsettings they are set properly.

```
C:\> bcdedit /dbgsettings
key 1.2.3.4
debugtype NET
hostip 169.168.1.1
port 50000
dhcp Yes
The operation completed successfully.
```

#### Note

#### Firewalls and debuggers

If you receive a pop up message from the firewall, if you wish to use the debugger, unblock the types of networks that you desire.

#### <- On the host system

1. On the host computer, open a Command Prompt window as Administrator. Change to the WinDbg.exe directory. We will use the x64 version of WinDbg.exe from the Windows WDK that was installed as part of the Windows kit installation.

```
C:\> Cd C:\Program Files(x86)\Windows Kits\10.0\Debuggers\x64
```

2. Launch WinDbg with remote user debug using the following command. The value for the key and port match what we set earlier using BCDEdit on the target.

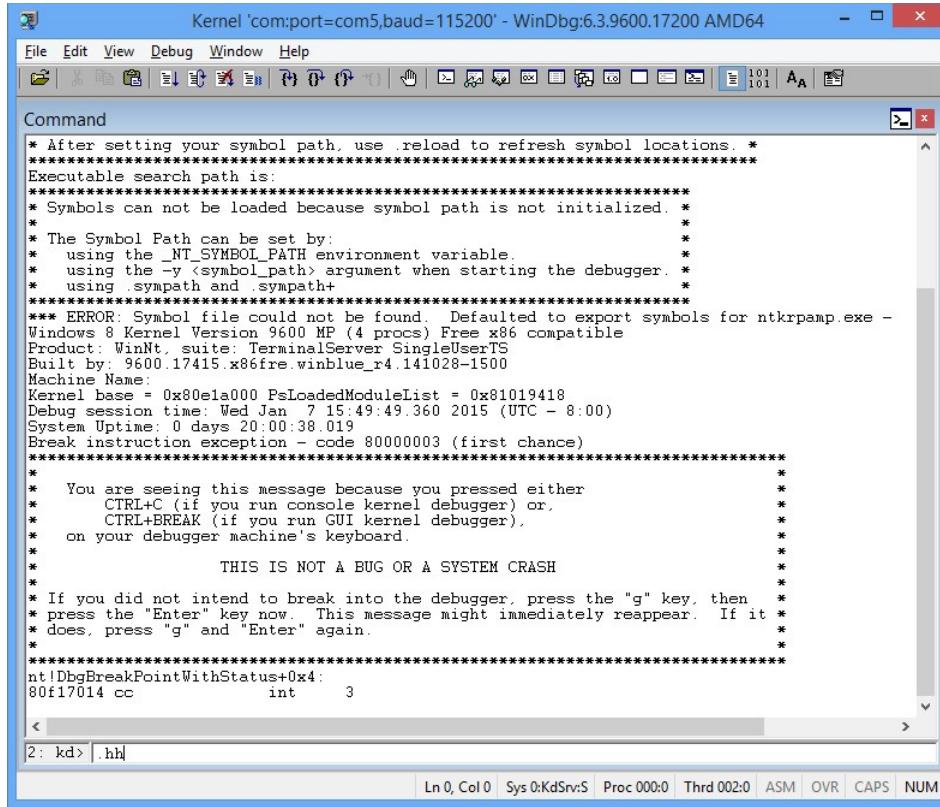

```
WinDbg -k net:port=50000,key=1.2.3.4
```

#### ->On the target system

Reboot the target system.

#### <-On the host system

In a minute or two, debug output should be displayed on the host system.

The Debugger Command window is the primary debugging information window in WinDbg. You can enter debugger commands and view the command output in this window.

The Debugger Command window is split into two panes. You type commands in the smaller pane (the command entry pane) at the bottom of the window and view the command output in the larger pane at the top of the window.

In the command entry pane, use the up arrow and down arrow keys to scroll through the command history. When a command appears, you can edit it or press **ENTER** to run the command.

## Section 2: Kernel mode debugging commands and techniques

*In Section 2, you will use debug commands to display information about the target system.*

### <- On the host system

#### Enable Debugger Markup Language (DML) with .prefer\_dml

Some debug commands will display text using Debugger Markup Language that you can click on to quickly gather more information.

1. Use Ctrl+Break (Scroll Lock) in WinDbg to break into the code running on the target system. It may take a bit of time for the target system to respond.
2. Type the following command to enable DML in the debugger command window.

```
0: kd> .prefer_dml 1
DML versions of commands on by default
```

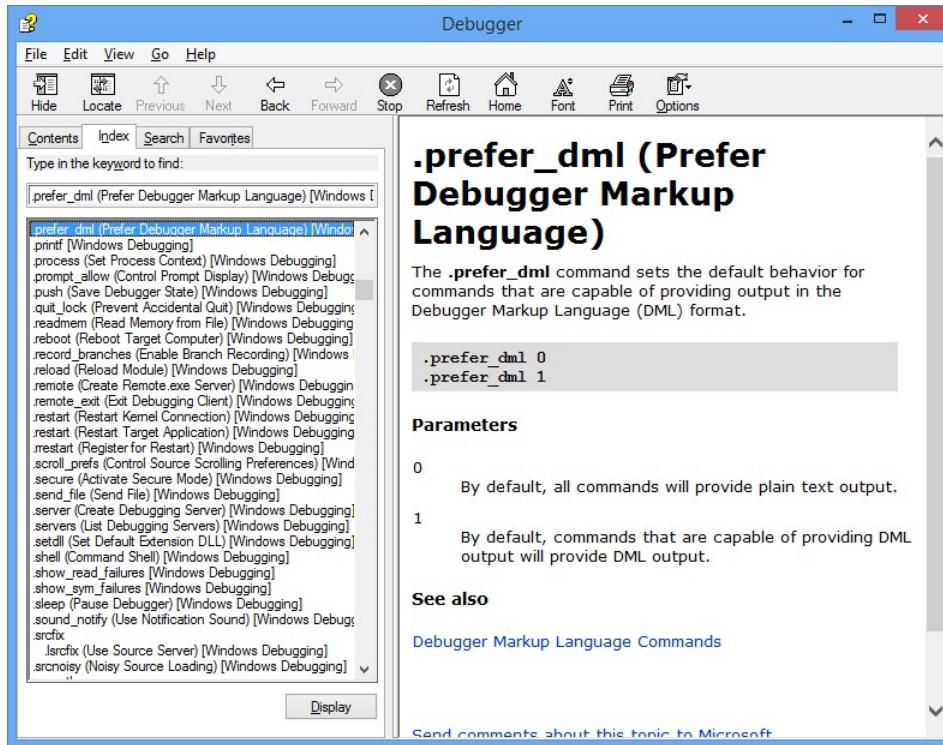

#### Use .hh to get help

You can access reference command help using the **.hh** command.

3. Type the following command to view the command reference help for **.prefer\_dml**.

```
0: kd> .hh .prefer_dml
```

The Debugger help file will display help for the **.prefer\_dml** command.

### Display the version of Windows on the target system

5. Display detailed version information on the target system by typing the [vertarget \(Show Target Computer Version\)](#) command in the WinDbg window.

```
0: kd> vertarget
Windows 10 Kernel Version 9926 MP (4 procs) Free x64
Product: WinNT, suite: TerminalServer SingleUserTS
Built by: 9926.0.amd64fre.fbl_awesome1501.150119-1648
Machine Name: ""
Kernel base = 0xfffffff801`8d283000 PsLoadedModuleList = 0xfffffff801`8d58aef0
Debug session time: Fri Feb 20 10:15:17.807 2015 (UTC - 8:00)
System Uptime: 0 days 01:31:58.931
```

### List the loaded modules

6. You can verify that you are working with the right kernel mode process by displaying the loaded modules by typing the [!m \(List Loaded Modules\)](#) command in the WinDbg window.

```
0: Kd> !m
start end module name
fffff801`09200000 fffff801`0925f000 volmgrx (no symbols)
fffff801`09261000 fffff801`092de000 ncupdate_GenuineIntel (no symbols)
fffff801`092de000 fffff801`092ec000 werkernel (export symbols) werkernel.sys
fffff801`092ec000 fffff801`0934d000 CLFS (export symbols) CLFS.SYS
fffff801`0934d000 fffff801`0936f000 tm (export symbols) tm.sys
fffff801`0936f000 fffff801`09384000 PSCHED (export symbols) PSCHED.dll
fffff801`09384000 fffff801`0938e000 BOOTVID (export symbols) BOOTVID.dll
fffff801`0938e000 fffff801`093f7000 spaceport (no symbols)
fffff801`09400000 fffff801`094cf000 Wdf01000 (no symbols)
fffff801`094d9000 fffff801`09561000 CI (export symbols) CI.dll
...
```

**Note** Output that has been omitted is indicated with "..." in this lab.

7. To request detailed information about a specific module, use the v (verbose) option as shown.

```
0: Kd> !m v m tcpip
Browse full module list
start end module name
fffff801`09eeb000 fffff801`0a157000 tcpip (no symbols)
Loaded symbol image file: tcpip.sys
Image path: \SystemRoot\System32\drivers\tcpip.sys
Image name: tcpip.sys
Browse all global symbols functions data
Timestamp: Sun Nov 09 18:59:03 2014 (546029F7)
CheckSum: 00263DB1
ImageSize: 0026C000
Translations: 0000.04b0 0000.04e4 0409.04b0 0409.04e4
```

Unable to enumerate user-mode unloaded modules, Win32 error 0n30

8. Because we have yet to set the symbol path and loaded symbols, limited information is available in the debugger.

### Section 3: Download and build the KMDF universal echo driver

In Section 3, you will download and build the KMDF universal echo driver.

Typically, you would be working with your own driver code when you use WinDbg. To become familiar with WinDbg operation, the KMDF Template "Echo" sample driver will be used. With the source code available, it will also be easier to understand the information that is displayed in WinDbg. In addition, this sample will be used to illustrate how you can single step through native kernel mode code. This technique can be very valuable for debugging complex kernel mode code issues.

To download and build the Echo sample audio driver, complete the following steps.

#### 1. Download and extract the KMDF Echo sample from GitHub

You can use a browser to view the echo sample in GitHub here:

<https://github.com/Microsoft/Windows-driver-samples/tree/97cf5197cf5b882b2c689d8dc2b555f2edf8f418/general/echo/kmdf>

You can read about the sample here:

<https://github.com/Microsoft/Windows-driver-samples/blob/97cf5197cf5b882b2c689d8dc2b555f2edf8f418/general/echo/kmdf/ReadMe.md>

You can browse all of the universal driver samples here:

<https://github.com/Microsoft/Windows-driver-samples>

The KMDF Echo sample is located in the general folder.

This screenshot shows the GitHub repository page for 'Microsoft / Windows-driver-samples'. The repository has 9 commits, 1 branch, 0 releases, and 3 contributors. The 'general' folder is highlighted with a red box. The 'Download ZIP' button is also highlighted with a red box.

| Commit              | Author      | Date        | Message                    |
|---------------------|-------------|-------------|----------------------------|
| 9 commits           | barrygolden | 12 days ago | authored                   |
| avstream/samplemft0 |             | 14 days ago | samples update for //build |
| bluetooth           |             | 14 days ago | terminology changes        |
| filesys             |             | 14 days ago | terminology changes        |

| hid                 |             | 14 days ago | samples update for //build |
| network             |             | 14 days ago | terminology changes        |

a. For this lab, we will download the universal driver samples in one zip file.

<https://github.com/Microsoft/Windows-driver-samples/archive/master.zip>

b. Download the master.zip file to your local hard drive.

c. Right-click *Windows-driver-samples-master.zip*, and choose **Extract All**. Specify a new folder, or browse to an existing one that will store the extracted files. For example, you could specify *C:\DriverSamples\* as the new folder into which the files will be extracted.

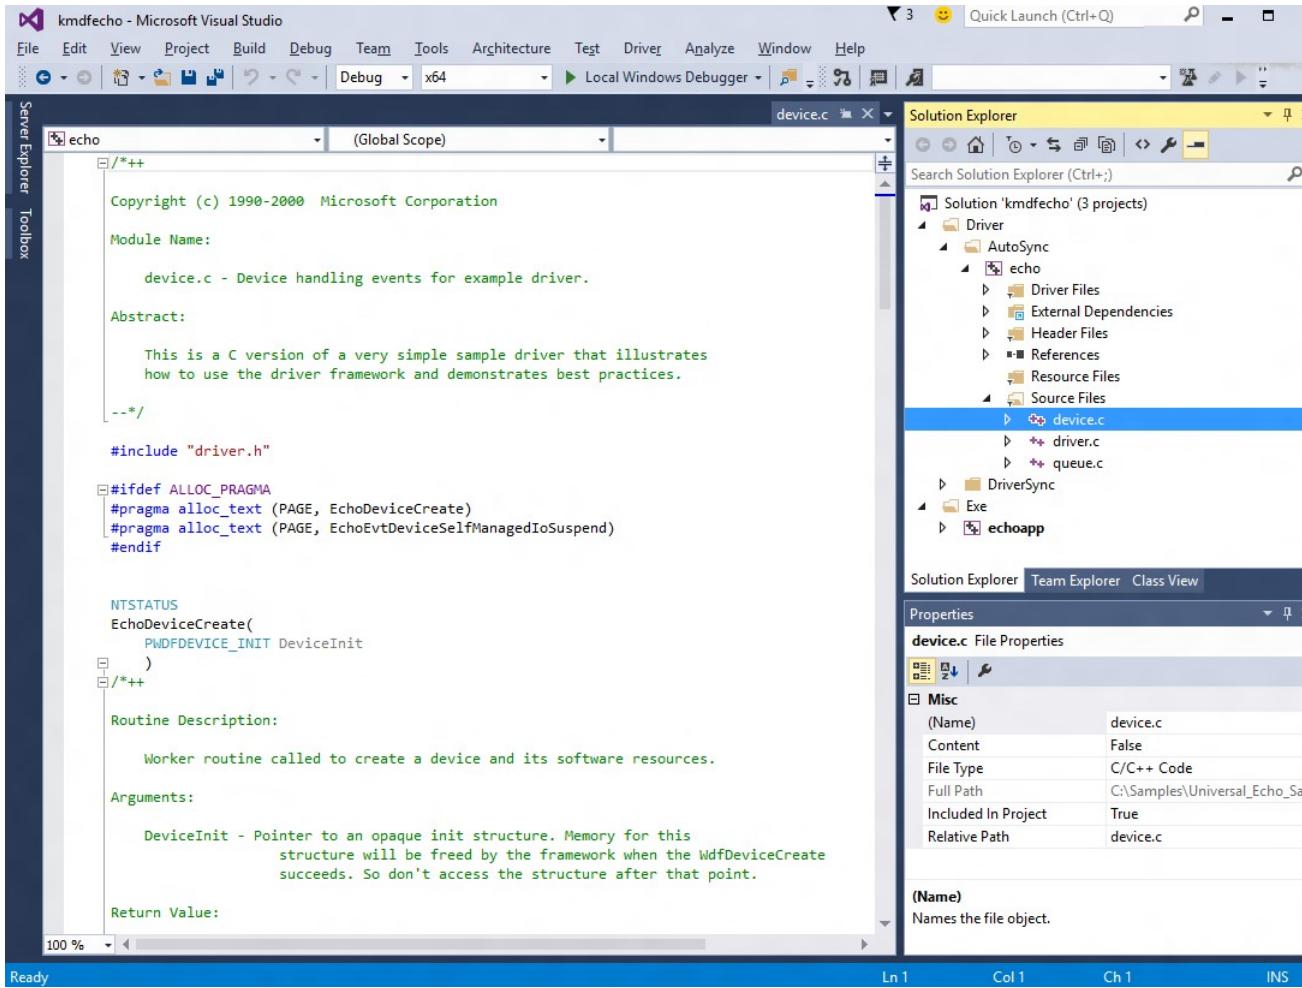

d. After the files are extracted, navigate to the following subfolder.

*C:\DriverSamples\general\echo\kmdf*

#### 2. Open the driver solution in Visual Studio

In Microsoft Visual Studio, click **File > Open > Project/Solution...** and navigate to the folder that contains the extracted files (for example, *C:\DriverSamples\general\echo\kmdf*). Double-click the *kmdfecho* solution file to open it.

In Visual Studio, locate the Solution Explorer. (If this is not already open, choose **Solution Explorer** from the **View** menu.) In Solution Explorer, you can see one solution that has three projects.

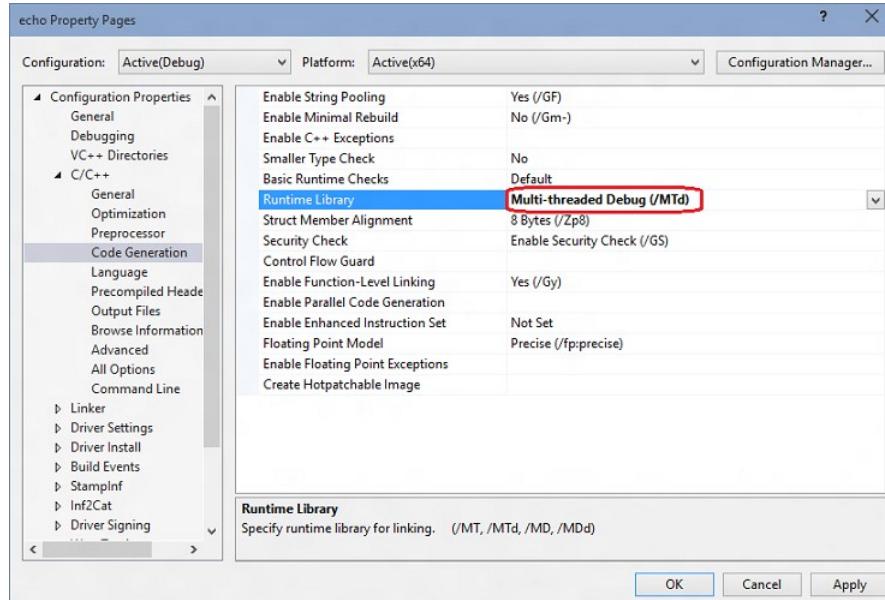

### 3. Set the sample's configuration and platform

In Solution Explorer, right-click **Solution 'kmdfecho' (3 projects)**, and choose **Configuration Manager**. Make sure that the configuration and platform settings are the same for the three projects. By default, the configuration is set to "Win10 Debug", and the platform is set to "Win64" for all the projects. If you make any configuration and/or platform changes for one project, you must make the same changes for the remaining three projects.

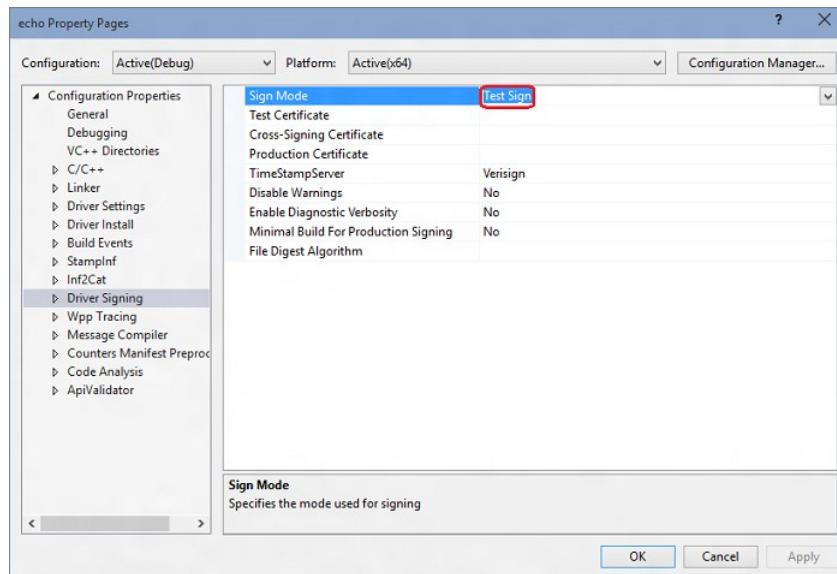

### 4. Set the runtime library

Set the runtime library - Change Runtime Library from DLL version to non DLL version. Without this setting, you have to install the MSVC runtime to the target computer separately.

#### 5. Check driver signing

Open the echo driver's property page and make sure **Driver Signing > Sign Mode** is set to "Test Sign". This is required because Windows requires that drivers are signed.

#### 6. Build the sample using Visual Studio

In Visual Studio, click **Build > Build Solution**.

If all goes well, the build windows will display a message indicating that the build for all three projects succeeded.

#### 7. Locate the built driver files

In File Explorer, navigate to the folder that contains the extracted files for the sample. For example, you would navigate to `C:\DriverSamples\general\echo\kmdf`, if that's the folder you specified earlier. Within that folder, the location of the compiled driver files varies depending on the configuration and platform settings that you selected in the **Configuration Manager**. For example, if you left the default settings unchanged, then the compiled driver files will be saved to a folder named `\x64\Debug` for a 64 bit, debug build.

Navigate to the folder that contains the built files for the Autosync driver:

`C:\DriverSamples\general\echo\kmdf\driver\AutoSync\x64\Debug`. The folder should contain these files:

| File     | Description                                                                       |
|----------|-----------------------------------------------------------------------------------|
| Echo.sys | The driver file.                                                                  |
| Echo.inf | An information (INF) file that contains information needed to install the driver. |

In addition, the echoapp.exe file was built and it should be located here: *C:\DriverSamples\general\echo\kmdf\exe\x64\Debug*

| File        | Description                                                                       |
|-------------|-----------------------------------------------------------------------------------|
| EchoApp.exe | A command prompt executable test file that communicates with the echo.sys driver. |

8. Locate a USB thumb drive or set up a network share to copy the built driver files and the test EchoApp from the host to the target system.

In the next section, you will copy the code to the target system, and install and test the driver.

#### Section 4: Install the KMDF cho driver sample on the target system

*In Section 4, you will use devcon to install the echo sample driver.*

##### -> On the target system

The computer where you install the driver is called the *target computer* or the *test computer*. Typically, this is a separate computer from the computer on which you develop and build the driver package. The computer where you develop and build the driver is called the *host computer*.

The process of moving the driver package to the target computer and installing the driver is called *deploying* the driver. You can deploy the sample echo driver, automatically or manually.

Before you manually deploy a driver, you must prepare the target computer by turning on test signing. You also need to locate the DevCon tool in your WDK installation. After that you're ready to run the built driver sample.

Installing the driver on the target system by performing the following steps.

1. **Prepare the target computer**

Open a Command Prompt window as Administrator. Then enter the following command:

**bededit /set TESTSIGNING ON**

Reboot the target computer.

2. <- On the host system

Navigate to the Tools folder in your WDK installation and locate the DevCon tool. For example, look in the following folder:

*C:\Program Files (x86)\Windows Kits\10.0\Tools\x64\devcon.exe*

Create a folder on the target for the built driver package (for example, *C:\EchoDriver*). Copy all the files from the built driver described earlier on the host computer and save them to the folder that you created on the target computer.

Locate the .cer certificate on the host system, it is in the same folder on the host computer in the folder that contains the built driver files. On the target computer, right-click the certificate file, and click **Install**, then follow the prompts to install the test certificate.

If you need more detailed instructions for setting up the target computer, see [Preparing a Computer for Manual Driver Deployment](#).

3. -> On the target system

##### Install the driver

The following instructions show you how to install and test the sample driver. Here's the general syntax for the devcon tool that you will use to install the driver:

**devcon install <INF file> <hardware ID>**

The INF file required for installing this driver is *echo.inf*. The inf file contains the hardware ID for installing the *echo.sys*. For the echo sample the hardware ID is **root\ECHO**.

On the target computer, open a Command Prompt window as Administrator. Navigate to your driver package folder, and enter the following command:

**devcon install echo.inf root\ECHO**

If you get an error message about *devcon* not being recognized, try adding the path to the *devcon* tool. For example, if you copied it to a folder called *C:\Tools*, then try using the following command:

**c:\tools\devcon install echo.inf root\ECHO**

A dialog box will appear indicating that the test driver is an unsigned driver. Click on “Install this driver anyway” to proceed.

For more detailed instructions, see [Configuring a Computer for Driver Deployment, Testing, and Debugging](#).

After successfully installing the sample driver, you're now ready to test it.

#### 4. Examine the driver in Device Manager

On the target computer, in a Command Prompt window, enter `devmgmt` open Device Manager. In Device Manager, on the View menu, choose Devices by type. In the device tree, locate *Sample WDF Echo Driver* in the Sample Device node.

#### 5. Test the driver

Type `echoapp` to start the test echo app to confirm that the driver is functional.

```
C:\Samples\KMDF_Echo_Sample> echoapp
DevicePath: \\?\root#sample#0005#{cdc35b6e-0be4-4936-bf5f-5537380a7c1a}
Opened device successfully
512 Pattern Bytes Written successfully
512 Pattern Bytes Read successfully
Pattern Verified successfully
30720 Pattern Bytes Written successfully
30720 Pattern Bytes Read successfully
Pattern Verified successfully
```

#### Section 5: Use WinDbg to display information about the driver

*In Section 5, you will set the symbol path and use kernel debugger commands to display information about the KMDF echo sample driver.*

View information about the driver by performing the following steps.

##### <On the host system

- If you closed the debugger, open it again using the following command in the administrator command prompt window.

```
WinDbg -k net:port=50000,key=1.2.3.4
```

- Use Ctrl+Break (Scroll Lock) to break into the code running on the target system.

##### ► Setting the symbol path

- To set the symbols path to the Microsoft symbol server in the WinDbg environment, use the `.symfix` command.

```
0: kd> .symfix
```

- To add your local symbol location to use your local symbols, add the path using `.sympath+` and then `.reload /f`.

```
0: kd> .sympath+ C:\DriverSamples\general\echo\kmdf
0: kd> .reload /f
```

**Note** The `.reload` command with the `/f` force option deletes all symbol information for the specified module and reloads the symbols. In some cases, this command also reloads or unloads the module itself.

**Note** You must load the proper symbols to use advanced functionality that WinDbg provides. If you do not have symbols properly configured, you will receive messages indicating that symbols are not available when you attempt to use functionality that is dependent on symbols.

```
0:000> dv
Unable to enumerate locals, HRESULT 0x80004005
Private symbols (symbols.pri) are required for locals.
Type ".hh dbgerr005" for details.
```

#### Note

##### Symbol servers

There are a number of approaches that can be used to work with symbols. In many situations, you can configure the PC to access symbols from a symbol server that Microsoft provides when they are needed. This walkthrough assumes that this approach will be used. If the symbols in your environment are in a different location, modify the steps to use that location. For additional information, see [Symbol Stores and Symbol Servers](#).

#### Note

##### Understanding source code symbol requirements

To perform source debugging, you must build a checked (debug) version of your binaries. The compiler will create symbol files (.pdb files). These symbol files will show the debugger how the binary instructions correspond to the source lines. The actual source files themselves must also be accessible to the debugger.

The symbol files do not contain the text of the source code. For debugging, it is best if the linker does not optimize your code. Source debugging and access to local variables are more difficult, and sometimes nearly impossible, if the code has been optimized. If you are having problems viewing local variables or source lines, set the following build options:

```
set COMPILE_DEBUG=1
set ENABLE_OPTIMIZER=0
```

- Type the following in the command area of the debugger to display information about the echo driver :

```
0: kd> lm m echo* v
Browse full module list
start end module name
fffff801`4ae80000 fffff801`4ae89000 ECHO (private pdb symbols) C:\Samples\KMDF_ECHO_SAMPLE\echo.pdb
 Loaded symbol image file: ECHO.sys
 Image path: \SystemRoot\system32\DRIVERS\ECHO.sys
 Image name: ECHO.sys
...
...
```

For information, see [lm](#).

- Because we set prefer\_dml =1 earlier, some elements of the output are hot links that you can click on. Click on the *Browse all global symbols link* in the debug output to display information about items symbols that start with the letter “a”.

```
0: kd> x /D Echo!a*
```

- As it turns out, the echo sample doesn't contain any symbols that start with the letter “a”, so to display information about all of the symbols associated with echo driver that start with Echo, type x ECHO!Echo\*.

```
0: kd> x ECHO!Echo*
fffff801`0bf95690 ECHO!EchoEvtIoQueueContextDestroy (void *)
fffff801`0bf95000 ECHO!EchoEvtDeviceSelfManagedIoStart (struct WDFDEVICE__ *)
fffff801`0bf95ac0 ECHO!EchoEvtTimerFunc (struct WDFTIMER__ *)
fffff801`0bf9b120 ECHO!EchoEvtDeviceSelfManagedIoSuspend (struct WDFDEVICE__ *)
...
...
```

For information, see [x \(Examine Symbols\)](#).

- The !lmi extension displays detailed information about a module. Type !lmi echo. Your output should be similar to the text shown below.

```
0: kd> !lmi echo
Loaded Module Info: [echo]
 Module: ECHO
 Base Address: fffff8010bf94000
 Image Name: ECHO.sys
...
...
```

- Use the !dh extension to display header information as shown below.

```
0: kd> !dh echo
File Type: EXECUTABLE IMAGE
FILE HEADER VALUES
 14C machine (i386)
 6 number of sections
54AD8A42 time date stamp Wed Jan 07 11:34:26 2015
...
...
```

- Setting the debug mask

Type the following to change the default debug bit mask so that all debug messages from the target system will be displayed in the debugger.

```
0: kd> !ed nt!Kd_DEFAULT_MASK 0xFFFFFFFF
```

Some drivers will display additional information when the mask of 0xFFFFFFFF is used. Set the mask to 0x00000000 if you would like to reduce the amount of information that is displayed.

```
0: kd> !ed nt!Kd_DEFAULT_MASK 0x00000000
```

## Section 6: Displaying Plug and Play device tree information

In Section 6, you will display information about the echo sample device driver and where it lives in the Plug and Play device tree.

Information about the device driver in the plug and play device tree can be useful for troubleshooting. For example, if a device driver is not resident in the device tree, there may be an issue with the installation of the device driver.

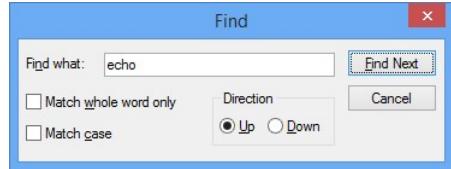

For more information about the device node debug extension, see [!devnode](#).

### <On the host system

- To see all the device nodes in the Plug and Play device tree, enter the **!devnode 0 1** command.

```
0: kd> !devnode 0 1
Dumping IopRootDeviceNode (= 0xfffffe0005a3a8d30)
DevNode 0xfffffe0005a3a8d30 for PDO 0xfffffe0005a3a9e50
 InstancePath is "HTREE\ROOT\0"
 State = DeviceNodeStarted (0x308)
 Previous State = DeviceNodeEnumerateCompletion (0x30d)
 DevNode 0xfffffe0005a3a3d30 for PDO 0xfffffe0005a3a4e50
 InstancePath is "ROOT\volmgr\0000"
 ServiceName is "volmgr"
 State = DeviceNodeStarted (0x308)
 Previous State = DeviceNodeEnumerateCompletion (0x30d)
 DevNode 0xfffffe0005a324560 for PDO 0xfffffe0005bd95ca0...
...
```

- Use Ctrl+F to search in the output that is generated to look for the name of the device driver, *echo*.

- The echo device driver should be loaded. Use the **!devnode 0 1 echo** command to display plug and play information associated with our echo device driver as shown below.

```
0: Kd> !devnode 0 1 echo
Dumping IopRootDeviceNode (= 0xfffffe0007b725d30)
DevNode 0xfffffe0007b71a630 for PDO 0xfffffe0007b71a960
 InstancePath is "ROOT\SAMPLE\0000"
 ServiceName is "ECHO"
 State = DeviceNodeStarted (0x308)
 Previous State = DeviceNodeEnumerateCompletion (0x30d)
...
```

- The output displayed in the previous command includes the PDO associated with the running instance of our driver, in this example it is *0xfffffe0007b71a960*. Enter the **!devobj<PDO address>** command to display plug and play information associated with the echo device driver on your PC. Use the PDO address that **!devnode** displays on your PC, not the one shown here.

```
0: kd> !devobj 0xfffffe0007b71a960
Device object (fffffe0007b71a960) is for:
 0000000e \Driver\PnpManager DriverObject fffffe0007b727e60
Current Irp 00000000 RefCount 0 Type 00000004 Flags 00001040
Dacl fffffc102c9b36031 DevExt 00000000 DevObjExt fffffe0007b71aab0 DevNode fffffe0007b71a630
ExtensionFlags (0x00000800) DOE_DEFAULT_SD_PRESENT
Characteristics (0x00000180) FILE_AUTOGENERATED_DEVICE_NAME, FILE_DEVICE_SECURE_OPEN
AttachedDevice (Upper) fffffe000801fee20 \Driver\ECHO
AttachedDevice (Lower) fffffe000801fee20 \Driver\ECHO
Device queue is not busy.
```

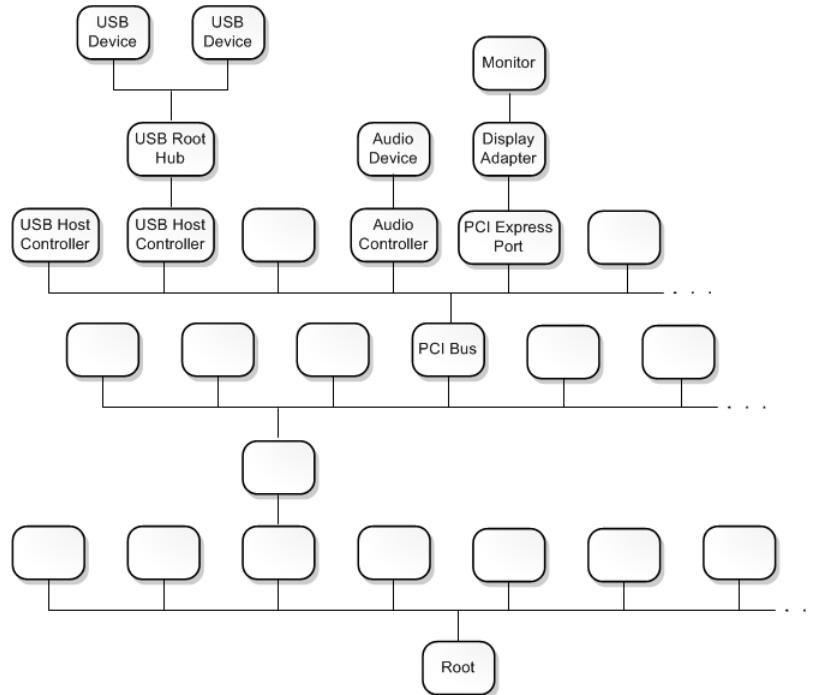

- The output displayed in the **!devnode 0 1** command includes the PDO address associated with the running instance of our driver, in this example it is *0xfffffe0007b71a960*. Enter the **!devstack<PDO address>** command to display plug and play information associated with the device driver. Use the PDO address that **!devnode** displays on your PC, not the one shown below.

```
0: kd> !devstack 0xfffffe0007b71a960
 !DevObj !DrvObj !DevExt ObjectName
 fffffe000801fee20 \Driver\ECHO fffffe0007f72eff0
 > fffffe0007b71a960 \Driver\PnpManager 00000000 0000000e
 !DevNode fffffe0007b71a630 :
 DeviceInst is "ROOT\SAMPLE\0000"
 ServiceName is "ECHO"
```

The output shows that we have a pretty simple device driver stack. The echo driver is a child of the PnPManager node. The PnPManager is a root node.

```
\Driver\ECHO
\Driver\PnpManager
```

This diagram shows a more complex device node tree.

**Note** For more information about more complex driver stacks, see Driver stacks and Device nodes and device stacks on MSDN.

## Section 7: Working with breakpoints and source code

*In Section 7, you will set breakpoints and single step through kernel mode source code.*

## Note

## Setting breakpoints using commands

To be able to step through code and check the values of variables in real time, we need to enable breakpoints and set a path to the source code.

Breakpoints are used to stop code execution at a particular line of code. You can then step forward in the code from that point, to debug that specific section of code.

To set a breakpoint using a debug command, use one of the following **b** commands:

**bp** Sets a breakpoint that will be active until the module it is in is unloaded.

**bu** Sets a breakpoint that will be active until the module it is in is unloaded.

**bm** Sets a breakpoint for a symbol. This command will use bu or bp appropriately and allows wildcards \* to be used to set breakpoints on every symbols that matches (like all methods in a class).

For more information, see [Source Code Debugging in WinDbg](#) in the debugging reference documentation.

<-On the host system

1. Use the WinDbg UI to confirm that **Debug > Source Mode** is enabled in the current WinDbg session.
  2. Add your local code location to the source path by typing the following command.

```
.srcpath+ C:\DriverSamples\KMDF Echo Sample\driver\AutoSync
```

3. Add your local symbol location to the symbol path by typing the following command.

.sympath C:\DriverSamples\KMDF Echo Sample\driver\AutoSync

4. We will use the **x** command to examine the symbols associated with the echo driver to determine the function name to use for the breakpoint. We can use a wild card or Ctrl+F to locate the **DeviceAdd** function name.

```
0: kd> x ECHO!EchoEvt*
8b4c7490 ECHO!EchoEvtIoQueueContextDestroy (void *)
8b4c7000 ECHO!EchoEvtDeviceSelfManagedIoStart (struct WDFDEVICE__ *)
8b4c7820 ECHO!EchoEvtTimerFunc (struct WDFTIMER__ *)
8b4cb0e0 ECHO!EchoEvtDeviceSelfManagedIoSuspend (struct WDFDEVICE__ *)
8b4c75d0 ECHO!EchoEvtIoWrite (struct WDFQUEUE__ *, struct WDFREQUEST__ *, unsigned int)
8b4cb170 ECHO!EchoEvtDeviceAdd (struct WDFDRIVER__ *, struct
```

The output above shows that **DeviceAdd** method for our echo driver is *ECHO!EchoEvtDeviceAdd*.

Alternatively, we could review the source code to locate the desired function name for our breakpoint.

- Set the breakpoint with the **bm** command using the name of the driver, followed by the function name (for example **AddDevice**) where you want to set the breakpoint, separated by an exclamation mark. We will use **AddDevice** to watch the driver being loaded.

```
0: kd> bm ECHO!EchoEvtDeviceAdd
1: ffffff801`0bf9b1c0 @"ECHO!EchoEvtDeviceAdd"
```

#### Note

You can use different syntax in conjunction with setting variables like <module>!<symbol>, <class>:<method>, '<file.cpp>:<line number>', or skip a number of times <condition> <#>. For more information, see [Conditional breakpoints in WinDbg and other Windows debuggers](#).

- List the current breakpoints to confirm that the breakpoint was set by typing the **bl** command.

```
0: kd> bl
1 e ffffff801`0bf9b1c0 0001 (0001) ECHO!EchoEvtDeviceAdd
```

The "e" in the output shown above indicates that the breakpoint number 1 is enabled to fire.

- Restart code execution on the target system by typing the **go** command **g**.

#### 8. -> On the target system

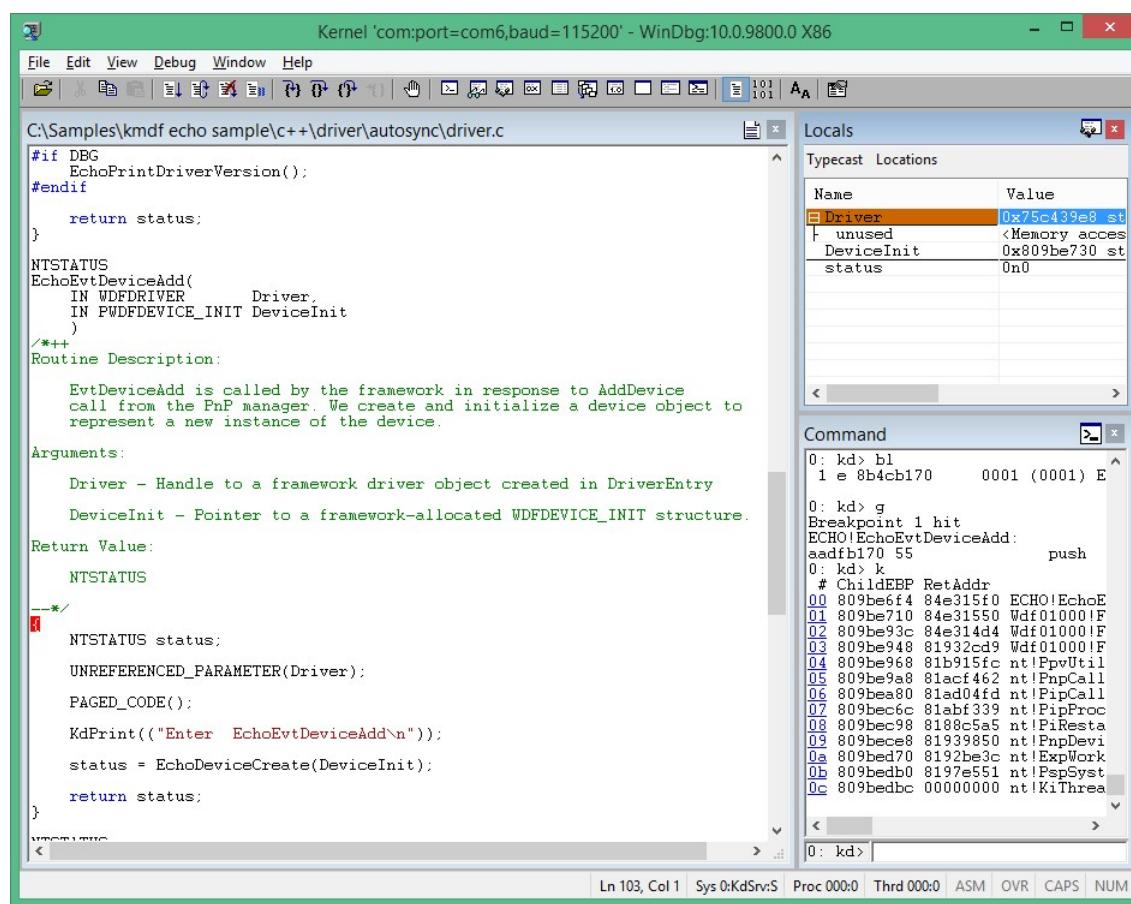

In Windows, open **Device Manager** using the icon or by entering **mmc devmgmt.msc**. In Device Manager, expand the **Samples** node.

- Right-click on the KMDF Echo driver entry and select **Disable** from the menu.

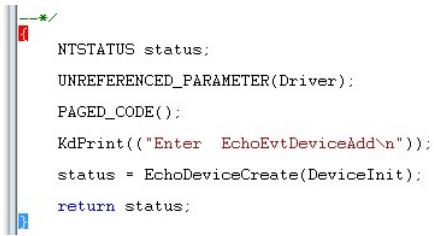

- Right-click on the KMDF Echo driver entry again and select **Enable** from the menu.

#### 11. <- On the host system

When the driver is enabled, the *AddDevice* debug breakpoint should fire, and the execution of the driver code on the target system should halt. When the breakpoint is hit, the execution should be stopped at the start of the *AddDevice* routine. The debug command output will display "Breakpoint 1 hit".

- Step through the code line-by-line by typing the **p** command or pressing F10 until you reach the following end of the *AddDevice* routine. The Brace character "}" will be highlighted as shown.

```

/*
NTSTATUS status;
UNREFERENCED_PARAMETER(Driver);
PAGED_CODE();
KdPrint(("Enter EchoEvtDeviceAdd\n"));
status = EchoDeviceCreate(DeviceInit);
return status;

```

13. In the next section, we will examine the state of the variables after the DeviceAdd code has executed.

#### Note

##### Modifying breakpoint state

You can modify existing breakpoints by using the following commands:

- bl Lists breakpoints.
- bc Clears a breakpoint from the list. Use bc \* to clear all breakpoints.
- bd Disables a breakpoint. Use bd \* to disable all breakpoints.
- be Enables a breakpoint. Use be \* to enable all breakpoints.

Alternatively, you can also modify breakpoints by clicking **edit > breakpoints** in WinDbg. Note that the breakpoint dialog box only works with existing breakpoints. New breakpoints must be set from the command line.

#### Note

##### Setting memory access breakpoints

You can also set breakpoints that fire when a memory location is accessed. Use the **ba** (break on access) command, with the following syntax.

```
ba <access> <size> <address> {options}
```

| Option | Description                                                |
|--------|------------------------------------------------------------|
| e      | execute (when CPU fetches an instruction from the address) |
| r      | read/write (when CPU reads or writes to the address)       |
| w      | write (when the CPU writes to the address)                 |

Note that you can only set four data breakpoints at any given time and it is up to you to make sure that you are aligning your data correctly or you won't trigger the breakpoint (i.e. words must end in addresses divisible by 2, dwds are divisible by 4, and quads by 0 or 8)

For example, to set a read/write breakpoint on a specific memory address, you could use a command like this.

```
ba r 4 0x0003f7bf0
```

#### Note

##### Stepping through code from the Debugger Command window

The following are the commands that you can use to step through your code. The associated keyboard short cuts are shown in parentheses:

- Break in (Ctrl+Break) - This command will interrupt a system as long as the system is running and is in communication with WinDbg (the sequence in the Kernel Debugger is Ctrl+C).
- Run to cursor (F7 or Ctrl+F10) – Place the cursor in a source or disassembly window where you want the execution to break, then press F7; code execution will run to that point. Note that if the flow of code execution does not reach the point indicated by the cursor (e.g., an IF statement isn't executed), WinDbg would not break, because the code execution did not reach the indicated point.
- Run (F5) – Run until a breakpoint is encountered or an event like a bug check occurs.
- Step over (F10) – This command causes code execution to proceed one statement or one instruction at a time. If a call is encountered, code execution passes over the call without entering the called routine. (If the programming language is C or C++ and WinDbg is in source mode, source mode can be turned on or off using **Debug->Source Mode**).
- Step in (F11) – This command is like step-over, except that the execution of a call does go into the called routine.
- Step out (Shift+F11) – This command causes execution to run to and exit from the current routine (current place in the call stack). This is useful if you've seen enough of the routine.

For more information, see [Source Code Debugging in WinDbg](#) in the debugging reference documentation.

## Section 8: Viewing variables and call stacks

In Section 8, you will display information about variables and call stacks.

This lab assumes that you are stopped at the `AddDevice` routine using the process described earlier. To view the output shown here, repeat the steps described previously, if necessary.

### <- On the host system

#### Display variables

Use the **view> local** menu item to display local variables.

| Name       | Value                                        |
|------------|----------------------------------------------|
| Driver     | 0x00001fff`8087d7f8 struct WDFDRIVER__ *     |
| unused     | <Memory access error>                        |
| DeviceInit | 0xfffffd000`b835b190 struct WDFDEVICE_INIT * |
| status     | On0                                          |

#### Global variables

You can find the location of a global variable address by typing `? <variable name>`.

#### Local variables

You can display the names and values of all local variables for a given frame by typing the **dv** command.

```
0: kd> dv
Driver = 0x00001fff`7ff9c838
DeviceInit = 0xfffffd001`51978190
status = On0
```

#### Callstacks

##### Note

The call stack is the chain of function calls that have led to the current location of the program counter. The top function on the call stack is the current function, and the next function is the function that called the current function, and so on.

To display the call stack, use the **k\*** commands:

**kb** Displays the stack and first three parameters.

**kp** Displays the stacks and the full list of parameters.

**kn** Allows you to see the stack with the frame information next to it.

### <- On the host system

- If you want to keep the call stack available, you can click **view > call stack** to view it. Click on the columns at the top of the window to toggle the display of additional information.

- Use the **kn** command to show the call stack while debugging the sample adapter code in a break state.

```
3: kd> kn
Child-SP RetAddr Call Site
00 fffffd001`51978110 ffffff801`0942f55b ECHO!EchoEvtDeviceAdd+0x66 [c:\Samples\kmdf echo sample\c++\driver\autosync\driver.c @ 138]
01 (Inline Function) ----- Wdf01000!FxDriverDeviceAdd::Invoke+0x30 [d:\wbrtm\minkernel\wdf\framework\shared\inc\private\common\f
02 fffffd001`51978150 ffffff801`eed8097d Wdf01000!FxDriver::AddDevice+0xab [d:\wbrtm\minkernel\wdf\framework\shared\core\km\fxdriverkm.cpp @ 7
03 fffffd001`51978570 ffffff801`ef129423 nt!PpvUtilCallAddDevice+0x35 [d:\9142\minkernel\ntos\io\pnpmgr\verifier.c @ 104]
```

```
04 fffffd001`519785b0 ffffff801`ef0c4112 nt!PnpCallAddDevice+0x63 [d:\9142\minkernel\ntos\io\pnpmgr\enum.c @ 7397]
05 fffffd001`51978630 ffffff801`ef0c344f nt!PipCallDriverAddDevice+0x6e2 [d:\9142\minkernel\ntos\io\pnpmgr\enum.c @ 3390]
...
```

The call stack shows that the kernel (nt) called into plug and play code (PnP), that called driver framework code (Wdf) that subsequently called the echo driver **DeviceAdd** function.

## Section 9: Displaying processes and threads

### Processes

*In Section 9, you will display information about the process and threads running in kernel mode.*

#### Note

You can display or set process information by using the [!process](#) debugger extension. We will set a breakpoint to examine the process that are used when a sound is played.

#### 1. <- On the host system

Type the **dv** command to examine the locale variables associated with the **EchoEvtIo** routine as shown.

```
0: kd> dv ECHO!EchoEvtIo*
ECHO!EchoEvtIoQueueContextDestroy
ECHO!EchoEvtIoWrite
ECHO!EchoEvtIoRead
```

#### 2. Clear the previous breakpoints using **bc \***.

```
0: kd> bc *
```

#### 3. Set a symbol breakpoint on the **EchoEvtIo** routines using the following command.

```
0: kd> bm ECHO!EchoEvtIo*
 2: aaade5490 @"ECHO!EchoEvtIoQueueContextDestroy"
 3: aaade55d0 @"ECHO!EchoEvtIoWrite"
 4: aaade54c0 @"ECHO!EchoEvtIoRead"
```

#### 4. List the breakpoints to confirm that the breakpoint is set properly.

```
0: kd> bl
1 e aabf0490 [c:\Samples\kmdf echo sample\c++\driver\autosync\queue.c @ 197] 0001 (0001) ECHO!EchoEvtIoQueueContextDestroy
...
```

#### 5. Type **g** to restart code execution.

```
0: kd> g
```

#### 6. -> On the target system

Run the EchoApp.exe driver test program on the target system.

#### 7. <- On the host system

When the test app runs, the I/O routine in the driver will be called. This will cause the breakpoint to fire, and execution of the driver code on the target system will halt.

```
Breakpoint 2 hit
ECHO!EchoEvtIoWrite:
fffff801`0bf95810 4c89442418 mov qword ptr [rsp+18h],r8
```

#### 8. Use the **!process** command to display the current process that is involved in running echoapp.exe.

```
0: kd> !process
PROCESS fffffe0007e6a7780
 SessionId: 1 Cid: 03c4 Peb: 7ff7cfec4000 ParentCid: 0f34

 MemoryPriority BACKGROUND
 BasePriority 8
 CommitCharge 138

 THREAD fffffe00080e32080 Cid 03c4.0ec0 Peb: 00007ff7cfec000 Win32Thread: 0000000000000000 RUNNING on processor 1
```

The output shows that the process is associated with the echoapp.exe which was running when our breakpoint on the driver write event was hit. For more information, see [!process](#).

9. Use the **!process 0 0** to display summary information for all processes. In the output, use CTRL+F to locate the same process address for the process associated with the echoapp.exe image. In the example shown below, the process address is fffffe0007e6a7780.

```
...
PROCESS fffffe0007e6a7780
SessionId: 1 Cid: 0f68 Peb: 7ff7cf7a000 ParentCid: 0f34
DirBase: 1f7fb9000 ObjectTable: fffffc001cec82780 HandleCount: 34.
Image: echoapp.exe
...
```

10. Record the process ID associated with echoapp.exe to use later in this lab. You can also use CTRL+C, to copy the address to the copy buffer for later use.

\_\_\_\_\_  
(echoapp.exe process address)

11. Enter **g** as required into the debugger to run the code forward until the echoapp.exe finishes running. It will hit the breakpoint in the read and write event a number of times. When echoapp.exe finishes, break in to the debugger, by pressing CTRL+ScrLk (Ctrl+Break).

12. Use the **!process** command to confirm that you are now running a different process. In the output shown below, the process with the Image value of *System* is different from the *Echo* Image value.

```
1: kd> !process
PROCESS fffffe0007b65d900
SessionId: none Cid: 0004 Peb: 00000000 ParentCid: 0000
DirBase: 001ab000 ObjectTable: fffffc001c9a03000 HandleCount: 786.
Image: System
VadRoot fffffe0007e45930 Vad 14 Clone 0 Private 22. Modified 131605. Locked 64.
DeviceMap fffffc001c9a0c220
Token fffffc001c9a05530
ElapsedTime 21:31:02.516
...
```

The output above shows that a system process fffffe0007b65d900 was running, when we stopped the OS.

13. Now, use the **!process** command to try to look at the process ID that had been associated with echoapp.exe that you recorded earlier. Provide your echoapp.exe process address that you recorded earlier, instead of the example process address shown below.

```
0: kd> !process fffffe0007e6a7780
TYPE mismatch for process object at 82a9acc0
```

The process object is now longer available, as the echoapp.exe process is no longer running.

## Threads

### Note

The commands to view and set threads are very similar to those of processes. Use the [!thread](#) command to view threads. Use [.thread](#) to set the current threads.

#### 1. <- On the host system

Enter **g** into the debugger to restart code execution on the target system.

#### 2. -> On the target system

Run the EchoApp.exe driver test program on the target system.

#### 3. <- On the host system

The breakpoint will be hit and code execution will halt.

```
Breakpoint 4 hit
ECHO!EchoEvtIoRead:
aade54c0 55 push ebp
```

#### 4. To view the threads that are running, type [!thread](#). Information similar to the following should be displayed:

```
0: kd> !thread
THREAD fffffe000809a0880 Cid 0b28.1158 Peb: 00007ff7d00dd000 Win32Thread: 0000000000000000 RUNNING on processor 0
IRP List:
fffffe0007bc5be10: (0006,01f0) Flags: 00060a30 Mdl: 00000000
Not impersonating
DeviceMap fffffc001d83c6e80
Owning Process fffffe0008096c900 Image: echoapp.exe
...
```

Note the image name of *echoapp.exe*, indicating that we are looking at the thread associated with the test app.

5. 4. Use the **!process** command to determine if this is the only thread running in the process associated with echoapp.exe. Note that the thread number of the running thread in the process is the same thread running that the **!thread** command displayed.

```
0: kd> !process

```

**Note** You can alternatively use **!process 0 17** to display detailed information about every process. The output from this command can be lengthy. The output can be searched using Ctrl+F.

7. Use the **!process** command to list process information for both processes running your PC. Provide the process address from your **!process 0 0** output, not the address shown below.

This example output is for the cmd.exe process ID that was recorded earlier. Note that the image name for this process ID is cmd.exe.

```

```

Call stack elements such as **KiCommitThreadWait** indicate that this thread is not running as is expected.

#### Note

For more information about threads and processes, see the following references on MSDN:

[Threads and Processes](#)

[Changing Contexts](#)

## Section 10: IRQL, Registers and Ending the WinDbg session

### Viewing the saved IRQL

In Section 10, you will display the IRQL, and the contents of the registers.

#### <- On the host system

The interrupt request level (IRQL) is used to manage the priority of interrupt servicing. Each processor has an IRQL setting that threads can raise or lower. Interrupts that

occur at or below the processor's IRQL setting are masked and will not interfere with the current operation. Interrupts that occur above the processor's IRQL setting take precedence over the current operation. The [!irql](#) extension displays the interrupt request level (IRQL) on the current processor of the target computer before the debugger break occurred. When the target computer breaks into the debugger, the IRQL changes, but the IRQL that was effective just before the debugger break is saved and is displayed by [!irql](#).

```
0: kd> !irql
Debugger saved IRQL for processor 0x0 -- 2 (DISPATCH_LEVEL)
```

## Viewing the registers

### <On the host system

Display the contents of the registers for the current thread on the current processor by using the [r \(Registers\)](#) command.

```
0: kd> r
rax=000000000000c301 rbx=fffffe00173eed880 rcx=0000000000000001
rdx=000000d800000000 rsi=fffffe00173eed8e0 rdi=fffffe00173eed8f0
rip=fffff803bb757020 rsp=fffffd001f01f8988 rbp=fffffe00173f0b620
r8=000000000000003e r9=fffffe00167a4a000 r10=000000000000001e
r11=fffffd001f01f88f8 r12=0000000000000000 r13=fffffd001f01efdc0
r14=0000000000000001 r15=0000000000000000
iopl=0 nv up ei pl nz na pe nc
cs=0010 ss=0018 ds=002b es=002b fs=0053 gs=002b
nt!DbgBreakPointWithStatus:
fffff803`bb757020 cc int 3
```

Alternatively, you can display the contents of the registers by clicking **view > registers**. For more information see [r \(Registers\)](#).

Viewing the contents of the registers can be helpful when stepping through assembly language code execution and in other scenarios. For more information about assembly language disassembly, see [Annotated x86 Disassembly](#) and [Annotated x64 Disassembly](#).

For information about contents of the register, see [x86 Architecture](#) and [x64 Architecture](#).

## Ending the WinDbg session

### <On the host system

To end a user-mode debugging session, return the debugger to dormant mode, and set the target application to run again, enter the [qd \(Quit and Detach\)](#) command.

Be sure and use the [g](#) command to let the target computer run code, so that it can be used. It also a good idea to clear any break points using [bc \\*](#), so that the target computer won't break and try to connect to the host computer debugger.

```
0: kd> qd
```

For more information, see [Ending a Debugging Session in WinDbg](#) in the debugging reference documentation.

## Section 11: Windows debugging resources

Additional information is available on Windows debugging. Note that some of these books will use older versions of Windows such as Windows Vista in their examples, but the concepts discussed are applicable to most versions of Windows.

## Debugging Resources

Use Debugging Tools for Windows to debug drivers, applications, and services on Windows systems. The core debugging engine in the tool set is called the Windows debugger. Starting with Windows 8, you can use Visual Studio as your interface to the Windows debugger. You can also use the traditional interfaces (WinDbg, CDB, and NTSD), which are included in Debugging Tools for Windows.

## Debugging Tools for Windows: New for Windows 10.0

For Windows 10, Debugging Tools for Windows includes these new features.

### Windows 10, version 1703

This section describes new debugging tools in Windows 10, version 1703.

- Eight new JavaScript topics including [JavaScript Debugger Scripting](#)
- Updates to the [dx \(Display Debugger Object Model Expression\)](#) command, to include new command capabilities.
- New [dtx \(Display Type - Extended Debugger Object Model Information\)](#) command.
- New [!ioctldecode](#) command.
- Updates to [Configuring\\_tools.ini](#) to document additional options for the command line debuggers.
- Published 40 previously undocumented stop codes in [Bug Check Code Reference](#).

### Windows 10, version 1607

This section describes new debugging tools in Windows 10, version 1607.

- New topic about [Debugging a UWP app using WinDbg](#).
- Updates to the 30 most-viewed developer bug check topics in [Bug Check Code Reference](#).

## Windows 10

- [.settings \(Set Debug Settings\)](#) - New command that allows you to set, modify, display, load and save settings in the Debugger.Settings namespace.
- [dx \(Display NatVis Expression\)](#) - Describes the new dx debugger command, which displays object information using the NatVis extension model and LINQ support.
- New commands that work with the NatVis visualization files in the debugger environment.
  - [.nvlist \(NatVis List\)](#)
  - [.nvload \(NatVis Load\)](#)
  - [.nvunload \(NatVis Unload\)](#)
  - [.nvunloadall \(NatVis Unload All\)](#)
- [Bluetooth Extensions \(Bthkd.dll\)](#)
- [Storage Kernel Debugger Extensions](#)
- New Symproxy information including [SymProxy Automated Installation](#). In addition the following topics are updated to cover new SymProxy functionality:
  - [HTTP Symbol Stores](#)
  - [SymProxy](#)
  - [Installing SymProxy](#)
  - [Configuring the Registry](#)
  - [Configuring IIS for SymProxy](#)
- [CDB Command-Line Options](#) - Updated to include new command line options.
- [!analyze](#) - Updated to include information about using this extension with UMDF 2.15.
- [!wdfkd.wdfcrashdump](#) - Updated to include information about using this extension with UMDF 2.15
- [!irp](#) - Updated. Starting with Windows 10 the IRP major and minor code text is displayed in command output.
- [Using Debugger Markup Language](#) - Updated to describe new right click behavior available in the Debugger Markup Language (DML).
- [Crash dump analysis using the Windows debuggers \(WinDbg\)](#) - Performance has increased in taking a memory dump over KDN.
- [Debug Universal Drivers - Step by Step Lab \(Echo Kernel-Mode\)](#) - New step by step lab that shows how to use WinDbg to debug the sample KMDF echo driver.

[Send comments about this topic to Microsoft](#)

## Tools Included in Debugging Tools for Windows

Debugging Tools for Windows includes several tools in addition to the debugging engine and the [Debugging Environments](#). The tools are in the [installation directory](#) of Debugging Tools for Windows.

### [ADPlus](#)

Automatically create memory dump files and log files with debug output from one or more processes.

### [DumpChk](#)

Validate a memory dump file.

### [GFlags](#)

Control registry keys and other settings.

### [Kill](#)

Terminate a process.

### [Logger and LogViewer](#)

Record and display function calls and other actions of a program.

### [PLMDebug](#)

Use the Windows debugger to debug Windows app, which run under Process Lifecycle Management (PLM). With PLMDebug, you can take manual control of suspending, resuming, and terminating a Windows app.

### [Remote Tool](#)

Remotely control any console program, including KD, CDB, and NTSD. See [Remote Debugging Through Remote.exe](#).

### [TList](#)

List all running processes.

### [UMDH](#)

Analyze heap allocations.

### [USBView](#)

Display USB host controllers and connected devices.

#### DbgRpc (Dbgrpc.exe)

Display Microsoft Remote Procedure Call (RPC) state information. See [RPC Debugging](#) and [Using the DbgRpc Tool](#).

#### KDbgCtrl (Kernel Debugging Control, Kdbgctrl.exe)

Control and configure the kernel debugging connection. See [Using KDbgCtrl](#).

#### SrcSrv

A source server that can be used to deliver source files while debugging.

#### SymSrv

A symbol server that the debugger can use to connect to a symbol store.

#### SymProxy

Create a single HTTP symbol server on your network that all your debuggers can point to. This has the benefit of pointing to multiple symbol servers (both internal and external) with a single symbol path, handling all authentication, and increasing performance via symbol caching. Symproxy.dll is in the SymProxy folder in the [installation directory](#).

#### SymChk

Compare executable files to symbol files to verify that the correct symbols are available.

#### SymStore

Create a symbol store. See [Using SymStore](#).

#### AgeStore

Removes old entries in the downstream store of a symbol server or a source server.

#### DBH

Display information about the contents of a symbol file.

#### PDBCopy

Remove private symbol information from a symbol file, and control which public symbols are included in the file.

#### DbgSrv

A process server used for remote debugging. See [Process Servers \(User Mode\)](#).

#### KdSrv

A KD connection server used for remote debugging. See [KD Connection Servers \(Kernel Mode\)](#).

#### DbEngPrx

A repeater (small proxy server) used for remote debugging. See [Repeaters](#).

#### Breakin (Breakin.exe)

Causes a user-mode break to occur in a process. For help, open a Command Prompt window, navigate to the [installation directory](#), and enter **breakin /?**.

#### List (File List Utility) (List.exe)

For help, open a Command Prompt window, navigate to the [installation directory](#), and enter **list /?**.

#### RTList (Remote Task List Viewer) (Rtlist.exe)

List running processes via a DbgSrv process server. For help, open a Command Prompt window, navigate to the [installation directory](#), and enter **rtlist /?**.

## Installation Directory

The default installation directory for 64 bit OS installs for the debugging tools is C:\Program Files (x86)\Windows Kits\10\Debuggers\. If you have a 32-bit OS, you can find the Windows Kits folder under C:\Program Files. To determine if you should use the 32 bit or 64 bit tools, see [Choosing the 32-Bit or 64-Bit Debugging Tools](#).

## Related topics

#### [Tools Related to Debugging Tools for Windows](#)

## ADPlus

ADPlus V7.0 is a total rewrite of ADPlus. ADPlus V7.0 is written in managed code, which allows us to easily add new features. ADPlus.exe keeps the basic functionality of ADPlus.vbs and adds some additional features. Also, there is a new companion called ADPlusManager, which extends ADPlus to a distributed environment like an HPC computer cluster.

### Where to get ADPlus

ADPlus is included in [Debugging Tools for Windows](#).

For ADPlus V7.0 documentation, see adplus.doc in the installation folder for Debugging Tools for Windows.

## DumpChk

DumpChk (the Microsoft Crash Dump File Checker tool) is a program that performs a quick analysis of a crash dump file. This enables you to see summary information about what the dump file contains. If the dump file is corrupt in such a way that it cannot be opened by a debugger, DumpChk reveals this fact.

### Where to get DumpChk

DumpChk.exe is included in [Debugging Tools for Windows](#).

### DumpChk command-line options

**DumpChk [-y SymbolPath] DumpFile**

#### Parameters

**-y SymbolPath**

*SymbolPath* specifies where DumpChk is to search for symbols. Symbol information may be necessary for some dump files. It can also help to improve the information shown in the dump file by allowing symbol names to be resolved.

**DumpFile**

*DumpFile* specifies the crash dump file that is to be analyzed. This may include an absolute or relative directory path or universal naming convention (UNC) path. If *DumpFile* contains spaces, it must be enclosed in quotation marks.

### Using DumpChk

Here is an example in which the dump file is corrupt. The error shown at the end, `DebugClient cannot open DumpFile`, indicates that some kind of corruption must have occurred:

```
C:\Debuggers> dumpchk c:\mydir\dumpfile2.dmp
Loading dump file c:\mydir\dumpfile2.dmp
Microsoft (R) Windows Debugger Version 6.9.0003.113 X86
Copyright (C) Microsoft. All rights reserved.

Loading Dump File [c:\mydir\dumpfile2.dmp]
Could not match Dump File signature - invalid file format
Could not open dump file [c:\mydir\dumpfile2.dmp], HRESULT 0x80004002
"No such interface supported"
**** DebugClient cannot open DumpFile - error 80004002
```

Because this display does not end with the words `Finished dump check`, the dump file is corrupt. The error message at the end explains that the dump file could not be opened.

Note that other errors may be listed, some of which are actually benign. For example, the following error message does not represent a problem:

```
error 3 InitTypeRead(nt!_PEB at 7ffd5000)
```

Here is an example of DumpChk run on a healthy user-mode minidump. The display begins with an overall summary of the dump file, and then gives detailed information about what data is contained in the dump file:

```
C:\Debuggers> dumpchk c:\mydir\dumpfile1.dmp
Loading dump file c:\mydir\dumpfile1.dmp

Microsoft (R) Windows Debugger Version 6.9.0003.113 X86
Copyright (C) Microsoft. All rights reserved.

Loading Dump File [c:\mydir\dumpfile1.dmp]

Finished dump check

```

The output begins by identifying the characteristics of the dump file - in this case, a user-mode minidump with full memory information, including application data but not operating-system data. This is followed by the symbol path being used by DumpChk, and then a summary of the dump file contents.

Because this display ends with the words `Finished dump check`, the dump file is probably not corrupt, and can be opened by a debugger. However, more subtle forms of corruption might still be present in the file.

## GFlags

GFlags (the Global Flags Editor), gflags.exe, enables and disables advanced debugging, diagnostic, and troubleshooting features. It is most often used to turn on indicators that other tools track, count, and log.

### Where to get GFlags

GFlags is included in [Debugging Tools for Windows](#).

### Overview of GFlags

Driver developers and testers often use GFlags to turn on debugging, logging and test features, either directly, or by including GFlags commands in a test script. The page heap verification features can help you to identify memory leaks and buffer errors in kernel-mode drivers.

GFlags has both a dialog box and a command-line interface. Most features are available from both interfaces, but some features are accessible from only one of the interfaces. (See [GFlags Details](#).)

#### Features

- Page heap verification. GFlags now includes the functions of PageHeap (pageheap.exe), a tool that enables heap allocation monitoring. PageHeap was included in previous versions of Windows.
- No reboot required for the Special Pool feature. On Windows Vista and later versions of Windows, you can enable, disable, and configure the Special Pool feature without restarting ("rebooting") the computer. For information, see [Special Pool](#).
- Object Reference Tracing. A new flag enables tracing of object referencing and object dereferencing in the kernel. This new feature of Windows detects when an object reference count is decremented too many times or not decremented even though an object is no longer used. This flag is supported only in Windows Vista and later versions of Windows.
- New dialog box design. The GFlags dialog box has tabbed pages for easier navigation.

#### Requirements

To use most GFlags features, including setting flags in the registry or in kernel mode, or enabling page heap verification, you must be a member of the Administrators group on the computer. However, prior to Windows Vista, users with at least Guest account access can launch a program from the **Global Flags** dialog box.

When features do not work, or work differently, on particular operating system versions, the differences are explained in the description of the feature.

This topic includes:

- [GFlags Overview](#)
- [GFlags Details](#)
- [GFlags Commands](#)
- [GFlags Flag Table](#)
- [GFlags and PageHeap](#)
- [Global Flags Dialog Box](#)
- [GFlags Examples](#)
- [Global Flag Reference](#)

**Note** Incorrect use of this tool can degrade system performance or prevent Windows from starting, requiring you to reinstall Windows.

**Important** Pool tagging is permanently enabled on Windows Server 2003 and later versions of Windows, including Windows Vista. On these systems, the **Enable pool tagging** check box on the **Global Flags** dialog box is dimmed and commands to enable or disable pool tagging fail.

# GFlags Overview

GFlags (gflags.exe), the Global Flags Editor, enables and disables advanced internal system diagnostic and troubleshooting features. You can run GFlags from a Command Prompt window or use its graphical user interface dialog box.

Use GFlags to activate the following features:

### Registry

Set system-wide debugging features for all processes running on the computer. These settings are stored in the **GlobalFlag** registry entry (**HKEY\_LOCAL\_MACHINE\SYSTEM\CurrentControlSet\Control\Session Manager\GlobalFlag**). They take effect when you restart Windows and remain effective until you change them and restart again.

### Kernel flag settings

Set debugging features for this session. These settings are effective immediately, but are lost when Windows shuts down. The settings affect all processes started after this command completes.

### Image file settings

Set debugging features for a particular program. These settings are stored in a GlobalFlag registry entry for each program (**HKEY\_LOCAL\_MACHINE\SOFTWARE\Microsoft\Windows NT\CurrentVersion\Image File Execution Options\ImageFileName\GlobalFlag**). They take effect when you restart the program and remain effective until you change them.

### Debugger

Specify that a particular program always runs in a debugger. This setting is stored in the registry. It is effective immediately and remains effective until you change it. (This feature is available only in the **Global Flags** dialog box.)

### Launch

Run a program with the specified debugging settings. The debugging settings are effective until the program stops. (This feature is available only from the **Global Flags** dialog box.)

### Special Pool

Request that allocation with a specified pool tag or of a specified size are filled from the special pool. This feature helps you to detect and identify the source of errors in kernel pool use, such as writing beyond the allocated memory space, or referring to memory that has already been freed.

Beginning in Windows Vista, you can enable, disable, and configure the special pool feature (**Kernel Special Pool Tag**) as a kernel flags setting, which does not require a reboot, or as a registry setting, which requires a reboot.

### Page heap verification

Enable, disable, and configure page heap verification for a program. When enabled, page heap monitors dynamic heap memory operations, including allocation and free operations, and causes a debugger break when it detects a heap error.

Silent process exit

Enable, disable, and configure monitoring and reporting of silent exits for a process. You can specify actions that occur when a process exits silently, including notification, event logging, and creation of dump files. For more information, see [Monitoring Silent Process Exit](#).

## GFlags Details

GFlags enables and disables system features by editing the Windows registry and internal settings. This section explains the operation of GFlags in detail and includes tips for using GFlags most efficiently.

### General Information

- To display the GFlags dialog box, at the command line, type **gflags** (with no parameters).
- On Windows Server 2003 and earlier versions of Windows, to set flags in the registry or in kernel mode, you must be a member of the Administrators group on the computer. However, users with at least Guest account access can launch a program from the GFlags dialog box.
- GFlags system-level registry settings appear in the registry immediately, but do not take effect until you restart the system.
- GFlags image file registry settings appear in the registry immediately, but do not take effect until you restart the process.
- The debugger and launch features in the GFlags dialog box are program specific. You can only set them on one image file at a time.

### Flag Details

- To clear all flags, set the flag to -FFFFFFF. Setting the flag to 0 adds 0 to the current flag value.
- When you set the flags for an image file to FFFFFFFF (0xFFFFFFFF), Windows clears all flags for the image file and deletes the **GlobalFlag** entry in the image file registry key. The image file registry key is retained.

### Dialog Box and Command Line

You can run GFlags by using its handy dialog box or from the command line. Most features are available in both forms, with the following exceptions.

#### Dialog box only

- Launch. Start a program using the specified flags.
- Run the program in a debugger.
- [Special Pool](#) on systems prior to Windows Vista. On Windows Vista and later versions of Windows, you can configure the Special Pool feature at the command line or in the Gflags dialog box.

#### Command line only

- Set the size of the user mode stack trace database (**/tracedb**).
- Set page heap verification options.

### Registry Information

GFlags settings that are saved between sessions are stored in the registry. You can use the registry APIs, Regedit, or reg.exe to query or change these values. The following table lists the types of settings and where they are stored in the registry.

|                                                                                                   |                                                                                                                                                                             |
|---------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Systemwide settings ("Registry")                                                                  | HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Control\Session Manager\GlobalFlag                                                                                              |
| Program-specific settings ("Image file") for all users of the computer                            | HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Windows NT\CurrentVersion\Image File Execution Options\ImageFileName\GlobalFlag                                                       |
| Silent exit settings for a specific program ("Silent Process Exit") for all users of the computer | HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Windows NT\CurrentVersion\SilentProcessExit\ImageFileName                                                                             |
| Page heap options for an image file for all users of the computer                                 | HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Windows NT\CurrentVersion\Image File Execution Options\ImageFileName\PageHeapFlags                                                    |
| User mode stack trace database size ( <b>tracedb</b> )                                            | HKLM\SOFTWARE\Microsoft\Windows NT\CurrentVersion\Image File Execution Options\ImageFileName\StackTraceDatabaseSizeInMb                                                     |
| Create user mode stack trace database (ust, 0x1000) for an image file                             | Windows adds the image file name to the value of the USTEnabled registry entry (HKLM\SOFTWARE\Microsoft\Windows NT\CurrentVersion\Image File Execution Options\USTEnabled). |
| Load image using large pages if possible                                                          | HKLM\SOFTWARE\Microsoft\Windows NT\CurrentVersion\Image File Execution Options\ImageFileName\UseLargePages                                                                  |
| Special Pool                                                                                      | HKLM\SYSTEM\CurrentControlSet\Control\Session Manager\Memory Management\PoolTag                                                                                             |
| (Kernel Special Pool Tag)                                                                         |                                                                                                                                                                             |
| Verify Start / Verify End                                                                         | HKLM\SYSTEM\CurrentControlSet\Control\Session Manager\Memory Management\PoolTagOverruns. The Verify Start                                                                   |

Debugger for an image file  
Object Reference Tracing

option sets the value to 0. The **Verify End** option sets the value to 1.

## GFlags Commands

To use GFlags, type the following commands at the command line.

You can use the GFlags commands and the [Global Flags Dialog Box](#) interchangeably.

To open the GFlags dialog box:

```
gflags
```

To set or clear global flags in the registry:

```
gflags /r [{+ | -}Flag [{+ | -}Flag...]]
```

To set or clear global flags for the current session:

```
gflags /k [{+ | -}Flag [{+ | -}Flag...]]
```

To set or clear global flags for an image file:

```
gflags /i ImageFile [{+ | -}Flag [{+ | -}Flag...]]
gflags /i ImageFile /tracedb SizeInMB
```

To set or clear the Special Pool feature (Windows Vista and later)

```
gflags {/r | /k} {+ | -}spp {PoolTag | 0xSize}
```

To enable or disable the Object Reference Tracing feature (Windows Vista and later)

```
gflags {/ro | /ko} [/p] [/i ImageFile | /t PoolTag;[PoolTag...]]
```

```
gflags {/ro | /ko} /d
```

To enable and configure page heap verification:

```
gflags /p /enable ImageFile [/full [/backwards] | /random Probability | /size SizeStart SizeEnd | /address AddressStart AddressEnd | /debug ["DebuggerCommand"] | /kdebug] [/unaligned] [/notraces] [/fault Rate [TimeOut]] [/leaks] [/protect] [/no_sync] [/no_lock_checks]
```

To disable page heap verification:

```
gflags /p [/disable ImageFile] [/?]
```

To display help:

```
gflags /?
```

## Parameters

### Flag

Specifies a three-letter abbreviation (*FlagAbbr*) or hexadecimal value (*FlagHex*) that represents a debugging feature. The abbreviations and hexadecimal values are

listed in the [GFlags Flag Table](#).

Use one of the following flag formats:

| Format                   | Description                                                                                                                                                                                                                                                             |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| {+ -}<br><i>FlagAbbr</i> | Sets (+) or clears (-) the flag represented by the flag abbreviation. Without a plus (+) or minus (-) symbol, the command has no effect.                                                                                                                                |
| [+ -]<br><i>FlagHex</i>  | Adds (+) or subtracts (-) the hexadecimal value of a flag. A flag is set when its value is included in the sum. Add (+) is the default. Enter a hexadecimal value (without 0x) that represents a single flag or enter the sum of hexadecimal values for multiple flags. |

#### *ImageFile*

Specifies the name of an executable file, including the file name extension (for example, notepad.exe or mydll.dll).

#### /r

Registry. Displays or changes system-wide debugging flags stored in the registry. These settings take effect when you restart Windows and remain effective until you change them.

With no additional parameters, **gflags /r** displays the system-wide flags set in the registry.

#### /k

Kernel flag settings. Displays or changes system-wide debugging flags for this session. These settings are effective immediately, but are lost when Windows shuts down. The settings affect processes started after this command completes.

With no additional parameters, **gflags /k** displays system-wide flags set for the current session.

#### /i

Image file settings. Displays or changes debugging flags for a particular process. These settings are stored in the registry. They are effective for all new instances of this process and they remain effective until you change them.

With no additional parameters, **gflags /i ImageFile** displays the flags set for the specified process.

#### /tracedb *SizeInMB*

Sets the maximum size of the user-mode stack trace database for the process. To use this parameter, the [Create user mode stack trace database](#) (ust) flag must be set for the process.

*SizeInMB* is a whole number representing the number of megabytes in decimal units. The default value is the minimum size, 8 MB; there is no maximum size. To revert to the default size, set *SizeInMB* to 0.

#### spp

(Windows Vista and later.) Sets or clears the [Special Pool](#) feature. For an example, see [Example 14: Configuring Special Pool](#).

#### PoolTag

(Windows Vista and later.) Specifies a pool tag for the [Special Pool](#) feature. Use only with the spp flag.

Enter a four-character pattern for *PoolTag*, such as Tag1. It can include the ? (substitute for any single character) and \* (substitute for multiple characters) wildcard characters. For example, Fat\* or Av?4. Pool tags are always case-sensitive.

#### 0xSize

(Windows Vista and later.) Specifies a size range for the Special Pool feature. Use only with the spp flag. For guidance on selecting a size value, see "Selecting an Allocation Size" in [Special Pool](#).

#### /ro

Enables, disables, and displays [Object Reference Tracing](#) settings in the registry. To make a change to this setting effective, you must restart Windows.

Without additional parameters, **/ro** displays the Object Reference Tracing settings in the registry.

To enable Object Reference Tracing, you must include at least one pool tag (**/t PoolTag**) or one image file (**/i ImageFile**) in the command. For details, see [Example 15: Using Object Reference Tracing](#).

The following table lists the subparameters that are valid with **/ro**.

Limits the trace to objects with the specified pool tags. Use a semicolon (;) to separate tag names. Enter up to 16 pool tags.

Enter a four-character pattern for *PoolTags*, such as Tag1.

**/t PoolTags** If you specify more than one pool tag, Windows traces objects with any of the specified pool tags .

If you do not specify any pool tags, Windows traces all objects that are created by the image.

Limits the trace to objects that are created by processes with the specified image file. You can specify only one image file with the **/i** parameter.

**/i** Enter an image file name, such as notepad.exe, with up to 64 characters. "System" and "Idle" are not valid image names.

- ImageFile** If you do not specify an image file, Windows traces all objects with the specified pool tags. If you specify both an image file (**/i**) and one or more pool tags (**/t**), Windows traces objects with any of the specified pool tags that are created by the specified image.
- /d** Clears the Object Reference Tracing feature settings. When used with **/ro**, it clears the settings in the registry.
- /p** Permanent. The trace data is retained until Object Reference Tracing is disabled, or the computer is shut down or restarted. By default, the trace data for an object is discarded when the object is destroyed.

#### /ko

Enables, disables, and displays kernel flag (run time) [Object Reference Tracing](#) settings. Changes to this setting are effective immediately, but are lost when the system is shut down or restarted. For details, see [Example 15: Using Object Reference Tracing](#).

Without additional parameters, **/ko** displays the kernel flag (run time) Object Reference Tracing settings.

To enable Object Reference Tracing, you must include at least one pool tag (**/t PoolTag**) or one image file (**/i ImageFile**) in the command.

The following table lists the subparameters that are valid with **/ko**.

Limits the trace to objects with the specified pool tags. Use a semicolon (;) to separate tag names. Enter up to 16 pool tags.

Enter a four-character pattern for *PoolTags*, such as Tag1.

**/t PoolTags**

If you specify more than one pool tag, Windows traces objects with any of the specified pool tags.

If you do not specify any pool tags, Windows traces all objects that are created by the image.

Limits the trace to objects that are created by processes with the specified image file. You can specify only one image file with the **/i** parameter.

**/i ImageFile**

If you do not specify an image file, Windows traces all objects with the specified pool tags.

If you specify both an image file (**/i**) and one or more pool tags (**/t**), Windows traces objects with any of the specified pool tags that are created by the specified image.

**/d**

Clears the Object Reference Tracing feature settings. When used with **/ro**, it clears the settings in the registry.

**/p**

Permanent. The trace data is retained until Object Reference Tracing is disabled, or the computer is shut down or restarted. By default, the trace data for an object is discarded when the object is destroyed.

#### /p

Sets page heap verification options for a process.

With no additional parameters, **gflags /p** displays a list of image files for which page heap verification is enabled.

Page heap verification monitors dynamic heap memory operations, including allocate operations and free operations, and causes a debugger break when it detects a heap error.

#### /disable ImageFile

Turns off page heap verification (standard or full) for the specified image file.

This command is equivalent to turning off the [Enable page heap](#) (hpa) flag for a process (**gflags /i ImageFile -hpa**). You can use the commands interchangeably.

#### /enable ImageFile

Turns on page heap verification for the specified image file.

By default, the **/enable** parameter turns on *standard* page heap verification for the image file. To enable *full* page heap verification for the image file, add the **/full** parameter to the command or use the **/i** parameter with the **+hpa** flag.

#### /full

Turns on full page heap verification for the process. Full page heap verification places a zone of reserved virtual memory at the end of each allocation.

Using this parameter is equivalent to turning on the [Enable page heap](#) (hpa) flag for a process (**gflags /i ImageFile +hpa**). You can use the commands interchangeably.

#### /backwards

Places the zone of reserved virtual memory at the beginning of an allocation, rather than at the end. As a result, the debugger traps overruns at the beginning of the buffer, instead of those at the end of the buffer. Valid only with the **/full** parameter.

#### /random Probability

Chooses full or standard page heap verification for each allocation, based on the specified probability.

*Probability* is a decimal integer from 0 through 100 representing the probability of full page heap verification. A probability of 100 is the same as using the **/full** parameter. A probability of 0 is the same as using standard page heap verification.

#### /size SizeStart SizeEnd

Enables full page heap verification for allocations within the specified size range and enables standard page heap verification for all other allocations by the process.

*SizeStart* and *SizeEnd* are decimal integers. The default is standard page heap verification for all allocations.

#### /address AddressStart AddressEnd

Enables full page heap verification for memory allocated while a return address in the specified address range is on the run-time call stack. It enables standard page heap verification for all other allocations by the process.

To use this feature, specify a range that includes the addresses of all functions that call the function with the suspect allocation. The address of the calling function will be on the call stack when the suspect allocation occurs.

*AddressStart* and *AddressEnd* specify the address range searched in allocation stack traces. The addresses are specified in hexadecimal format, such as, 0xAABBCCDD.

On Windows Server 2003 and earlier systems, the /address parameter is valid only on x86-based computers. On Windows Vista, it is valid on all supported architectures.

#### /dlls DLL[, DLL...]

Enables full page heap verification for allocations requested by the specified DLLs and standard page heap verification for all other allocations by the process.

*DLL* is the name of a binary file, including its file name extension. The specified file must be a function library that the process loads during execution.

#### /debug

Automatically launches the process specified by the /enable parameter under a debugger.

By default, this parameter uses the NTSD debugger with the command line `ntsd -g -G -x` and with page heap enabled, but you can use the *DebuggerCommand* variable to specify a different debugger and command line.

For information about NTSD, see [Debugging Using CDB and NTSD](#).

This option is useful for programs that are difficult to start from a command prompt and those that are started by other processes.

#### "DebuggerCommand"

Specifies a debugger and the command sent to the debugger. This quoted string can include a fully qualified path to the debugger, the debugger name, and command parameters that the debugger interprets. The quotation marks are required.

If the command includes a path to the debugger, the path cannot contain any other quotation marks. If other quotation marks appear, the command shell (`cmd.exe`) will misinterpret the command.

#### /kdebug

Automatically launches the process specified by the /enable parameter under the NTSD debugger with the command line `ntsd -g -G -x`, with page heap enabled, and with control of NTSD redirected to the kernel debugger.

For information about NTSD, see [Debugging Using CDB and NTSD](#).

#### /unaligned

Aligns the end of each allocation at an end-of-page boundary, even if doing so means that the starting address is not aligned on an 8-byte block. By default, the heap manager guarantees that the starting address of an allocation is aligned on an 8-byte block.

This option is used to detect off-by-one-byte errors. When this parameter is used with the /full parameter, the zone of reserved virtual memory begins just after the last byte of the allocation and an immediate fault occurs when a process tries to read or write even one byte beyond the allocation.

#### /decommit

This option is no longer valid. It is accepted, but ignored.

The PageHeap program (`pageheap.exe`) included in Windows 2000 implemented full page heap verification by placing an inaccessible page after an allocation. In that tool, the /decommit parameter substituted a zone of reserved virtual memory for the inaccessible page. In this version of GFlags, a zone of reserved virtual memory is always used to implement full page heap verification.

#### /notraces

Specifies that run-time stack traces are not saved.

This option improves performance slightly, but it makes debugging much more difficult. This parameter is valid, but its use is not recommended.

#### /fault

Forces the program's memory allocations to fail at the specified rate and after the specified time-out.

This parameter inserts heap allocation errors into the image file being tested (a practice known as "fault injection") so that some memory allocations fail, as might occur when the program runs in low memory conditions. This test helps to detect errors in handling allocation failure, such as failing to release resources.

*Rate*      Specifies a decimal integer from 1 (.01%) through 10000 (100%) representing the probability that an allocation will fail. The default is 100 (1%).  
Determines the time interval between the start of the program and the start of the fault injection routines.

#### *TimeOut*

*TimeOut* is measured in seconds. The default is 5 (seconds).

**/Leaks**

Checks for heap leaks when a process ends.

The **/Leaks** parameter disables full page heap. When **/Leaks** is used, the **/full** parameter and parameters that modify the **/full** parameter, such as **/backwards**, are ignored, and GFlags performs standard page heap verification with a leak check.

**/Protect**

Protects heap internal structures. This test is used to detect random heap corruptions. It can make execution significantly slower.

**/no\_sync**

Checks for unsynchronized access. This parameter causes a break if it detects that a heap created with the HEAP\_NO\_SERIALIZE flag is accessed by different threads.

Do not use this flag to debug a program that includes a customized heap manager. Functions that synchronize heap access cause the page heap verifier to report synchronization faults that do not exist.

**/no\_lock\_checks**

Disables the critical section verifier.

**/?**

Displays help for GFlags. With **/p, /?** displays help for the page heap verification options in GFlags.

**Comments**

Typing **gflags** without parameters opens the **Global Flags** dialog box.

Typing **gflags /p** without additional parameters displays a list of programs that have page heap verification enabled.

To clear all flags, set *Flag* to **-xFFFFFFFF**. (Setting *Flag* to 0 adds zero to the current flag value. It does not clear all flags.)

When you set *Flag* for an image file to **FFFFFFFF**, Windows clears all flags and deletes the GlobalFlag entry in the registry subkey for the image file. The subkey remains.

The **/full, /random, /size, /address, and /dlls** parameters for the page heap **/enable** operation determine which allocations are subject to page heap verification and the verification method used. You can use only one of these parameters in each command. The default is standard page heap verification of all allocations of the process. The remaining parameters set options for page heap verification.

The page heap features in GFlags only monitor heap memory allocations that use the standard Windows heap manager functions (**HeapAlloc**, **GlobalAlloc**, **LocalAlloc**, **malloc**, **new**, **new[]**, or their corresponding deallocation functions), or those that use custom operations that call the standard heap manager functions.

To determine whether full or standard page heap verification is enabled for a program, at the command line, type **gflags /p**. In the resulting display, **traces** indicates that standard page heap verification is enabled for the program and **full traces** indicates that full page heap verification is enabled for the program.

The **/enable** parameter sets the [Enable page heap](#) (hpa) flag for the image file in the registry. However, the **/enable** parameter turns on *standard* heap verification for the image file by default, unlike the **/i** parameter with the **+hpa** flag, which turns on *full* heap verification for an image file.

*Standard* page heap verification places random patterns at the end of an allocation and examines the patterns when a heap block is freed. *Full* page heap verification places a zone of reserved virtual memory at the end of each allocation.

Full page heap verification can consume system memory quickly. To enable full page heap verification for memory-intensive processes, use the **/size** or **/dlls** parameter.

After using global flags for debugging, submit a **gflags /p /disable** command to turn off the page heap verification and delete associated registry entries. Otherwise, entries that the debugger reads remain in the registry. You cannot use the **gflags /i hpa** command for this task, because it turns off page heap verification, but does not delete the registry entries.

By default, on Windows Vista and later versions of Windows, program-specific settings (image file flags and page heap verification settings) are stored in the current user account.

This version of GFlags includes the **-v** options, which enable features being developed for GFlags. However, these features are not yet complete and, therefore, are not documented.

## GFlags Flag Table

The following table lists the flags that GFlags changes, the hexadecimal value and abbreviation for each flag, and the destination (R for registry, K for kernel, I for image file) in which the flag is valid.

For a detailed description of each flag, see the [Global Flag Reference](#).

For information about using GFlags, see [GFlags Overview](#) and [GFlags Details](#).

**Important** Pool tagging is permanently enabled in Windows Server 2003 and later versions of Windows. On these systems, the **Enable pool tagging** check box on the

**Global Flags** dialog box is dimmed, and commands to enable or disable pool tagging fail.

**Note** The symbolic name of each flag is provided for reference only. Because symbolic names change, they are not a reliable identifier of a global flag.

| Description                                                               | Symbolic Name                   | Hexadecimal Value | Abbreviation | Destination                   |

## GFlags and PageHeap

This version of GFlags includes the functionality of PageHeap (pageheap.exe), a tool that enables heap allocation monitoring in Windows. PageHeap enables Windows features that reserve memory at the boundary of each allocation to detect attempts to access memory beyond the allocation.

The page heap options in GFlags let you select *standard heap verification*, which writes fill patterns at the end of each heap allocation and examines the patterns when the allocations are freed, or *full-page heap verification*, which places an inaccessible page at the end of each allocation so that the program stops immediately if it accesses memory beyond the allocation. Because full heap verification uses a full page of memory for each allocation, its widespread use can cause system memory shortages.

- To enable standard page heap verification for all processes, use `gflags /r +hpa` or `gflags /k +hpa`.
- To enable standard page heap verification for one process, use `gflags /p /enable ImageFileName`.
- To enable full page heap verification for one process, use `gflags /i ImageFileName +hpa` or `gflags /p /enable ImageFileName /full`.

All page heap settings, except for /k, are stored in the registry and remain effective until you change them.

Use care in interpreting the **Enable page heap** check box for an image file in the GFlags dialog box. It indicates that page heap verification is enabled for an image file, but it does not indicate whether it is full or standard page heap verification. If the check results from selecting the check box, then full page heap verification is enabled for the

image file. However, if the check results from use of the command-line interface, then the check can represent the enabling of either full or standard page heap verification for the image file.

To determine whether full or standard page heap verification is enabled for a program, at the command line, type **gflags /p**. In the resulting display, **traces** indicates that standard page heap verification is enabled for the program and **full traces** indicates that full page heap verification is enabled for the program.

## Monitoring Silent Process Exit

Beginning with Windows 7, you can use the **Silent Process Exit** tab in GFlags to enter the name of a process that you want to monitor for silent exit.

In the context of this monitoring feature, we use the term *silent exit* to mean that the monitored process terminates in one of the following ways.

Self termination

The monitored process terminates itself by calling **ExitProcess**.

Cross-process termination

A second process terminates the monitored process by calling **TerminateProcess**.

The monitoring feature does not detect normal process termination that happens when the last thread of the process exits. The monitoring feature does not detect process termination that is initiated by kernel-mode code.

To register a process for silent exit monitoring, open the **Silent Process Exit** tab in GFlags. Enter the process name as the **Image** and press the **Tab** key. Check the **Enable Silent Process Exit Monitoring** box, and click **Apply**. This sets the **FLG\_MONITOR\_SILENT\_PROCESS\_EXIT** flag in the following registry entry.

**HKEY\Software\Microsoft\Windows NT\CurrentVersion\Image File Execution Options\ProcessName\GlobalFlag**

For more information about this flag, see [Enable silent process exit monitoring](#).

For more information about using the **Silent Process Exit** tab in GFlags, see [Configuring Silent Process Exit Monitoring](#).

In the **Silent Process Exit** tab of GFlags, you can configure the actions that will take place when a monitored process exits silently. You can configure notification, event logging, and creation of dump files. You can specify a process that will be launched when silent exit is detected, and you can specify a list of modules that the monitor will ignore. Several of these settings are available both globally and for individual applications. Global settings apply to all processes that you register for silent exit monitoring. Application settings apply to an individual process and override global settings.

Global settings are stored in the registry under the following key.

**HKEY\_LOCAL\_MACHINE\Software\Microsoft\Windows NT\CurrentVersion\SilentProcessExit**

Application settings are stored in the registry under the following key.

**HKEY\_LOCAL\_MACHINE\Software\Microsoft\Windows NT\CurrentVersion\SilentProcessExit\ProcessName**

## Reporting Mode

The **Reporting Mode** setting is available as an application setting, but not as a global setting. You can use the following check boxes to set the reporting mode.

- Launch monitor process**
- Enable dump collection**
- Enable notification**

The **ReportingMode** registry entry is a bitwise OR of the following flags.

| Flag                  | Value | Meaning                                                                                                                                                                                            |
|-----------------------|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| LAUNCH_MONITORPROCESS | 0x1   | When silent exit is detected, the monitor process (specified in the <b>Monitor Process</b> box) is launched.                                                                                       |
| LOCAL_DUMP            | 0x2   | When silent exit is detected, a dump file is created for the monitored process. In the case of cross-process termination, a dump file is also created for the process that caused the termination. |
| NOTIFICATION          | 0x4   | When silent exit is detected, a pop-up notification is displayed.                                                                                                                                  |

## Ignore Self Exits

The **Ignore Self Exits** setting is available as an application setting, but not as a global setting. You can use the **Ignore Self Exits** check box to specify whether self exits are ignored.

The **IgnoreSelfExits** registry entry has one of the following values.

| Value | Meaning                                                                    |
|-------|----------------------------------------------------------------------------|
| 0x0   | Detect and respond to both self termination and cross-process termination. |

0x1 Ignore self termination. Detect and respond to cross-process termination.

## Monitor Process

You can specify a monitor process by entering a process name, along with command line parameters, in the **Monitor Process** text box. You can use the following variables in your command line.

| Variable | Meaning                                                                                                                                                                                                      |
|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| %e       | ID of the exiting process. This is the monitored process that exited silently.                                                                                                                               |
| %i       | ID of the initiating process. In the case of self termination, this is the same as the exiting process. In the case of cross-process termination, this is the ID of the process that caused the termination. |
| %t       | ID of the initiating thread. This is the thread that caused the termination.                                                                                                                                 |
| %c       | The status code passed to <b>ExitThread</b> or <b>TerminateThread</b> .                                                                                                                                      |

For example, the following value for **Monitor Process** specifies that on silent exit, WinDbg is launched and attached to the exiting process.

**windbg -p %e**

The **Monitor Process** command line is stored in the **MonitorProcess** registry entry.

## Dump Folder Location

You can use the **Dump folder location** text box to specify a location for the dump files that are written when a silent exit is detected.

The string that you enter for **Dump folder location** is stored in the **LocalDumpFolder** registry entry.

If you do not specify a dump folder location, dump files are written to the default location, which is **%TEMP%\Silent Process Exit**.

## Dump Folder Size

You can use the **Dump folder size** text box to specify the maximum number of dump files that can be written to the dump folder. Enter this value as a decimal integer.

The value that you enter for **Dump folder size** is stored in the **MaximumNumberOfDumpFiles** registry entry.

By default, there is no limit to the number of dump files that can be written.

## Dump Type

You can use the **Dump Type** drop-down list to specify the type of dump file (Micro, Mini, Heap, or Custom) that is written when a silent exit is detected.

The dump type is stored in the **DumpType** registry entry, which is a bitwise OR of the members of the **MINIDUMP\_TYPE** enumeration. This enumeration is defined in **dbghelp.h**, which is included in the Debugging Tools for Windows package.

For example, suppose you chose a dump type of **Micro**, and you see that the **DumpType** registry entry has a value of 0x88. The value 0x88 is a bitwise OR of the following two **MINIDUMP\_TYPE** enumeration values.

MiniDumpFilterModulePaths 0x00000080  
MiniDumpFilterMemory 0x00000008

If you choose a dump type of **Custom**, enter your own bitwise OR of **MINIDUMP\_TYPE** enumeration values in the **Custom Dump Type** box. Enter this value as a decimal integer.

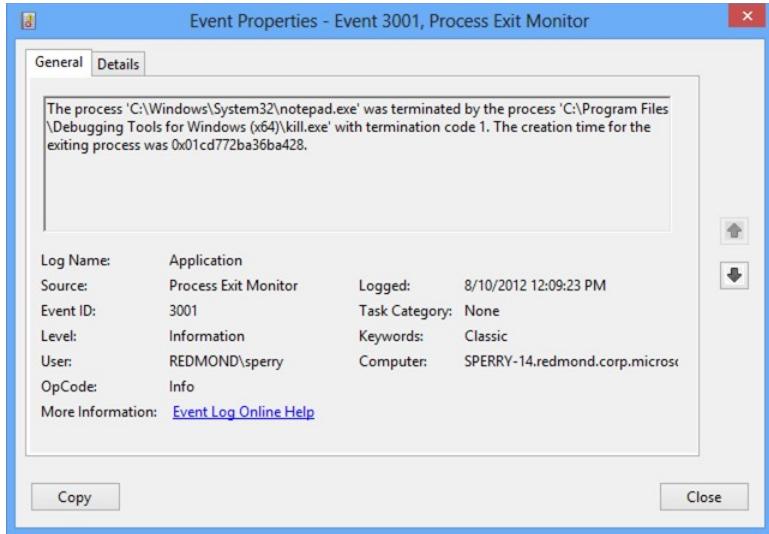

## Module Ignore List

You can use the **Module Ignore List** box to specify a list of modules that will be ignored when a silent exit is detected. If the monitored process is terminated by one of the modules in this list, the silent exit is ignored.

The list of modules that you enter in the **Module Ignore List** box is stored in the **ModuleIgnoreList** registry entry.

## Reading Process Exit Reports in Event Viewer

When a monitored process exits silently, the monitor creates an entry in Event Viewer. To open Event Viewer, enter the command **eventvwr.msc**. Navigate to **Windows Logs > Application**. Look for log entries that have a **Source** of Process Exit Monitor.

## Global Flags Dialog Box

You can use the **Global Flags** dialog box to set and clear global flags from a user interface that lists all flags by name. There is no need to look up flag abbreviations or hexadecimal values.

Also, the dialog box provides access to the following features that are not available from the command line:

- **Debugger** – Specifies that a particular program always runs in a debugger.
- **Launch** – Runs a program with the specified debugging settings.
- **Kernel Special Pool Tag** – Configures the Special Pool feature.

This topic includes instructions for the following procedures:

[Opening the Dialog Box](#)

[Setting and Clearing System-wide Flags](#)

[Setting and Clearing Kernel Flags](#)

[Setting and Clearing Image File Flags](#)

[Launching a Program with Flags](#)

[Running a Program in a Debugger](#)

[Configuring Special Pool](#)

[Configuring Object Reference Tracing](#)

Pool tagging is permanently enabled on Windows Server 2003 and later versions of Windows. On these systems, the **Enable pool tagging** check box on the **Global Flags** dialog box is dimmed, and commands to enable or disable pool tagging fail.

Use care in interpreting the **Enable page heap** check box for an image file in the **Global Flags** dialog box. This check box indicates that page heap verification is enabled for an image file, but it does not indicate whether it is full or standard page heap verification. If the check results from selecting the check box, then full page heap verification is enabled for the image file. However, if the check results from use of the command-line interface, then the check can represent the enabling of either full or standard page heap verification for the image file.

To determine whether a full or standard page heap verification is enabled for a program, at the command line, type **gflags /p**. In the resulting display, **traces** indicates that standard page heap verification is enabled for the program and **full traces** indicates that full page heap verification is enabled for the program.

## Opening the Dialog Box

### To open the Global Flags dialog box

- Double-click the **gflags.exe** icon or, at the command line, or in the **Run** dialog box, type **gflags** (without parameters).
- OR
- Click **Start**, point to **All Programs**, point to **Debugging Tools for Windows**, and then click **Global Flags**.

On Windows Vista, click **Start**, click **All Programs**, click **Debugging Tools for Windows**, right-click **Global Flags** and then click **Run as administrator**. If you omit this step, Windows displays the **System Registry Gflags Error: 5**. The Gflags dialog box opens, but Gflags commands fail.

## Setting and Clearing System-wide Flags

System-wide registry settings affect all processes running on Windows. They are saved in the registry and remain effective until you change them.

### ► To set and clear system-wide registry flags

- Click the **System Registry** tab.

The following screen shot shows the System Registry tab in Windows Vista.

- Set or clear a flag by selecting or clearing the check box associated with the flag.
- When you have selected or cleared all of the flags that you want, click **Apply**.
- Restart Windows to make the changes effective.

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

## Setting and Clearing Kernel Flags

Kernel flag settings, also known as "run-time settings," affect the entire system. They take effect immediately without rebooting, but they are lost if you shut down or restart the system.

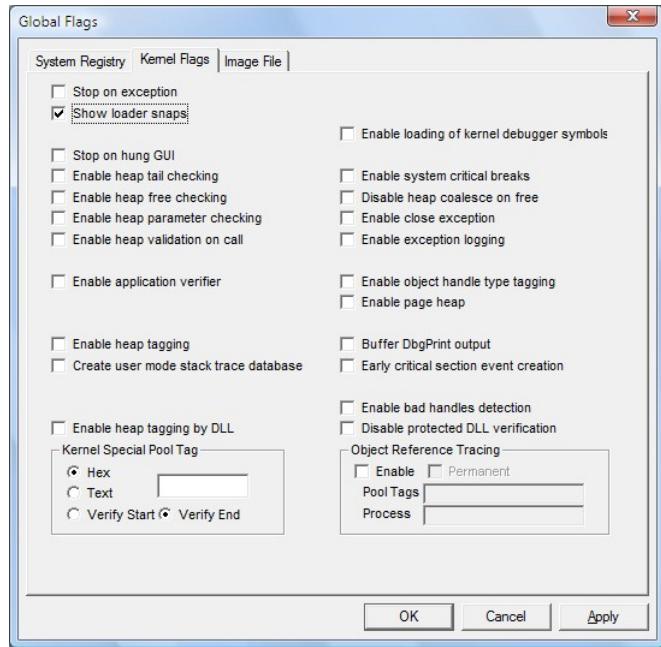

Kernel settings take precedence over registry settings during run time, but when you shut down or restart the system, the kernel flag settings are lost and the registry settings

are effective again.

► To set and clear kernel flags

1. Click the **Kernel Flags** tab.

The following screen shot shows the **Kernel Flags** tab in Windows Vista.

2. Set or clear a flag by selecting or clearing the check box associated with the flag.

3. When you have selected or cleared all of the flags that you want, click **Apply**.

[Send comments about this topic to Microsoft](#)

## Setting and Clearing Image File Flags

Image file settings affect instances of the specified program that start after the command completes. They are saved in the registry and remain effective until you change them.

► To set and clear the image file registry flags

1. Click the **Image File** tab.

The following screen shot shows the **Image File** tab in Windows Vista.

2. In the **Image** box, type the name of an executable file or DLL, including the file name extension, and then press the TAB key.

This activates the check boxes on the **Image File** tab.

3. Set or clear a flag by selecting or clearing the check box associated with the flag.
4. When you have selected or cleared all of the flags you want, click **Apply**.

[Send comments about this topic to Microsoft](#)

## Configuring Silent Process Exit Monitoring

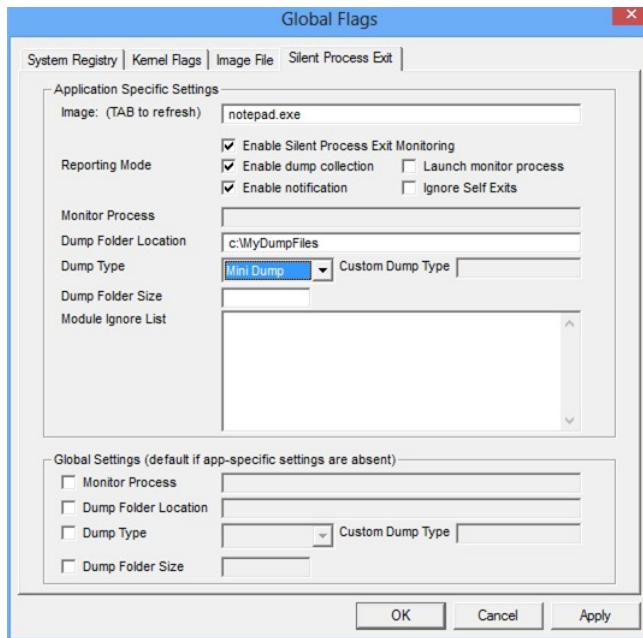

Beginning in Windows 7, you can use the **Silent Process Exit** tab to enable and configure monitoring of silent exit for a process.

Settings that you specify in the **Silent Process Exit** tab are saved in the registry and remain effective until you change them.

### ► To enable and configure silent process exit monitoring

1. Click the **Silent Process Exit** tab.

The following screen shot shows the **Silent Process Exit** tab in Windows 8.

2. In the **Image** box, type the name of an executable file, including the file name extension, and then press the TAB key.

This activates the check boxes on the **Silent Process Exit** tab.

3. Specify your preferences by selecting or clearing check boxes and by entering values in text boxes.
4. When you specified all of your preferences, click **Apply**.

## Launching a Program with Flags

This feature runs a program once with the specified flags. These settings affect only the instance of the program launched. They are not saved in the registry.

### ► To launch a program with flags

1. Click the **Image File** tab.
2. In the **Image** box, type the name of an executable file or DLL, including the file name extension, and any commands for the program, and then press the TAB key.  
This activates the **Launch** button and the check boxes on the **Image File** tab.
3. Set or clear a flag by selecting or clearing the check box associated with the flag.
4. Click the **Launch** button.

The following screen shot shows the **Launch** button on the **Image File** tab in Windows Vista.

**Note** Flags set in the registry do not affect the instance of the program that is launched.

Flags set in the dialog box are used for the launched instance even when they are not image file flags.

## Running a Program in a Debugger

This feature configures the program so that it always runs in a debugger with the specified options. This setting is saved in the registry. It affects all new instances of the program and remains effective until you change it.

### ► To run a program in a debugger

1. Click the **Image File** tab.
2. In the **Image** box, type the name of an executable file or DLL, including the file name extension, and then press the TAB key.  
This activates the check boxes on the **Image File** tab.
3. Click the **Debugger** check box to select it.

The following screen shot shows the **Debugger** check box on the **Image File** tab in Windows Vista.

4. In the **Debugger** box, type the command to run the debugger, including the path (optional) and name of the debugger and parameters. For example, **ntsd -d -g -G -x** or **c:\debuggers\cdb.exe -g -G**.
5. Click **Apply**.

## Configuring Special Pool

The Gflags *Special Pool* feature directs Windows to request memory allocations from a reserved memory pool when the memory is allocated with a specified pool tag or is within a specified size range.

For detailed information about this feature, see [Special Pool](#).

In Windows Vista and later versions of Windows, you can configure the Special Pool feature as a system-wide registry setting or as a kernel flags setting that does not require a reboot. In earlier versions of Windows, Special Pool is available only as a registry setting.

In Windows Vista and later versions of Windows, you can also use the command line to request special pool by pool tag. For information, see [GFlags Commands](#).

This section includes the following topics.

[Requesting Special Pool by Pool Tag](#)

[Requesting Special Pool by Allocation Size](#)

[Canceling Requests for Special Pool](#)

[Detecting Overruns and Underruns](#)

**Note** Use *Driver Verifier* to request special pool for allocations by a particular driver. For more information, see the "Special Pool" topic in the "Driver Verifier" section of the Windows Driver Kit (WDK).

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

## Requesting Special Pool by Pool Tag

You can request special pool for all allocations that use a specified pool tag. Only one pool tag on the system can be associated with kernel special pool requests at one time.

In Windows Vista and later versions of Windows, you can also use the command line to request special pool by pool tag. For information, see [GFlags Commands](#).

#### ► To request special pool by pool tag

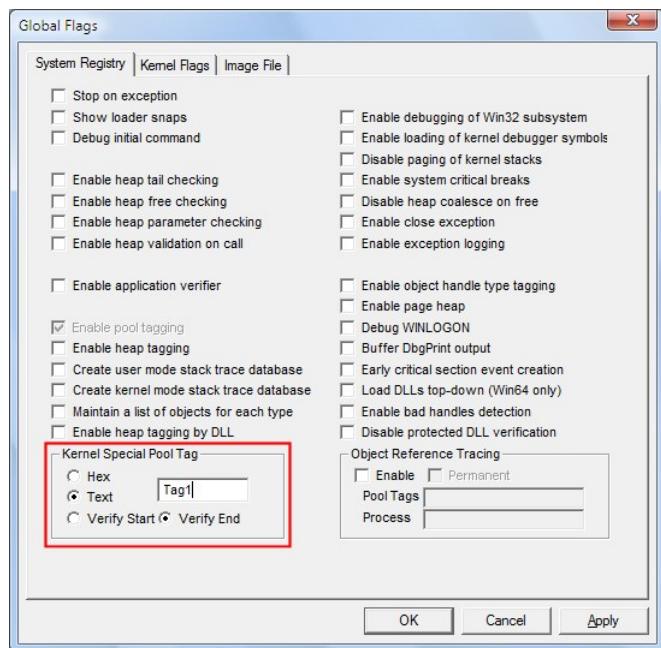

1. Select the **System Registry** tab or the **Kernel Flags** tab.

On Windows Vista and later versions of Windows, this option is available on both tabs. On earlier versions of Windows, it is available only on the **System Registry** tab.

2. In the **Kernel Special Pool Tag** section, click **Text**, and then type a four-character pattern for the tag.

The tag can include the ? (single character) and \* (multiple characters) wildcard characters. For example, Fat\* or Av?4.

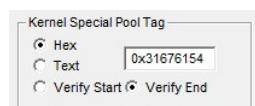

3. The following screen shot shows a tag entered as text on the System Registry tab.

4. Click **Apply**.

When you click **Apply**, GFlags changes the selection from **Text** to **Hex** and displays the ASCII characters as hexadecimal values in reverse (lower endian) order. For example, if you type **Tag1**, GFlags displays the tag as **0x31676154** (1gaT). This is the way that it is stored in the registry and displayed by the debugger and other tools.

The following illustration shows the effect of clicking **Apply**.

#### Remarks

To use this feature effectively, make sure that your driver or other kernel-mode program uses a unique pool tag. If you suspect that your driver is consuming all of the special pool, consider using multiple pool tags in your code. You can then test your driver several times, assigning special pool to one pool tag in each test.

Also, select a pool tag with a hexadecimal value that is greater than the page size of the system. For kernel mode code, if you enter a pool tag that has a value less than PAGE\_SIZE, GFlags requests special pool for all allocations whose size is within the corresponding range and requests special pool for allocations with an equivalent pool tag. For example, if you select a size of **30**, special pool will be used for all allocations between 17 and 32 bytes in size, and for allocations with the pool tag **0x0030**.

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

## Requesting Special Pool by Allocation Size

You can request special pool for allocations within a specified size range.

In Windows Vista and later versions of Windows, you can also use the command line to request special pool by pool tag. For information, see [GFlags Commands](#).

**Note** This method is rarely useful for diagnosing driver errors, because it affects all kernel pool requests of the specified size, regardless of which driver or kernel module requested the allocation.

### To request special pool by allocation size

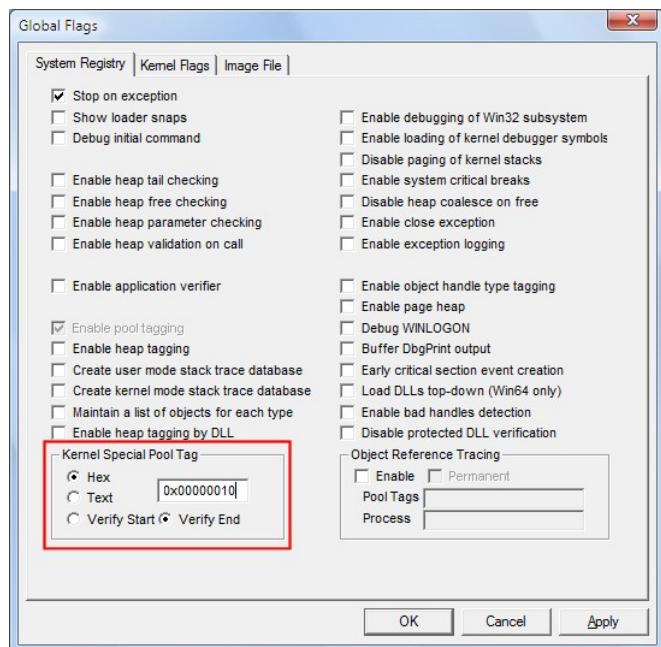

1. Select the **System Registry** tab or the **Kernel Flags** tab.

On Windows Vista and later versions of Windows, this option is available on both tabs. On earlier versions of Windows, it is available only on the **System Registry** tab.

2. In the **Kernel Special Pool Tag** section, click **Hex**, and then type a number in hexadecimal format that represents a range of sizes. All allocations within this size range will be allocated from special pool. This number must be less than PAGE\_SIZE.

3. Click **Apply**.

The following screen shot shows an allocation size entered as a hexadecimal value.

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

## Canceling Requests for Special Pool

You can use GFlags to cancel a request for allocation from the special pool if the request was made by using GFlags. You cannot use GFlags to cancel a request for special pool that was made by using Driver Verifier.

In Windows Vista and later versions of Windows, you can also use the command line to cancel special pool requests. For information, see [GFlags Commands](#).

### ► To cancel requests for special pool

1. Select the System Registry tab or the Kernel Flags tab.

On Windows Vista and later versions of Windows, this option is available on both tabs. On earlier versions of Windows, it is available only on the **System Registry** tab.

2. Delete the text or hexadecimal value from the **Kernel Special Pool Tag** box.

3. Click **Apply**.

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

## Detecting Overruns and Underruns

You can use the **Verify Start** or **Verify End** option in GFlags to align allocations from the special pool so that they are best suited to detect overruns (accessing memory past the end of the allocation) or underruns (accessing memory that precedes the beginning of the allocation).

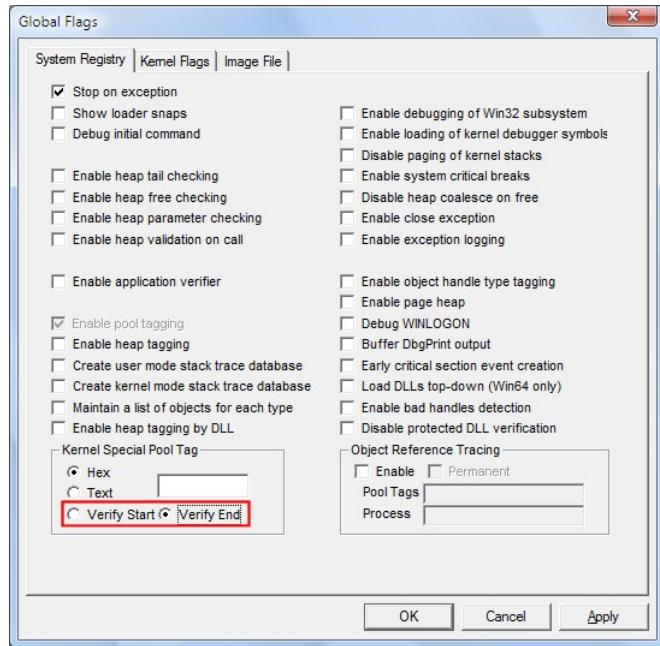

- **Verify Start** enables underrun detection on allocations from the special pool. This causes a bug check when a program tries to access memory preceding its special pool memory allocation.
- **Verify End** enables overrun detection on allocations from the special pool. This causes a bug check when a program tries to access memory beyond its special pool memory allocation. Because overruns are much more common, **Verify End** is the default.

In Windows Vista and later versions of Windows, this option is available on the **System Registry** and **Kernel Flags** tabs. In earlier versions of Windows, it is available only on the **System Registry** tab.

### ► To specify special pool alignment

1. Click the **System Registry** tab.
2. Click **Verify Start** or **Verify End**.
3. Click **Apply**.

The following screen shot shows the Verify Start and Verify End settings on the System Registry tab.

### Comments

The **Verify Start** and **Verify End** alignment settings apply to all allocations from the special pool, including special pool allocation requests set in Driver Verifier. If you set the alignment without specifying a pool tag or allocation size, then the settings apply only to requests set in Driver Verifier.

[Send comments about this topic to Microsoft](#)

## Configuring Object Reference Tracing

You can use Gflags to enable, disable, and configure the Object Reference Tracing feature of Windows. Object Reference Tracing records sequential stack traces whenever an object reference counter is incremented or decremented. The traces can help you to detect object reference errors, including double-dereferencing, failure to reference, and failure to dereference objects. This feature is supported only in Windows Vista and later versions of Windows. For detailed information about this feature, see [Object Reference Tracing](#).

### ► To enable Object Reference Tracing

1. In the Gflags dialog box, select the **System Registry** tab or the **Kernel Flags** tab.
2. In the Object Reference Tracing section, select **Enable**.

You must limit the trace to objects with specified pool tags, to objects created by a specified process, or both.

- To limit the trace to objects with a particular pool tag, type the pool tag name. To list multiple pool tags, use semicolons (;) to separate the pool tags. When you list multiple pool tags, the trace includes objects with any of the specified pool tags. Pool tags are case sensitive.

For example, Fred;Tag1.

- To limit the trace to objects that are created by a particular process, type the image name of the process. You can specify only one image file name.

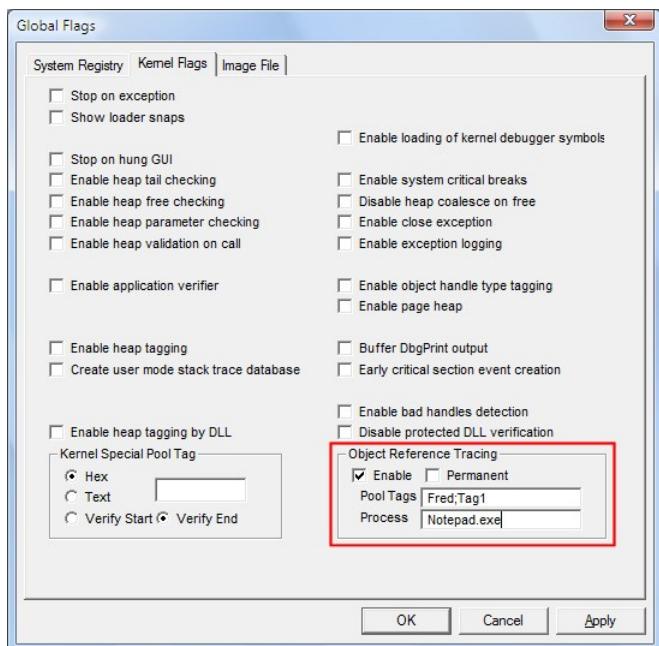

When you specify both pool tags and a process, the trace includes objects that are created by the process that have any of the specified pool tags.

- To retain the trace after the trace object is destroyed, select **Permanent**.

When you select **Permanent**, the trace is retained until you disable object reference tracing, or shut down or restart Windows.

- Click **Apply** or **OK**.

The following screen shot shows Object Reference Tracing enabled on the **Kernel Flags** tab.

This trace will include only objects that were created by the notepad.exe process that have the pool tag **Fred** or **Tag1**. Because this is a run time (kernel flags) setting, the trace starts immediately. If it were a registry setting, you would have to restart Windows to start the trace.

#### ► To disable Object Reference Tracing

- In the Gflags dialog box, select the **System Registry** tab or the **Kernel Flags** tab. Object Reference Tracing will appear on the latter tab only in Windows Vista and later versions of Windows.
- In the Object Reference Tracing section, clear the **Enable** check box.

## Global Flag Reference

This reference describes the flags that GFlags sets.

**Note** The symbolic name of each flag is provided for reference only. Because symbolic names change, they are not a reliable identifier of a global flag.

The global flags include:

[Buffer DbgPrint Output](#)

[Create kernel mode stack trace database](#)

[Create user mode stack trace database](#)

[Debug initial command](#)  
[Debug WinLogon](#)  
[Disable heap coalesce on free](#)  
[Disable paging of kernel stacks](#)  
[Disable protected DLL verification](#)  
[Disable stack extension](#)  
[Early critical section event creation](#)  
[Enable application verifier](#)  
[Enable bad handles detection](#)  
[Enable close exception](#)  
[Enable debugging of Win32 subsystem](#)  
[Enable exception logging](#)  
[Enable heap free checking](#)  
[Enable heap tagging](#)  
[Enable heap tagging by DLL](#)  
[Enable heap tail checking](#)  
[Enable heap validation on call](#)  
[Enable loading of kernel debugger symbols](#)  
[Enable object handle type tagging](#)  
[Enable page heap](#)  
[Enable pool tagging](#)  
[Enable system critical breaks](#)  
[Load image using large pages if possible](#)  
[Maintain a list of objects for each type](#)  
[Object Reference Tracing](#)  
[Show loader snaps](#)  
[Special Pool](#)  
[Stop on exception](#)  
[Stop on hung GUI](#)  
[Stop on unhandled user-mode exception](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

## Buffer DbgPrint Output

The **Buffer DbgPrint Output** flag suppresses debugger output from **DbgPrint**, **DbgPrintEx**, **KdPrint**, and **KdPrintEx** calls.

**Abbreviation** ddp  
**Hexadecimal value** 0x08000000  
**Symbolic Name** FLG\_DISABLE\_DBGPRINT  
**Destination** System-wide registry entry, kernel flag

### Comments

When debugger output is suppressed, it does not automatically appear in the kernel debugger. However, the message is always sent to the DbgPrint buffer, where it can be accessed by using the [!dbgprint](#) debugger extension.

For information about the functions that communicate with the debugger, see [Sending Output to the Debugger](#).

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

## Create kernel mode stack trace database

The **Create kernel mode stack trace database** flag creates a run-time stack trace database of kernel operations, such as resource objects and object management operations, and works only when using the checked build of Windows.

|                          |                            |
|--------------------------|----------------------------|
| <b>Abbreviation</b>      | ks                         |
| <b>Hexadecimal value</b> | 0x2000                     |
| <b>Symbolic Name</b>     | FLG_KERNEL_STACK_TRACE_DB  |
| <b>Destination</b>       | System-wide registry entry |

### Comments

GFlags displays this flag as a kernel flag setting, but it is not effective at run time, because the kernel is already started.

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

## Create user mode stack trace database

The **Create user mode stack trace database** flag creates a run-time stack trace database in the address space of a particular process (image file mode) or all processes (system-wide).

|                          |                                                                    |
|--------------------------|--------------------------------------------------------------------|
| <b>Abbreviation</b>      | ust                                                                |
| <b>Hexadecimal value</b> | 0x1000                                                             |
| <b>Symbolic Name</b>     | FLG_USER_STACK_TRACE_DB                                            |
| <b>Destination</b>       | System-wide registry entry, kernel flag, image file registry entry |

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

## Debug initial command

The **Debug initial command** flag debugs the Client Server Run-time Subsystem (CSRSS) and the WinLogon process.

|                          |                                         |
|--------------------------|-----------------------------------------|
| <b>Abbreviation</b>      | dic                                     |
| <b>Hexadecimal value</b> | 0x4                                     |
| <b>Symbolic Name</b>     | FLG_DEBUG_INITIAL_COMMAND               |
| <b>Destination</b>       | System-wide registry entry, kernel flag |

### Comments

NTSD debugs the processes (using the command **ntsd -d**), but control is redirected to the kernel debugger.

For details on NTSD, see [Debugging Using CDB and NTSD](#).

### See Also

[Enable debugging of Win32 subsystem](#)

[Send comments about this topic to Microsoft](#)

## Debug WinLogon

The **Debug WinLogon** flag debugs the WinLogon service.

|                          |                              |
|--------------------------|------------------------------|
| <b>Abbreviation</b>      | dwl                          |
| <b>Hexadecimal value</b> | 0x04000000                   |
| <b>Symbolic Name</b>     | FLG_DEBUG_INITIAL_COMMAND_EX |
| <b>Destination</b>       | System-wide registry entry   |

### Comments

NTSD debugs Winlogon (by using the command **ntsd -d -g -x**), but control is redirected to the kernel debugger.

For details on NTSD, see [Debugging Using CDB and NTSD](#).

## Disable heap coalesce on free

The **Disable heap coalesce on free** flag leaves adjacent blocks of heap memory separate when they are freed.

|                          |                                                                    |
|--------------------------|--------------------------------------------------------------------|
| <b>Abbreviation</b>      | dhc                                                                |
| <b>Hexadecimal value</b> | 0x00200000                                                         |
| <b>Symbolic Name</b>     | FLG_HEAP_DISABLE_COALESCING                                        |
| <b>Destination</b>       | System-wide registry entry, kernel flag, image file registry entry |

### Comments

By default, Windows combines ("coalesces") newly-freed adjacent blocks into a single block. Combining the blocks takes time, but reduces fragmentation that might force the heap to allocate additional memory when it cannot find contiguous memory.

This flag is used for maintaining compatibility with old applications.

## Disable paging of kernel stacks

The **Disable paging of kernel stacks** flag prevents paging of the kernel-mode stacks of inactive threads.

|                          |                                |
|--------------------------|--------------------------------|
| <b>Abbreviation</b>      | dps                            |
| <b>Hexadecimal value</b> | 0x80000                        |
| <b>Symbolic Name</b>     | FLG_DISABLE_PAGE_KERNEL_STACKS |
| <b>Destination</b>       | System-wide registry entry     |

### Comments

Generally, the kernel-mode stack cannot be paged; it is guaranteed to be resident in memory. However, Windows occasionally pages the kernel stacks of inactive threads. This

flag prevents these occurrences.

The kernel debugger can provide information about a thread only when its stack is in physical memory. This flag is particularly important when debugging deadlocks and in other cases when every thread must be tracked.

[Send comments about this topic to Microsoft](#)

## Disable protected DLL verification

The **Disable protected DLL verification** flag appears in GFlags, but it has no effect on Windows.

**Abbreviation** dpd

**Hexadecimal value** 0x80000000

**Symbolic Name** FLG\_DISABLE\_PROTDLLS

**Destination** System-wide registry entry, kernel flag, image file registry entry

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

## Disable stack extension

The **Disable stack extension** flag prevents the kernel from extending the stacks of the threads in the process beyond the initial committed memory.

**Abbreviation** dse

**Hexadecimal value** 0x10000

**Symbolic Name** FLG\_DISABLE\_STACK\_EXTENSION

**Destination** Image file registry entry

### Comments

This feature is used to simulate low memory conditions (where stack extensions fail) and to test the strategic system processes that are expected to run well even with low memory.

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

## Early critical section event creation

The **Early critical section event creation** flag creates event handles when a critical section is initialized, rather than waiting until the event is needed.

**Abbreviation** cse

**Hexadecimal value** 0x10000000

**Symbolic Name** FLG\_CRITSEC\_EVENT\_CREATION

**Destination** System-wide registry entry, kernel flag, image file registry entry

### Comments

When Windows cannot create an event, it generates the exception during initialization and the calls to enter and leave the critical section do not fail.

Because this flag uses a significant amount of nonpaged pool memory, use it only on very reliable systems that have sufficient memory.

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

## Enable application verifier

The **Enable application verifier** flag enables system features that are used for user-mode application testing, such as page heap verification, lock checks, and handle checks.

**Abbreviation** vrf

**Hexadecimal value** 0x100

**Symbolic Name** FLG\_APPLICATION\_VERIFIER

**Destination** System-wide registry entry, kernel flag, image file registry entry

### Comments

This flag enables only the most basic detection features. To test user-mode applications reliably, use Application Verifier (appverif.exe). For more information, see [Application Verifier](#).

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

## Enable bad handles detection

The **Enable bad handles detection** flag raises a user-mode exception (STATUS\_INVALID\_HANDLE) whenever a user-mode process passes an invalid handle to the Object Manager.

**Abbreviation** bhd

**Hexadecimal value** 0x40000000

**Symbolic Name** FLG\_ENABLE\_HANDLE\_EXCEPTIONS

**Destination** System-wide registry entry, kernel flag

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

## Enable close exception

The **Enable close exception** flag raises a user-mode exception whenever an invalid handle is passed to the **CloseHandle** interface or related interfaces, such as **SetEvent**, that take handles as arguments.

**Abbreviation** ece

**Hexadecimal value** 0x00400000

**Symbolic Name** FLG\_ENABLE\_CLOSE\_EXCEPTIONS

**Destination** System-wide registry entry, kernel flag

**Note** This flag is still supported, but the [Enable bad handles detection](#) flag (bhd), which performs a more comprehensive check of handle use, is preferred.

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

## Enable debugging of Win32 subsystem

The **Enable debugging of Win32 subsystem** flag debugs the Client Server Run-time Subsystem (csrss.exe) in the NTSD debugger.

**Abbreviation** d32

**Hexadecimal value** 0x20000  
**Symbolic Name** FLG\_ENABLE\_CSRDEBUG  
**Destination** System-wide registry entry

### Comments

NTSD debugs the process by using the command **ntsd -d -p -1**.

This flag is effective only when the [Debug initial command](#) flag (dic) or the [Debug WinLogon](#) flag (dwl) is also set.

For details on NTSD, see [Debugging Using CDB and NTSD](#).

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

## Enable exception logging

The **Enable exception logging** flag creates a log of exception records in the kernel run-time library. You can access the log from a kernel debugger.

**Abbreviation** eel  
**Hexadecimal value** 0x00800000  
**Symbolic Name** FLG\_ENABLE\_EXCEPTION\_LOGGING  
**Destination** System-wide registry entry, kernel flag

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

## Enable heap free checking

The **Enable heap free checking** flag validates each heap allocation when it is freed.

**Abbreviation** hfc  
**Hexadecimal value** 0x20  
**Symbolic Name** FLG\_HEAP\_ENABLE\_FREE\_CHECK  
**Destination** System-wide registry entry, kernel flag, image file registry entry

### See Also

[Enable heap tail checking](#), [Enable heap parameter checking](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

## Enable heap parameter checking

The **Enable heap parameter checking** flag verifies selected aspects of the heap whenever a heap function is called.

**Abbreviation** hpc  
**Hexadecimal value** 0x40  
**Symbolic Name** FLG\_HEAP\_VALIDATE\_PARAMETERS  
**Destination** System-wide registry entry, kernel flag, image file registry entry

### See Also

[Enable heap validation on call](#)[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

## Enable heap tagging

The **Enable heap tagging** flag assigns unique tags to heap allocations.

**Abbreviation** htg**Hexadecimal value** 0x800**Symbolic Name** FLG\_HEAP\_ENABLE\_TAGGING**Destination** System-wide registry entry, kernel flag, image file registry entry

### Comments

You can display the tag by using the [!heap](#) debugger extension with the -t parameter.

### See Also

[Enable heap tagging by DLL](#)[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

## Enable heap tagging by DLL

The **Enable heap tagging by DLL** flag assigns a unique tag to heap allocations created by the same DLL.

**Abbreviation** htd**Hexadecimal value** 0x8000**Symbolic Name** FLG\_HEAP\_ENABLE\_TAG\_BY\_DLL**Destination** System-wide registry entry, kernel flag, image file registry entry

### Comments

You can display the tag by using the [!heap](#) debugger extension with the -t parameter.

### See Also

[Enable heap tagging](#)[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

## Enable heap tail checking

The **Enable heap tail checking** flag checks for buffer overruns when the heap is freed.

**Abbreviation** htc**Hexadecimal value** 0x10**Symbolic Name** FLG\_HEAP\_ENABLE\_TAIL\_CHECK**Destination** System-wide registry entry, kernel flag, image file registry entry

### Comments

This flag adds a short pattern to the end of each allocation. The Windows heap manager detects the pattern when the block is freed and, if the block was modified, the heap manager breaks into the debugger.

#### See Also

[Enable heap free checking](#), [Enable heap parameter checking](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

## Enable heap validation on call

The **Enable heap validation on call** flag validates the entire heap each time a heap function is called.

**Abbreviation** hvc

**Hexadecimal value** 0x80

**Symbolic Name** FLG\_HEAP\_VALIDATE\_ALL

**Destination** System-wide registry entry, kernel flag, image file registry entry

#### Comments

To avoid the high overhead associated with this flag, use the **HeapValidate** function instead of setting this flag, especially at critical junctures, such as when the heap is destroyed. However, this flag is useful for detecting random corruption in a pool.

#### See Also

[Enable heap parameter checking](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

## Enable loading of kernel debugger symbols

The **Enable loading of kernel debugger symbols** flag loads kernel symbols into the kernel memory space the next time Windows starts.

**Abbreviation** ksl

**Hexadecimal value** 0x40000

**Symbolic Name** FLG\_ENABLE\_KDEBUG\_SYMBOL\_LOAD

**Destination** System-wide registry entry, kernel flag

#### Comments

The kernel symbols are used in kernel profiling and by advanced kernel debugging tools.

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

## Enable object handle type tagging

The **Enable object handle type tagging** flag appears in GFlags, but it has no effect on Windows.

**Abbreviation** eot

**Hexadecimal value** 0x01000000

**Symbolic Name** FLG\_ENABLE\_HANDLE\_TYPE\_TAGGING

**Destination** System-wide registry entry, kernel flag

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

## Enable page heap

The **Enable page heap** flag turns on page heap verification, which monitors dynamic heap memory operations, including allocate and free operations, and causes a debugger break when the verifier detects a heap error.

**Abbreviation** hpa

**Hexadecimal value** 0x02000000

**Symbolic Name** FLG\_HEAP\_PAGE\_ALLOCS

**Destination** System-wide registry entry, kernel flag, image file registry entry

### Comments

This option enables full page heap verification when set for image files and standard page heap verification when set in the system registry or as a kernel flag.

- *Full page heap verification* (for /i) places a zone of reserved virtual memory at the end of each allocation.
- *Standard page heap verification* (for /r or /k) places random patterns at the end of an allocation and examines the patterns when a heap block is freed.

Setting this flag for an image file is the same as typing **gflags /p /enable ImageFile /full** for the image file at the command line.

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

## Enable pool tagging

The **Enable pool tagging** flag collects data and calculates statistics about pool memory allocations sorted by pool tag value.

**Abbreviation** ptg

**Hexadecimal value** 0x400

**Symbolic Name** FLG\_POOL\_ENABLE\_TAGGING

**Destination** System-wide registry entry

### Comments

This flag is permanently set in Windows Server 2003 and later versions of Windows. On these systems, the **Enable pool tagging** check box in the Global Flags dialog box is dimmed and commands to enable or disable pool tagging fail.

Use **ExAllocatePoolWithTag** or **ExAllocatePoolWithQuotaTag** to set the tag value. When no tag value is specified (**ExAllocatePool**, **ExAllocatePoolWithTag**), Windows creates a tag with the default value of "None." Because data for all allocations with a "None" tag is combined, you cannot distinguish the data for a specific allocation. For information about these routines, see the Windows Driver Kit (WDK).

In Windows XP and earlier systems, this flag also directs Windows to attach a pool tag even when the pool memory is allocated by using **ExAllocatePoolWithQuotaTag**. Otherwise, the tag bytes are used to store the quota values. In Windows Server 2003, tag values and quota values are stored in separate fields that are attached to every pool memory allocation.

**Note** To display the data that Windows collects about a tagged allocation, use PoolMon, a tool that is included in the Windows Driver Kit.

The description of the **Enable Pool Tagging** flag in the Windows XP Support Tools documentation is incomplete. This flag directs Windows to collect and process data by tag value.

[Send comments about this topic to Microsoft](#)

## Enable silent process exit monitoring

The **Enable silent process exit monitoring** flag enables silent exit monitoring for a process.

**Hexadecimal value** 0x200

**Symbolic Name** FLG\_MONITOR\_SILENT\_PROCESS\_EXIT  
**Destination** Image file registry entry

#### Comments

For more information about monitoring a process for silent exit, see [Monitoring Silent Process Exit](#).

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

## Enable system critical breaks

The **Enable system critical breaks** flag forces a system break into the debugger.

**Abbreviation** scb

**Hexadecimal value** 0x100000

**Symbolic Name** FLG\_ENABLE\_SYSTEM\_CRIT\_BREAKS  
**Destination** System-wide registry entry, kernel flag, image file registry entry

#### Comments

When set for a process (image file), this flag forces a system break into the debugger whenever the specified process stops abnormally. This flag is effective only when the process calls the **RtlSetProcessBreakOnExit** and **RtlSetThreadBreakOnExit** interfaces.

When set system-wide (registry or kernel flag), this flag forces a system break into the debugger whenever processes that have called the **RtlSetProcessBreakOnExit** and **RtlSetThreadBreakOnExit** interfaces stop abnormally.

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

## Load image using large pages if possible

The **Load image using large pages if possible** setting directs the system to use large pages (4 MB) rather than the standard small pages (4 KB) when mapping binaries into the process address space.

This setting is most helpful for large executable files, because it significantly reduces the number of page table entries in physical memory.

**Abbreviation** lpg

**Hexadecimal value** (none)

**Symbolic Name**

**Destination** Image file registry entry

#### Comments

This setting is not technically a global flag, because its value is stored in a separate registry entry, not as a value of the GlobalFlag registry entry. As a result, you cannot set it by using a hexadecimal value, and when you select this setting for an image file, it appears in the **Other settings** field of the display.

[Send comments about this topic to Microsoft](#)

## Maintain a list of objects for each type

The **Maintain a list of objects for each type** flag collects and maintains a list of active objects by object type, for example, event, mutex, and semaphore.

|                          |                              |
|--------------------------|------------------------------|
| <b>Abbreviation</b>      | otl                          |
| <b>Hexadecimal value</b> | 0x4000                       |
| <b>Symbolic Name</b>     | FLG_MAINTAIN_OBJECT_TYPELIST |
| <b>Destination</b>       | System-wide registry entry   |

## Comments

To display the object list, use Open Handles (oh.exe), a tool included in the Windows 2000 Resource Kit, and now available for download from the [Microsoft Windows 2000 Resource Kit](#) Web site. Because Open Handles automatically sets the OTL flag, but does not clear it, use **GFlags -otl** to clear the flag.

**Note** The linked lists created when you set this flag use eight bytes of overhead for each object. Remember to clear this flag when your analysis is complete.

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

## Object Reference Tracing

The **Object Reference Tracing** feature records sequential stack traces each time that an object reference counter is incremented or decremented. The traces can help you to detect object reference errors, including double-dereferencing, failure to reference, and failure to dereference objects. This feature is supported only in Windows Vista and later versions of Windows.

For information about configuring the Object Reference Tracing feature in the **Global Flags** dialog box, see [Configuring Object Reference Tracing](#). For information about configuring the Object Reference Tracing feature at the command prompt, see [GFlags Commands](#). For an example, see [Example 15: Using Object Reference Tracing](#).

Object reference traces are most useful when you suspect that a particular object is not being referenced or dereferenced properly, typically because increased pool usage indicates that an object is leaking, or a process or session cannot be ended, even though its handle count is zero. Unlike traces that are recorded in logs for later review, object reference traces are designed to be used in real time, while the process is running and the object is being referenced and dereferenced. You view an object reference trace in the debugger by using the [!objtrace debugger extension](#). Because this extension requires a specified object address, you must know in advance which object is the likely source of the error.

The following rules apply to Object Reference Tracing:

- You can run only one object reference trace at a time.
- Because a kernel-wide trace is not practical, you must limit the trace to objects that are created with specified pool tags, or to objects that are created by a specified process (indicated by an image file name), or both.
- You can specify only one image file for each trace. If you specify an image file, the trace is limited to objects that are created by the processes that the image represents. Objects that are referenced by the process, but are created by a different process, are not traced.
- You can specify a maximum of 16 pool tags for each trace. Objects with any of the specified pool tags are traced.
- If you specify both an image file and one or more pool tags, the trace is limited to objects that are created by the process and have any of the specified pool tags.
- Object Reference Tracing cannot trace processes that are already running when a trace is started. The trace includes only the objects of processes that start after the trace begins.
- Objects marked for tracing are traced until the object is destroyed or tracing is disabled. By default, the traces for an object are maintained only until the object is destroyed, but you can specify a "permanent" trace (/p) where the trace is retained until tracing is disabled.
- You can store the Object Reference Tracing configuration as a registry setting or a kernel flag (run-time) setting. If you have both registry and kernel flag settings, the run-time settings take precedence, but are lost when you shut down or restart the computer.

## Show loader snaps

The **Show loader snaps** flag captures detailed information about the loading and unloading of executable images and their supporting library modules and displays the data in the kernel debugger console.

|                          |                                                                    |
|--------------------------|--------------------------------------------------------------------|
| <b>Abbreviation</b>      | sls                                                                |
| <b>Hexadecimal value</b> | 0x2                                                                |
| <b>Symbolic Name</b>     | FLG_SHOW_LDR_SNAPS                                                 |
| <b>Destination</b>       | System-wide registry entry, kernel flag, image file registry entry |

## Comments

For system-wide (registry or kernel flag), this flag displays information about driver loading and unloading operations.

For per-process (image file), this flag displays information about loading and unloading of DLLs.

[Send comments about this topic to Microsoft](#)

## Special Pool

The **Special Pool** feature configures Windows to request memory allocations from a reserved memory pool when the memory is allocated with a specified pool tag or is within a specified size range.

|                          |                                                                   |
|--------------------------|-------------------------------------------------------------------|
| <b>Abbreviation</b>      | spp                                                               |
| <b>Hexadecimal value</b> | (None)                                                            |
| <b>Symbolic Name</b>     | (None)                                                            |
|                          | System-wide registry entry                                        |
| <b>Destination</b>       | (Windows Vista and later) System-wide registry entry, kernel flag |

### Selecting a Pool Tag

When requesting special pool for a particular pool tag, make sure that your driver or other kernel-mode program uses a unique pool tag.

Also, when creating a pool tag (such as by using [ExAllocatePoolWithTag](#)), consider entering the tag characters in reverse order. For example, if the tag is **Fred**, consider entering it as **derF** (0x4657246). Pool tags are stored in the registry and displayed in the debugger and other tools in reverse (lower endian) order. If you enter them in reverse order, they are displayed in forward order (0x46726564).

If you suspect that your driver is consuming all of the special pool, consider using multiple pool tags in your code. You can then test your driver several times, assigning special pool to one pool tag in each test.

Also, select a pool tag with a hexadecimal value that is greater than the page size of the system. For kernel mode code, if you enter a pool tag that has a value less than PAGE\_SIZE, Gflags requests special pool for all allocations whose size is within the corresponding range and requests special pool for allocations with an equivalent pool tag. For example, if you select a size of **30**, special pool will be used for all allocations between 17 and 32 bytes in size, and for allocations with the pool tag 0x0030.

### Selecting an Allocation Size

Use the following guidelines to select an allocation size for the Special Pool feature.

On a computer with an x86 processor, PAGE\_SIZE is 0x1000 and the allocation size ranges are 8 bytes in length. To configure the Special Pool feature for all allocations with sizes in this range, enter a number equal to the maximum of this range plus 8. (This number is always a multiple of 8.) The following table illustrates these values:

| Size range           | Enter this number  |
|----------------------|--------------------|
| 1 to 8 bytes         | 10 (decimal 16)    |
| 9 to 16 bytes        | 18 (decimal 24)    |
| 17 to 24 bytes       | 20 (decimal 32)    |
| ...                  | ...                |
| 0xFE9 to 0xFF0 bytes | FF8 (decimal 4088) |

On a computer with an AMD x86-64 processor, PAGE\_SIZE is 0x1000 and the allocation size ranges are 16 bytes in length. To configure the Special Pool feature for all allocations with sizes in this range, enter a number equal to the maximum of this range plus 16. (This number is always a multiple of 16.) The following table illustrates these values:

| Size range           | Enter this number  |
|----------------------|--------------------|
| 1 to 16 bytes        | 20 (decimal 32)    |
| 17 to 32 bytes       | 30 (decimal 48)    |
| 33 to 48 bytes       | 40 (decimal 64)    |
| ...                  | ...                |
| 0xFD1 to 0xFE0 bytes | FF0 (decimal 4080) |

On a computer with any processor, you can use an asterisk (\*) or 0x2A (decimal 42) to configure the Special Pool feature for all memory allocations on the system.

## Comments

For information about configuring the Special Pool feature in the Global Flags Dialog Box, see [Configuring Special Pool](#). For information about configuring the Special Pool feature at the command line, see [GFlags Commands](#). For an example, see [Example 14: Configuring Special Pool](#).

The Special Pool feature of Gflags directs Windows to request memory allocations from a reserved memory pool when the memory is allocated with a specified pool tag or is within a specified size range. To request special pool for all allocations by a particular driver, use Driver Verifier. For more information, see the "Special Pool" topic in the "Driver Verifier" section of the Windows Driver Kit (WDK).

The special pool features of Gflags and Driver Verifier help you to detect and identify the source of errors in kernel pool use, such as writing beyond the allocated memory space, or referring to memory that has already been freed.

Not all special pool requests are fulfilled. Each allocation from the special pool uses one page of nonpageable physical memory and two pages of virtual address space. If the special pool is exhausted, memory is allocated from the standard pool until the special pool becomes available again. When a special pool request is filled from the standard pool, the requesting function returns a success status. It does not return an error, because the allocation has succeeded, even though it was not filled from special pool.

The size of the special pool increases with the amount of physical memory on the system; ideally this should be at least 1 Gigabyte (GB). On x86 machines, because virtual (in addition to physical) space is consumed, do not use the /3GB boot option when using special pool. It is also a good idea to increase the pagefile minimum/maximum quantities by a factor of two or three.

You can also configure the Special Pool feature to align memory allocation to detect references to memory preceding the allocation ("underruns") or references to memory beyond the allocation ("overruns"). This feature is available only in the Global Flags dialog box on all versions of Windows. For details, see [Detecting Overruns and Underruns](#).

On Windows Vista and later versions of Windows, you can configure the Special Pool feature as a registry setting that requires a reboot, but remains effective until you change it, or as a kernel flag setting that does not require a reboot, but is effective only until you reboot or shut down Windows. In earlier versions of Windows, Special Pool is only available as a registry setting.

On Windows Vista and later versions of Windows, you can configure the Special Pool feature either by using the Global Flags dialog box or at the command line. In earlier version of Windows, this feature is available only in the Global Flags dialog box.

## Stop on exception

The **Stop on exception** flag causes the kernel to break into the kernel debugger whenever a kernel-mode exception occurs.

**Abbreviation**        soe

**Hexadecimal value** 0x1

**Symbolic Name**     FLG\_STOP\_ON\_EXCEPTION

**Destination**        System-wide registry entry, kernel flag, image file registry entry

### Comments

Windows passes all first chance exceptions (except for STATUS\_PORT\_DISCONNECT) with a severity of Warning or Error to the debugger before passing them to a local exception handler.

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

## Stop on hung GUI

The **Stop on hung GUI** flag appears in GFlags, but it has no effect on Windows.

**Abbreviation**        shg

**Hexadecimal value** 0x8

**Symbolic Name**     FLG\_STOP\_ON\_HUNG\_GUI

**Destination**        Kernel flag

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

## Stop on unhandled user-mode exception

The **Stop on unhandled user-mode exception** flag causes a break into the kernel debugger whenever an unhandled user-mode exception occurs.

**Abbreviation** sue  
**Hexadecimal value** 0x20000000  
**Symbolic Name** FLG\_STOP\_ON\_UNHANDLED\_EXCEPTION  
**Destination** System-wide registry entry, kernel flag, image file registry entry

## GFlags Examples

The following examples show how to submit GFlags commands and how to use GFlags features in practical scenarios.

This section includes the following topics.

[Example 1: Displaying Global Flags](#)

[Example 2: Setting a Flag by Using a Flag Abbreviation](#)

[Example 3: Setting a Flag by Using Its Hexadecimal Value](#)

[Example 4: Setting Multiple Flags](#)

[Example 5: Clearing a Flag](#)

[Example 6: Clearing All Flags](#)

[Example 7: Clearing All Flags for an Image File](#)

[Example 8: Enlarging the User-Mode Stack Trace Database](#)

[Example 9: Detecting a Pool Memory Leak](#)

[Example 10: Detecting a Heap Memory Leak in a Process](#)

[Example 11: Enabling Page Heap Verification](#)

[Example 12: Using Page Heap Verification to Find a Bug](#)

[Example 13: Listing Image Files with Global Flags](#)

[Example 14: Configuring Special Pool](#)

[Example 15: Using Object Reference Tracing](#)

The examples in the second section apply to features available only in Windows Vista and later versions of Windows.

### Example 1: Displaying Global Flags

The commands demonstrated in this example display the system-wide flags set in the registry, the system flags set for the session (kernel mode), and the flags set for an image file.

The following GFlags command displays the current value of the system-wide flags set in the registry. It uses the /r parameter to specify the system-wide registry entry.

```
gflags /r
```

In response, GFlags displays a single hexadecimal value representing the sum of all flags set and a list of the flags set.

```
Current Boot Registry Settings are: 40001400
ptg - Enable pool tagging
ust - Create user mode stack trace database
bhd - Enable bad handles detection
```

In this example, the results show that there are three tags set, with a combined value of 0x40001400.

- [Enable pool tagging](#) (ptg) = 0x400
- [Create user mode stack trace database](#) (ust) = 0x1000
- [Enable bad handles detection](#) (bhd) = 0x40000000

The following command displays the flags set for the current session. It uses the /k parameter to indicate kernel mode.

```
gflags /k
```

The following command displays flags set in the registry for the image file notepad.exe. It uses the /i parameter to indicate image file mode and specifies the image file.

```
gflags /i notepad.exe
```

Remember that the flag value displayed might not be the current, effective flag value. Changes to the system-wide flags are not effective until you restart Windows. Changes to image file flag settings are not effective until you restart the program.

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

## Example 2: Setting a Flag by Using a Flag Abbreviation

The following command sets the [Show loader snaps](#) flag for the notepad.exe image file. **Show Loader Snaps** takes snapshots of the load process, capturing in detail the loading and unloading of executable images and their supporting library modules.

The command uses the /i parameter to indicate image file mode and specifies the name of the image file notepad.exe. To identify the flag, the command uses **s1s**, the abbreviation for **Show Loader Snaps**, and it precedes the abbreviation with a plus sign (+) to indicate that the flag is set. Without the plus sign, the command has no effect.

```
gflags /i notepad.exe +s1s
```

In response, GFlags displays the flags set for notepad.exe. The display indicates that the command is successful. The **Show Loader Snaps** feature is enabled for all new sessions of the Notepad program.

```
Current Registry Settings for notepad.exe executable are: 00000002
 s1s - Show Loader Snaps
```

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

## Example 3: Setting a Flag by Using Its Hexadecimal Value

The following command sets the system-wide [Enable page heap](#) flag. **Enable Page Heap** adds a guard page and other tracking features to each heap allocation.

The command uses the /r parameter to indicate system-wide registry mode. To identify the flag, the command uses **2000000**, which represents 0x2000000, the hexadecimal value for **Enable page heap**.

Although the command sets a flag, it omits the plus (+) sign. When using hexadecimal values, the sign is optional and add (+) is the default.

```
gflags /r 2000000
```

In response, GFlags displays the system-wide flags set in the registry. The display indicates that the command is successful. The **Enable page heap** feature will be enabled for all processes when Windows restarts.

```
Current Boot Registry Settings are: 02000000
 hpa - Enable page heap
```

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

## Example 4: Setting Multiple Flags

The following command sets these three flags for the current session:

- [Enable heap free checking](#) (hfc, 0x20)

- [Enable heap parameter checking](#) (hpc, 0x40)
- [Enable heap validation on call](#) (hvc, 0x80)

This command uses the /k parameter to specify kernel mode (session only). It sets the value for kernel mode to **E0** (0xE0), the sum of the hexadecimal values of the selected flags (0x20 + 0x40 + 0x80).

```
gflags /k e0
```

In response, GFlags displays the revised value of flags set for the session. The display indicates that the command is successful and that the three flags specified in the command are set.

```
Current Running Kernel Settings are: 000000e0
 hfc - Enable heap free checking
 hpc - Enable heap parameter checking
 hvc - Enable heap validation on call
```

You can use several different GFlags commands to set flags. Each of the following commands has the same effect as the command used in this example and the methods can be used interchangeably:

```
gflags /k +20 +40 +80
gflags /k +E0
gflags /k +hfc +hpc +hvc
```

Kernel (run time) flags are effective immediately and remain effective until Windows shuts down.

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

## Example 5: Clearing a Flag

The following command clears the system-wide [Enable page heap](#) flag set in the registry. The command uses the /r parameter to indicate the system-wide registry mode and **hpa**, the abbreviation for the [Enable page heap](#) flag. The minus sign (-) indicates that the flag is to be cleared.

```
gflags /r -hpa
```

In response, GFlags displays the current value of the system-wide registry entry. The display indicates that the command is successful and that there are no longer any flags set.

```
Current Boot Registry Settings are: 00000000
```

Note that the following command, which uses the hexadecimal value of the [Enable Page Heap](#) flag, has the same effect as the command used in this example. These commands can be used interchangeably:

```
gflags /r -02000000
```

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

## Example 6: Clearing All Flags

This example demonstrates two different ways to clear all flags set in the registry and for the session:

- Subtract the current flag value.
- Subtract high values.

**Note** The methods demonstrated by this example clear flags only. They do not reset the maximum stack trace size or kernel special pool tag to the default values.

### Subtract the Current Flag Value

The following command clears all flags set in the system-wide flag entry in the registry by subtracting the current value of the entry. In this example, the current value is 0xE0. The command uses the /r parameter to indicate the system-wide registry mode and the E0 value with a minus sign (-) to subtract E0 from the flag value.

```
gflags /r -E0
```

In response, GFlags displays the revised value of system-wide flag registry entry. A value of zero indicates that the command is successful and that there are no longer any system-wide flags set in the registry.

```
Current Boot Registry Settings are: 00000000
```

Note that the following commands have the same effect as the command used in this example and can be used interchangeably:

```
gflags /r -20 -40 -80
gflags /r -hfc -hpc -hvc
```

### Subtract High Values

The following command clears all system-wide flags by subtracting high values (0xFFFFFFFF) from the system-wide flag setting.

```
gflags /r -ffffffff
```

In response, GFlags displays the revised value of the system-wide flag entry. A value of zero indicates that the command is successful and that there are no longer any system-wide flags set in the registry.

```
Current Boot Registry Settings are: 00000000
```

**Tip** Type this command into Notepad, then save the file as clearflag.bat. Thereafter, to clear all flags, just type **ClearFlag**.

Finally, the following example demonstrates that the intuitive method of clearing all flags does not work.

The following command appears to set the value of the system-wide flag entry to 0. However, it actually adds zero to the system-wide flag value. In this example, the current value of the system-wide flag entry is 0xE0.

```
gflags /r 0
```

In response, GFlags displays the system-wide flag value after the command completes:

```
Current Boot Registry Settings are: 000000e0
 hfc - Enable heap free checking
 hpc - Enable heap parameter checking
 hvc - Enable heap validation on call
```

The command has no effect because it adds the value 0 to system-wide flag entry.

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

## Example 7: Clearing All Flags for an Image File

The following command clears all flags and image debugger options for an image file. The command adds high-values (0xFFFFFFFF) to the current flag value. GFlags responds by deleting the **GlobalFlag** registry entry for the image file, thereby deleting all of the values it stores.

This command does not affect flags set in the system-wide **GlobalFlag** registry entry or flags set for the session (kernel mode).

```
gflags /i notepad.exe ffffffff
```

In response, GFlags displays a message indicating that there are no flags set for the image file:

```
No Registry Settings for notepad.exe executable
```

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

## Example 8: Enlarging the User-Mode Stack Trace Database

The following GFlags command increases the maximum size of the user-mode stack trace database for myapp.exe, a fictitious program, from 8 MB to 24 MB.

The command uses the **/i** parameter to specify the image file. It uses the **/tracedb** parameter to set the maximum stack trace database size and the value 24 to indicate the size in megabytes. The command uses decimal units. (Hexadecimal units are not valid.)

```
gflags /i MyApp.exe /tracedb 24
```

As the following error message indicates, this command fails because the [Create user mode stack trace database](#) (+ust) flag is not set for the MyApp image file. You cannot set the size of a trace database until you create one.

```
Failed to set the trace database size for 'MyApp.exe'
```

The following commands fix the error. The first command creates a trace database for myapp.exe and the second command sets the maximum size of the trace database to 24 MB. These commands cannot be combined into a single command. The following display shows the commands and the success message from GFlags.

```
gflags /i MyApp.exe +ust
Current Registry Settings for MyApp.exe executable are: 00001000
 ust - Create user mode stack trace database

gflags /i MyApp.exe /tracedb 24
Trace database size for `MyApp.exe' set to 24 Mb.
```

GFlags can change the size of the user-mode stack trace database, but it does not display it. To display the trace database size, use registry APIs, Regedit, or Reg (reg.exe), a tool included in Windows XP and Windows Server 2003, to check the value of the **StackTraceDatabaseSizeInMB** registry entry (HKLM\Software\Microsoft\Windows NT\CurrentVersion\Image File Execution Options\ImagePathName\StackTraceDatabaseSizeInMB).

(A version of Reg is included in Windows XP, but that version does not permit the /v and /s switches in the same command.)

The following command uses Reg to query the value of **StackTraceDatabaseSizeInMB**:

```
reg query "HKLM\Software\Microsoft\Windows NT\CurrentVersion\Image File Execution Options\ImagePathName" /v StackTraceDatabaseSizeInMB
```

In response, Reg displays the value of **StackTraceDatabaseSizeInMB**, which confirms that the new value, 24 (0x18), was set. This value becomes effective when you restart myapp.exe.

```
! REG.EXE VERSION 3.0
HKEY_LOCAL_MACHINE\Software\Microsoft\Windows NT\CurrentVersion\Image File Execution Options\ImagePathName
 StackTraceDatabaseSizeInMB REG_DWORD 0x18
```

**Tip** Type the **reg query** command into Notepad, then save the file as tracedb.bat. Thereafter, to display the value of **StackTraceDatabaseSizeInMB**, just type **TraceDb**.

## Example 9: Detecting a Pool Memory Leak

The following example uses GFlags to set the system-wide [Enable pool tagging](#) flag in the registry. Then, it uses PoolMon (poolmon.exe), a tool in the Windows Driver Kit, to display the size of the memory pools.

PoolMon monitors the bytes in the paged and nonpaged memory pools and sorts them by pool tag. By running PoolMon periodically, you can identify pools that expand continuously over time. This pattern often indicates a memory leak.

**Note** Pool tagging is permanently enabled in Windows Server 2003 and later versions of Windows. On these systems, the **Enable pool tagging** check box on the **Global Flags** dialog box is dimmed, and commands to enable or disable pool tagging fail.

If pool tagging is not enabled, PoolMon fails and displays the following message: "Query pooltags Failed c0000002."

### ► To detect a pool memory leak

- To enable pool tagging for all processes in versions of Windows earlier than Windows Server 2003, set the system-wide [Enable pool tagging](#) flag in the registry. The following command line uses the flag abbreviation method, but you can identify the flag by its hexadecimal value or use the **Global Flags** dialog box:  

```
gflags /r +ptg
```
- Restart the computer to make the registry change effective.
- Run PoolMon periodically by using the following command. In this command, the **/b** parameter sorts the pools in descending size order.  

```
poolmon /b
```

In response, PoolMon displays allocations from the memory pools in descending size order, including the number of allocate operations and free operations, and the amount of memory remaining in the pool (in the Bytes column).

```
Memory: 16224K Avail: 4564K PageFlts: 31 InRam Krnl: 684K P: 680K
Commit: 24140K Limit: 24952K Peak: 24932K Pool N: 744K P: 2180K

 Tag Type Allocs Frees Diff Bytes Per Alloc
 --- --- -----
CM Paged 1283 (0) 1002 (0) 281 1377312 (0) 4901
Strg Paged 10385 (10) 6658 (4) 3727 317952 (512) 85
Fat Paged 6662 (8) 4971 (6) 1691 174560 (128) 103
MmSt Paged 614 (0) 441 (0) 173 83456 (0) 482
```

If the value in the **Bytes** column for an allocation expands continuously for no obvious reason, there might be a memory leak in that pool.

- Clear the **Enable pool tagging** flag.

The following command line uses the flag abbreviation method, but you can identify the flag by its hexadecimal value or use the **Global Flags** dialog box:

- ```
gflags /r -ptg
```
5. Restart Windows to make the registry change effective.

Note Use the append symbol (>>) to redirect the PoolMon output to a log file. Later, you can examine the log file for pool size trends. For example:

```
poolmon.exe /b >> poolmon.log
```

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

Example 10: Detecting a Heap Memory Leak in a Process

This example uses GFlags and User Mode Dump Heap (UMDH, umdh.exe), a tool included in Microsoft Debugging Tools for Windows.

► To detect a leak in heap memory in notepad.exe

1. Set the [Create user mode stack trace database \(ust\)](#) flag for the notepad.exe image file.

The following command uses GFlags to set the **Create user mode stack trace database** flag. It uses the /i parameter to identify the image file and the **ust** abbreviation for the flag.

```
gflags /i Notepad.exe +ust
```

As a result of this command, a user-mode stack trace is created for all new instances of the Notepad process.

2. Set the symbol file path.

The following command creates an environment variable that stores the path to the directory of symbol files:

```
set _NT_SYMBOL_PATH=C:\Windows\symbols
```

3. Start Notepad.

4. Find the process identifier (PID) of the Notepad process.

You can find the PID of any running process from Task Manager or Tasklist (tasklist.exe), a tool included in Windows XP Professional and Windows Server 2003 operating systems. In this example, the Notepad PID is 1228.

5. Run UMDH.

The following command runs UMDH (umdh.exe). It uses the **-p:** parameter to specify the PID that, in this example, is 1228. It uses the **/f:** parameter to specify the name and location of the output file for the heap dump, notepad.dmp.

```
umdh -p:1228 -f:notepad.dmp
```

In response, UMDH writes a complete dump of all active heaps to the notepad.dmp file.

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

Example 11: Enabling Page Heap Verification

The following commands enable full and standard page heap verification for myapp.exe, a fictitious program.

The first command enables *standard* page heap verification for myapp.exe. It uses the **/p** parameter to enable page heap for a process. By default, **/p** enables standard page heap.

```
gflags /p /enable myapp.exe
```

The following commands enable *full* page heap verification for the myapp.exe program. Although these commands create different settings in the registry, they are all functionally equivalent to selecting the **Enable page heap** check box for the myapp.exe image file in the **Global Flags** dialog box. These methods can be used interchangeably.

```
gflags /p /enable myapp.exe /full
gflags /i myapp.exe +hpa
gflags /i myapp.exe +02000000
```

The following commands disable full or standard page heap verification for the myapp.exe program, regardless of the command or dialog box method used to enable page

heap verification.

```
gflags /p /disable myapp.exe  
gflags /i myapp.exe -hpa  
gflags /i myapp.exe -02000000
```

Note When using the **/debug** or **/kdebug** parameters, use the **/p /disable** parameters to turn off the page heap verification (not the **/i -hpa** parameters). The **/p /disable** parameters disable page heap verification and delete registry entries that the debugger reads.

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

Example 12: Using Page Heap Verification to Find a Bug

The following series of commands demonstrates how to use the page heap verification features of GFlags and the NTSD debugger to detect an error in heap memory use. In this example, the programmer suspects that a fictitious application, pheap-buggy.exe, has a heap error, and proceeds through a series of tests to identify the error.

For details on NTSD, see [Debugging Using CDB and NTSD](#).

Step 1: Enable standard page heap verification

The following command enables standard page heap verification for pheap-buggy.exe:

```
gflags /p /enable pheap-buggy.exe
```

Step 2: Verify that page heap is enabled

The following command lists the image files for which page heap verification is enabled:

```
gflags /p
```

In response, GFlags displays the following list of programs. In this display, **traces** indicates standard page heap verification, and **full traces** indicates full page heap verification. In this case, pheap-buggy.exe is listed with **traces**, indicating that standard page heap verification is enabled, as intended.

```
pheap-buggy.exe: page heap enabled with flags (traces )
```

Step 3: Run the debugger

The following command runs the **CorruptAfterEnd** function of pheap-buggy.exe in NTSD with the **-g** (ignore initial breakpoint) and **-x** (set second-chance break on access violation exceptions) parameters:

```
ntsd -g -x pheap-buggy /CorruptAfterEnd
```

When the application fails, NTSD generates the following display, which indicates that it detected an error in pheap-buggy.exe:

```
=====  
VERIFIER STOP 00000008: pid 0xAA0: corrupted suffix pattern  
  
00C81000 : Heap handle  
00D81EB0 : Heap block  
00000100 : Block size  
00000000 :  
=====  
  
Break instruction exception - code 80000003 (first chance)  
eax=00000000 ebx=00d81eb0 ecx=77f7e257 edx=0006fa18 esi=00000008 edi=00c81000  
eip=77f7e098 esp=0006fc48 ebp=0006fc5c iopl=0 nv up ei pl zr na po nc  
cs=001b ss=0023 ds=0023 es=0023 fs=0038 gs=0000 efl=00000246  
ntdll!DbgBreakPoint:  
77f7e098 cc int 3
```

The header information includes the address of the heap with the corrupted block (00C81000 : Heap handle), the address of the corrupted block (00D81EB0 : Heap block), and the size of the allocation (00000100 : Block size).

The "corrupted suffix pattern" message indicates that the application violated the data integrity pattern that GFlags inserted after the end of the pheap-buggy.exe heap allocation.

Step 4: Display the call stack

In the next step, use the addresses that NTSD reported to locate the function that caused the error. The next two commands turn on line number dumping in the debugger and display the call stack with line numbers.

```
C:\>.lines  
Line number information will be loaded  
C:\>kb
```

```

ChildEBP RetAddr  Args to Child

0006ff24 010013a4 00c80000 01001002 00d81eb0 ntdll!RtlFreeHeap+0x69
0006ff3c 01001450 00000000 00000001 0006ffc0 pheap-buggy!TestCorruptAfterEnd+0x2b [d:\nttest\base\tests\kernel\rtl\pageheap\pheap-buggy.cxx @ 69]
0006ff4c 0100157f 00000002 00c65a68 00c631d8 pheap-buggy!main+0xa9 [d:\nttest\base\tests\kernel\rtl\pageheap\pheap-buggy.cxx @ 69]
0006ffc0 77de43fe 00000000 00000001 7ffd000 pheap-buggy!mainCRTStartup+0xe3 [crtexe.c @ 349]
0006fff0 00000000 0100149c 00000000 78746341 kernel32!DosPathToSessionPathA+0x204

```

As a result, the debugger displays the call stack for pheap-buggy.exe with line numbers. The call stack display shows that the error occurred when the **TestCorruptAfterEnd** function in pheap-buggy.exe tried to free an allocation at 0x00c80000 by calling **HeapFree**, a redirect to **RtlFreeHeap**.

The most likely cause of this error is that the program wrote past the end of the buffer that it allocated in this function.

Step 5: Enable full page heap verification

Unlike standard page heap verification, full page heap verification can catch the misuse of this heap buffer as soon as it occurs. The following command enables full page heap verification for pheap-buggy.exe:

```
gflags /p /enable pheap-buggy.exe /full
```

Step 6: Verify that full page heap is enabled

The following command lists the programs for which page heap verification is enabled:

```
gflags /p
```

In response, GFlags displays the following list of programs. In this display, **traces** indicates standard page heap verification, and **full traces** indicates full page heap verification. In this case, pheap-buggy.exe is listed with **full traces**, indicating that full page heap verification is enabled, as intended.

```
pheap-buggy.exe: page heap enabled with flags (full traces)
```

Step 7: Run the debugger again

The following command runs the **CorruptAfterEnd** function of pheap-buggy.exe in the NTSD debugger with the **-g** (ignore initial breakpoint) and **-x** (set second-chance break on access violation exceptions) parameters:

```
ntsd -g -x pheap-buggy /CorruptAfterEnd
```

When the application fails, NTSD generates the following display, which indicates that it detected an error in pheap-buggy.exe:

```

Page heap: process 0x5BC created heap @ 00880000 (00980000, flags 0x3)
ModLoad: 77db0000 77e8c000  kernel32.dll

Page heap: process 0x5BC created heap @ 00B60000 (00C60000, flags 0x3)
Page heap: process 0x5BC created heap @ 00C80000 (00D80000, flags 0x3)
Access violation - code c0000005 (first chance)
Access violation - code c0000005 (!!! second chance !!!)
eax=00c86f00 ebx=00000000 ecx=77fdb80f edx=00c85000 esi=00c80000 edi=00c16fd0
eip=01001398 esp=0006ff2c ebp=0006ff4c iopl=0 nv up ei pl nz na po nc
cs=001b ss=0023 ds=0023 es=0023 fs=0038 gs=0000 efl=00000206
pheap-buggy!TestCorruptAfterEnd+1f:
01001398 889801010000    mov     [eax+0x101],bl        ds:0023:00c87001=???

```

With full page heap verification enabled, the debugger breaks at an access violation. To find the precise location of the access violation, turn on line number dumping and display the call stack trace.

The numbered call stack trace appears as follows: The line displaying the problem appears in bold text.

```

ChildEBP RetAddr  Args to Child
0006ff3c 01001450 00000000 00000001 0006ffc0 pheap-buggy!TestCorruptAfterEnd+0x1f [d:\nttest\base\tests\kernel\rtl\pageheap\pheap-buggy.cxx @ 69]
0006ff4c 0100157f 00000002 00c16fd0 00b70eb0 pheap-buggy!main+0xa9 [d:\nttest\base\tests\kernel\rtl\pageheap\pheap-buggy.cxx @ 69]
0006ffc0 77de43fe 00000000 00000001 7ffd000 pheap-buggy!mainCRTStartup+0xe3 [crtexe.c @ 349]
WARNING: Stack unwind information not available. Following frames may be wrong.
0006fff0 00000000 0100149c 00000000 78746341 kernel32!DosPathToSessionPathA+0x204

```

The stack trace shows that the problem occurs in line 184 of pheap-buggy.exe. Because full page heap verification is enabled, the call stack starts in the program code, not in a system DLL. As a result, the violation was caught where it happened, instead of when the heap block was freed.

Step 8: Locate the error in the code

A quick inspection reveals the cause of the problem: The program tries to write to the 257th byte (0x101) of a 256-byte (0x100) buffer, a common off-by-one error.

```
* ((PCHAR)Block + 0x100) = 0;
```

Example 13: Listing Image Files with Global Flags

GFlags displays the flags set for a particular image file, but it does not display all image files that have flags set.

Windows stores flags for an image file that the **GlobalFlag** registry entry in a registry subkey named for the image file in the following registry path, **HKEY_LOCAL_MACHINE\ SOFTWARE\ Microsoft\ Windows NT\ CurrentVersion\ Image File Execution Options\ ImageFileName\ GlobalFlag**.

To determine which image files have flags set, use Reg (reg.exe), a tool included in Windows Server 2003.

The following Reg **Query** command searches for the **GlobalFlag** registry entry in the specified registry path. The **-v** parameter specifies the **GlobalFlag** registry entry. The **/s** parameter makes the search recursive.

```
reg query "HKLM\Software\Microsoft\Windows NT\CurrentVersion\Image File Execution Options" /v GlobalFlag /s
```

In response, Reg displays all instances of the **GlobalFlag** registry entry in the path and the value of the entry.

```
HKEY_LOCAL_MACHINE\Software\Microsoft\Windows NT\CurrentVersion\Image File Execution Options\notepad.exe
    GlobalFlag      REG_SZ      0x00001000

HKEY_LOCAL_MACHINE\Software\Microsoft\Windows NT\CurrentVersion\Image File Execution Options\photohse.EXE
    GlobalFlag      REG_SZ      0x00200000

HKEY_LOCAL_MACHINE\Software\Microsoft\Windows NT\CurrentVersion\Image File Execution Options\printhse.EXE
    GlobalFlag      REG_SZ      0x00200000
```

Tip Type the **Reg** command into Notepad, then save the file as **imageflags.bat**. Thereafter, to find image files for which flags have been set, just type **ImageFlags**.

Example 14: Configuring Special Pool

Beginning in Windows Vista, you can configure the [Special Pool](#) feature as a kernel flag setting or as a registry setting. If you configure it as a kernel flag (run time) setting, you do not need to restart the computer to make the change effective. In earlier versions of Windows, Special Pool is available only as a registry setting.

Also, beginning in Windows Vista, you can set and configure the Special Pool feature from the command line. In earlier versions of Windows, you can set and configure the Special Pool feature only in the Global Flags dialog box.

Request Special Pool by pool tag without rebooting

The following command requests special pool for all allocations with the **Tag1** pool tag. This setting becomes effective immediately, but it is lost if you shut down or restart Windows.

This command uses the **/k** parameter to specify a kernel flag (run time) setting and the **+spp** abbreviation to set a special pool request.

```
gflags /k +spp Tag1
```

GFlags responds by printing:

```
Special Pool set to 0x31676154
PoolTagOverruns set to 0x1
Current Running Kernel Settings are: 00000000
```

Notice that the special pool allocation request is not a kernel flag setting and is not reflected in the kernel settings value.

Also, a special pool allocation request does not change the value of the overrun (0x1) or underrun (0x0) setting for special pool. To change from overruns, the default, to underruns, use the GFlags Dialog Box. For information, see [Detecting Overruns and Underruns](#).

You cannot display the pool tag at the command line. To verify that the pool tag is a kernel setting, use the GFlags Dialog Box.

Request Special Pool by pool tag in the registry

The following command requests special pool for all allocations with the **Tag1** pool tag. Because this setting is stored in the registry, you must restart the computer to make it effective, but it remains effective until you change it.

This command uses the **/r** parameter to specify a registry setting and the **+spp** abbreviation to set a special pool request.

```
gflags /r +spp Tag1
```

GFlags responds by printing:

```
Special Pool set to 0x31676154
PoolTagOverruns set to 0x1
Current Boot Registry Settings are: 00000000
```

Notice that the special pool allocation request is not a registry flag setting and is not reflected in the registry settings value.

Also, a special pool allocation request does not change the value of the overrun (0x1) or underrun (0x0) setting for special pool. To change from overruns, the default, to underruns, use the Gflags Dialog Box. For information, see [Detecting Overruns and Underruns](#).

To verify that the value has been added to the registry, use Reg or Regedit to display the value of the **PoolTag** entry in the **HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Control\Session Manager\Memory Management** key.

For example:

```
c:>reg query "HKLM\SYSTEM\CurrentControlSet\Control\Session Manager\Memory Management" -v PoolTag
HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Control\Session Manager\Memory Management
  PoolTag      REG_DWORD      0x31676154
```

Request Special Pool by size without rebooting

The following command requests special pool for allocations of 1 to 8 bytes on an x86 computer with a PAGE_SIZE of 0x1000 and allocation granularity of 8 bytes.

This command uses the /k parameter to specify a kernel flag (run time) setting and the +spp abbreviation to set a special pool request. The size value is preceded by 0x to indicate that it is a size and not a pool tag.

The value, 0x10, is calculated by adding the allocation granularity (8 bytes) to the largest size in the range (8 bytes) for a total of 16 bytes (0x10). For help in determining the correct value to enter, see "Selecting an Allocation Size" in [Special Pool](#).

```
gflags /k +spp 0x10
```

Gflags responds by printing:

```
Special Pool set to 0x10
PoolTagOverruns set to 0x1
Current Running Kernel Settings are: 00000000
```

Again, the special pool allocation request is not a kernel flag setting and is not reflected in the kernel settings value.

Also, a special pool allocation request does not change the value of the overrun (0x1) or underrun (0x0) setting for special pool. To change from overruns, the default, to underruns, use the Gflags Dialog Box. For information, see [Detecting Overruns and Underruns](#).

Request Special Pool by size in the registry

The following command requests special pool for allocations of 1024 to 1040 bytes on an x64 computer with a PAGE_SIZE of 0x1000 and allocation granularity of 16 bytes.

This command uses the /r parameter to specify a system-wide registry setting and the +spp abbreviation to set a special pool request. The size value is preceded by 0x to indicate that it is a size and not a pool tag.

The value, 0x420, is calculated by adding the allocation granularity (16 bytes) to the largest size in the range (1040 bytes) for a total of 1056 bytes (0x420). For help in determining the correct value to enter, see "Selecting an Allocation Size" in [Special Pool](#).

```
gflags /r +spp 0x420
```

Gflags responds by printing:

```
Special Pool set to 0x420
PoolTagOverruns set to 0x1
Current Boot Registry Settings are: 00000000
```

Again, the special pool allocation request is not a registry flag setting and is not reflected in the registry settings value.

Also, a special pool allocation request does not change the value of the overrun (0x1) or underrun (0x0) setting for special pool. To change from overruns, the default, to underruns, use the Gflags Dialog Box. For information, see [Detecting Overruns and Underruns](#).

To verify that the value has been added to the registry, use Reg or Regedit to display the value of the **PoolTag** entry in the **HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Control\Session Manager\Memory Management** key.

For example:

```
c:>reg query "HKLM\SYSTEM\CurrentControlSet\Control\Session Manager\Memory Management" -v PoolTag
HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Control\Session Manager\Memory Management
  PoolTag      REG_DWORD      0x420
```

Cancel a Special Pool Request

The following command cancels a request for Special Pool as a kernel flag (run time) setting. The command is the same for a request by pool tag or by size.

```
gflags /k -spp
```

The following command cancels a request for Special Pool as a registry setting. The command is the same for a request by pool tag or by size.

```
gflags /r -spp
```

When the command is successful, Gflags responds by printing:

Special Pool value has been deleted.

Example 15: Using Object Reference Tracing

Object Reference Tracing is a Windows feature that records a sequential stack trace when an object is referenced or dereferenced. It is designed to detect errors in object handling that can lead to crashes or memory leaks. Some of these errors are difficult to detect because they do not appear consistently. For detailed information, see [Object Reference Tracing](#).

You can configure Object Reference Tracing by using the **Global Flags** dialog box or at a command prompt. The following examples use the command prompt. For information about using the **Global Flags** dialog box to configure Object Reference Tracing, see [Configuring Object Reference Tracing](#).

You can use Gflags to enable, disable, and configure Object Reference Tracing. The process is as follows:

- **Use Gflags to enable Object Reference Tracing** in the registry or as a kernel flag (run time) setting. If you add the setting to the registry, you must restart the computer to start tracing. If you enable the run time version of the settings, the trace starts immediately, but the trace settings revert to those in the registry key when you shut down or restart the computer.
- **Start the process that creates the suspect object.** The trace includes only objects created by processes that are started after the trace begins. If the process starts during or soon after restarting, add the trace settings to the registry, and then restart the system.
- **Use the `!obtrace` debugger extension** to view the trace. By default, the trace is maintained until the object is destroyed, but you can use the `/p` parameter to maintain the trace until tracing is disabled.
- **Use Gflags to disable Object Reference Tracing.** in the registry or as a kernel flag (run time) setting. If you delete the setting from the registry, you must restart the computer to end tracing. If you disable the run time version of the settings, the trace ends immediately, but the trace settings revert to those in the registry when you shut down or restart the computer.

These examples show how to use Gflags to enable and disable object reference tracing.\

Enable Run-time Tracing

The following command enables Object Reference Tracing at the command prompt. The command uses the `/ko` parameter to enable Object Reference Tracing as a kernel flag (run time) setting. The command uses the `/t` parameter to specify the pool tags **Tag1** and **Fred**. As a result, all objects that are created with **Tag1** or **Fred** are traced.

```
gflags /ko /t Tag1;Fred
```

Because the command changes the kernel flag (run-time) settings, object reference tracing starts immediately. The trace will include all objects with the pool tags **Tag1** or **Fred** that are created by processes that start after the command is submitted.

Gflags responds by printing the following message:

```
Running Kernel Settings :  
Object Ref Tracing Enabled  
Temporary Traces  
Pool Tags: Tag1;Fred  
Process Name: All Processes
```

This message indicates that Object Reference Tracing is enabled. "Temporary Traces" indicates that all records of the trace are deleted when the object is destroyed. To make the trace "permanent," use the `/p` parameter, which directs Windows to retain the trace data until Object Reference Tracing is disabled, or the computer is shut down or restarted.

Enable Tracing in the Registry

The following command adds an Object Reference Tracing configuration to the registry. The trace that you configure begins when you restart the computer.

The command uses the `/ro` parameter to enable Object Reference Tracing as a registry setting. The command uses the `/i` to specify the process for notepad.exe and the `/t` parameter to specify the pool tags **Tag1** and **Fred**. As a result, all objects that are created by the Notepad process with the **Tag1** or **Fred** pool tags are traced. The command also uses the `/p` parameter, which retains the trace data until the tracing is disabled.

```
gflags /ro /t Tag1;Fred /i Notepad.exe /p
```

When you submit the command, Gflags stores the information in the registry. However, because registry settings are not effective until you restart the computer, this object reference tracing is configured, but is not yet started.

Gflags responds by printing the following message:

```
Boot Registry Settings :  
Object Ref Tracing Enabled  
Permanent Traces  
Pool Tags: Tag1;Fred  
Process Name: Notepad.exe
```

The message indicates that Object Reference Tracing is enabled in the registry. "Permanent Traces" indicates that the trace data will be retained until you shut down or restart the computer. The message also lists the pool tags and image file names that will be traced.

Display the Object Reference Tracing Configuration

You can display the Object Reference Tracing configuration that is currently effective or is stored in the registry to be used when the computer is restarted.

In this example, there is one Object Reference Tracing configuration stored in the registry and a different one configured for run time. The run-time trace begins immediately (and overrides any registry settings). However, if you restart the system, the run-time settings are lost, and the Object Reference Tracing session registry settings become effective.

The following command displays the run time Object Reference Tracing configuration. It uses the **/ko** parameter with no other parameters.

```
gflags /ko  
Running Kernel Settings :  
Object Ref Tracing Enabled  
    Temporary Traces  
    Pool Tags: Tag1;Fred  
    Process Name: All Processes
```

If Object Reference Tracing is enabled, as it is in this example, the settings that are displayed describe a trace that is in progress.

The following command displays the Object Reference Tracing configuration data stored in the registry. It uses the **/ro** parameter with no other parameters.

```
gflags /ro
```

In response, Gflags displays the data stored in the registry:

```
Boot Registry Settings :  
Object Ref Tracing Enabled  
    Permanent Traces  
    Pool Tags: Tag1;Fred  
    Process Name: Notepad.exe
```

If you have restarted the computer since you added the Object Reference Tracing configuration to the registry, the settings that are displayed in response to a gflags /ro command describe the trace that is in progress. However, if you have not yet restarted, or you have restarted, but then started a run-time object reference trace (**/ko**), the settings that are stored in the registry are not currently effective, but they will become effective again when you reboot the system.

Disable Object Reference Tracing

When you disable run-time (kernel flag) Object Reference Tracing settings, the trace stops immediately. When you disable Object Reference Tracing settings in the registry, the trace stops when you restart the computer.

The following command disables run-time Object Reference Tracing. It uses the **/d** parameter to disable all settings. You cannot disable settings selectively.

```
gflags /ko -d
```

When the command succeeds, Gflags responds with the following message:

```
Running Kernel Settings :  
Object Ref Tracing Disabled
```

The following command disables run-time Object Reference Tracing.

The following command disables Object Reference Tracing settings in the registry. It uses the **/d** parameter to disable all settings. You cannot disable settings selectively. This command is effective when you restart the computer.

```
gflags /ro -d
```

When the command succeeds, Gflags responds with the following message:

```
Boot Registry Settings :  
Object Ref Tracing Disabled
```

Kill Tool

The Kill tool, kill.exe, terminates one or more processes and all of their threads. This tool works only on processes running on the local computer.

Where to get Kill Tool

Kill.exe is included in [Debugging Tools for Windows](#).

Kill Tool command-line options

```
kill [/f] { PID | Pattern* }
```

Parameters

/f

Forces the termination of the process without prompting the user for confirmation. This option is required to terminate a protected process, such as a system service.

PID

Specifies the process identifier (PID) of the task to be terminated.

To find the PID for a task, use TaskList in Microsoft Windows XP and later or [TList](#) in Windows 2000.

Pattern*

Specifies all or part of the name of a task or window. The Kill tool terminates all processes whose process names or window names match the pattern. The asterisk is required.

Before using a pattern that might match many process or window names unintentionally, use the `tlist pattern` command to test the pattern. See [TList](#) for details.

Examples

The following command terminates processes whose names begin with "myapp."

```
kill myapp*
```

The following command terminates the process whose process ID (PID) is 2520:

```
kill 2520
```

The following command terminates processes whose names begin with "my*." It does not prompt for confirmation. This command succeeds even when this process is a system service:

```
kill /f my*
```

Logger and LogViewer

The *Logger* and *LogViewer* tools provide an alternative to standard user-mode debugging. Logger can monitor the actions of a user-mode target application and record all of its API calls. The resulting information can be displayed in the debugger, saved as a text file, or displayed in a powerful interactive format by the LogViewer tool..

Where to get Logger and LogViewer

Logger and LogViewer are included in [Debugging Tools for Windows](#).

In this section

[Logger](#)

[LogViewer](#)

[The Logger Manifest](#)

Related topics

[Tools Included in Debugging Tools for Windows](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

Logger

The Logger tool can be activated through two different vehicles. One way is to use the stand-alone Logger.exe program. The other is to start CDB or WinDbg, and use the

Logexts.dll debugger extensions. Both of these methods will produce the same type of log output. However, the best vehicle to use on any NT-based operating system is CDB or WinDbg with the Logexts.dll extension commands.

The Logger vehicle works as well, but using the debugger gives you the full power of the debugger along with the power of Logger.

This section includes:

[Using the Debugger and Logexts.dll](#)

[Using Logger.exe](#)

[Logger Restrictions and Limitations](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

Using the Debugger and Logexts.dll

One way to activate Logger is to start CDB or WinDbg and attach to a user-mode target application as usual. Then, use the [!logexts.logi](#) or [!logexts.logc](#) extension command.

This will insert code at the current breakpoint that will jump off to a routine that loads and initializes Logexts.dll in the target application process. This is referred to as "injecting Logger into the target application."

There will actually be two instances of Logexts.dll running, since this module is both a debugger extension DLL and the program that is injected into the target application. The debugger and target instances of Logexts.dll communicate through a shared section of memory that includes the output file handles, current category mask, and a pointer to the log output buffer.

Attaching to the Target Application

For information about attaching the debugger to the target application, see [Debugging a User-Mode Process Using WinDbg](#) or [Debugging a User-Mode Process Using CDB](#).

Using the Logger Extension Commands

For the full syntax of each extension, see its reference page.

[!logexts.logi](#)

Injects Logger into the target application. This initializes logging, but does not enable it.

[!logexts.logc](#)

Enables logging. If [!logexts.logi](#) has not been used, this extension will initialize and then enable logging.

[!logexts.logd](#)

Disables logging. This will cause all API hooks to be removed in an effort to allow the program to run freely. COM hooks are not removed because they cannot be re-enabled at will.

[!logexts.loge](#)

Displays or modifies output options. Three types of output are possible: messages sent directly to the debugger, a text file, or an .lgv file. The .lgv file contains much more information than the other two; it can be read with [LogViewer](#).

If you disable the text file output, a .txt file of size zero will still be created. This may overwrite a previously-saved text file in the same location.

[!logexts.logm](#)

Displays available API categories, controls which categories will be logged and which will not, and displays the APIs that are contained in any category.

If a category is disabled, the hooks for all APIs in that category will be removed so that there is no longer any performance overhead. COM hooks are not removed because they cannot be re-enabled at will.

Enabling only certain categories can be useful when you are only interested in a particular type of interaction that the program is having with Windows -- for example, file operations. This reduces the log file size and also reduces the effect that Logger has on the execution speed of the process.

[!logexts.logf](#)

Displays or flushes the current output buffer. As a performance consideration, log output is flushed to disk only when the output buffer is full. By default, the buffer is 2144 bytes.

Since the buffer memory is managed by the target application, the automatic writing of the buffer to the log files on the disk will not occur if there is an access violation or some other non-recoverable error in the target application. In such cases, you should use this command to manually flush the buffer to the disk, or else the most recently-logged APIs may not appear in the log files.

[!logexts.logm](#)

Displays or creates a module inclusion/exclusion list. It is often desirable to only log those API calls that are made from a certain module or set of modules. To facilitate

that, Logger allows you to specify a module inclusion list or, alternatively, a module exclusion list. For instance, you would use an inclusion list if you only wanted to log calls from one or two modules. If you wanted to log calls made from all modules except a short list of modules, you would use an exclusion list. The modules Logexts.dll and Kernel32.dll are always excluded, since Logger is not permitted to log itself.

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

Using Logger.exe

One way to activate Logger is to run the stand-alone Logger.exe program. This is essentially a very small debugger that can only take a single target. To run it, include the name of the target application on the command line:

```
logger Target
```

When this is activated, it will load the specified application, and insert code into the target application that will jump off to a routine that loads and initializes Logexts.dll in the target application process. This is referred to as "injecting Logger into the target application."

The Logger.exe utility and the Logexts.dll module are the two components of this Logger vehicle. They communicate through a shared section of memory that includes the output file handles, current category mask, and a pointer to the log output buffer.

A window entitled **Logger (debugger)** will appear. This window will display the progress of Logger.

Change Settings Dialog Box

After the initialization finishes and the initial display is complete, the **Change Settings** dialog box will appear. This allows you to configure the Logger settings. The various settings are described here:

API Settings

This list displays the available API categories. The highlighted categories will be logged; the non-highlighted categories will not. The first time you run Logger, all categories will be highlighted. However, on subsequent runs, Logger will keep track of which categories are selected for a given target application.

If a category is disabled, the hooks for all APIs in that category will be removed so that there is no longer any performance overhead. COM hooks are not removed because they cannot be re-enabled at will.

Enabling only certain categories can be useful when you are only interested in a particular type of interaction that the program is having with Windows -- for example, file operations. This reduces the log file size and also reduces the effect that Logger has on the execution speed of the process.

Logging

This section contains **Enable** and **Disable** radio buttons. Disabling logging will cause all API hooks to be removed in an effort to allow the program to run freely. COM hooks are not removed because they cannot be re-enabled at will.

Inclusion / Exclusion List

This section controls the module inclusion/exclusion list. It is often desirable to log only those function calls that are made from a certain module or set of modules. To facilitate that, Logger allows you to specify a module inclusion list or, alternatively, a module exclusion list. For instance, you would use an inclusion list if you only wanted to log calls from one or two module. If you wanted to log calls made from all modules except a short list of modules, you would use an exclusion list. The modules Logexts.dll and Kernel32.dll are always excluded, since Logger is not permitted to log itself.

Flush the Buffer

This button will flush the current output buffer. As a performance consideration, log output is flushed to disk only when the output buffer is full. By default, the buffer is 2144 bytes.

Since the buffer memory is managed by the target application, the automatic writing of the buffer to the log files on the disk will not occur if there is an access violation or some other non-recoverable error in the target application. In such cases, you should try to activate the target application's window and hit F12 to get this dialog box back, and then press **Flush the Buffer**. If this is not done, the most recently-logged functions might not appear in the log files.

Go

This causes the target application to begin executing.

Running the Target Application

Once you have chosen the settings, click **Go**. The dialog box will close and the target application will begin to run.

If you make the target application's window active and press F12, it will break into Logger. This will cause the target application to freeze and the **Change Settings** dialog box to reappear. You can alter the settings if you wish, and then press **Go** to continue execution.

You can let the target application run for as long as you wish. If it terminates normally or due to an error, the logging will stop and cannot be restarted.

When you wish to exit, select **File | Exit** and click **Yes**. If the target application is still running, it will be terminated.

Limitations of Logger.exe

When you are running Logger through the Logger.exe tool, it will create only one output file -- an .lgv file. No text file will be written. However, a .txt file of size zero will be

created; this could overwrite a text log written by the debugger previously.

The output file will always be placed in LogExts subdirectory of the desktop; this location cannot be changed.

These limitations will not apply if you are running Logger through the debugger and Logexts.dll.

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

Logger Restrictions and Limitations

Logger increases stack consumption for a process because it introduces an additional "wrapping" function before the actual function call.

This can expose bugs in applications that are usually related to uninitialized variables. Since Logger alters stack usage, a local variable declared in a function call might take a different initial value than it does without the presence of Logger. If the program uses this variable without initializing it, the program might crash or otherwise behave differently than if Logger was not present.

Unfortunately, there is no easy way around such problems. The only workaround is to try disabling categories of functions in an attempt to isolate the area that is causing the problem.

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

LogViewer

The LogViewer utility can manipulate an .lgv file, which is a compressed log file produced by the Logger tool. To load a file, simply launch Logviewer.exe through Windows Explorer or from a Command Prompt window. It will take a moment to parse the manifest files. Once this is complete, you can invoke **File | Open** and select the desired .lgv file.

Once LogViewer has opened an .lgv file, it will display a list of all functions in the order they were logged. LogViewer supports powerful commands to filter out functions that you are not interested in. It can also save a filtered version of the log file as a text file.

This section includes:

[Reading the LogViewer Display](#)

[Filtering the LogViewer Function List](#)

[Exporting LogViewer Files to Text](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

Reading the LogViewer Display

LogViewer displays a list of all functions in the order they were logged.

Each row of the display contains several columns. The significance of each column is as follows.

Column	Meaning
+/	If this column contains a "+" (plus sign), it indicates that the function takes one or more parameters. To see the parameters and their values, either double-click the row or hit the right arrow key when the row is outlined in red. To hide it again, double click it again or hit the left arrow key when the row is outlined in red.
#	The sequential row number of the function call. This is useful when you have filters applied and are interested to know how far apart two function calls are.
Thrd	The thread number on which the function call was made. This number is not a thread ID, but is rather an assigned number based on the order that threads were created in the process.
Caller	The instruction address that made the function call. This is derived from the return address for the call. It is actually the return address minus 5 bytes (the typical size of a call dword ptr instruction).
Module	The module that contains the calling instruction.
API Function	The name of the function. The name of the module that contains the function is omitted for brevity.
Return	

Value The value returned by the function, if it is not a void function.

Double-clicking on a row in the viewer will expand the row to reveal the parameters to the function and their values "going in" to the function. If they are designated as OUT parameters, their value "coming out" is shown on the right.

You can also use the ENTER key or the right and left arrow keys to expand and collapse rows.

Function calls that returned failure status codes are shaded in pink.

Filtering the LogViewer Function List

Logger usually captures some function calls that are not needed for your analysis. These can be filtered out by Logger when it creates the log file. However, this process is not reversible, so it is usually preferable to allow all functions to be logged, and then filter the display in LogViewer.

There are several ways to filter out function calls in LogViewer:

- In the main viewing area, selected a function by clicking on it or using the cursor keys. (When a function is selected, LogViewer outlines it in red.) Then, press the DELETE key, or right-click and select **Hide**. This will hide all instances of that function call from view.
- Select **View | APIs Display**. A dialog box will appear that has three areas. On the right is an alphabetical listing of all functions, and on the left are categorical groupings. You can enable or disable the display of any function by checking or clearing the box to the left of its name.
- Select **View | Modules Display**. A dialog box will appear that allows you to select calling modules; only those functions that were called from these modules will be displayed.
- Select **View | First Level Calls Only**. This will display only calls that have "d0" in the left column. It is often desirable to hide function calls that are made by other logged functions. (For example, it is usually not interesting to know that **ShellExecuteEx** makes thirty different registry calls during its course of execution.)

Exporting LogViewer Files to Text

A powerful way to manipulate log files is to export them to text. This allows you to find specific parameter values by using the Find facility of any text editor. Although it is possible for a text file to be generated by Logger directly, you will have more flexibility if you use LogViewer to filter the function calls or add aliasing, and then export this information into a text file.

To create a text file from an .lvg file, open the file in LogViewer, and then select **File | Export to Text**. In the dialog box, choose a file name and location.

There are several options at the bottom of the dialog box:

Export Diff Information

This option will alias all pointers, handle values, and other values that change from execution to execution. Instead of outputting the actual value of a pointer (for example, "0x00123FA2"), LogViewer will output "Pointer." Similarly, handles will be aliased as "HeapHandle1" or some other value that will not register as a *diff* when the two files are compared using a differencing tool.

Include Non-Visible Rows

This option disables whatever filters are currently applied to the view while exporting.

Create a Separate File For Each Thread

This option splits up the text file by thread, making it easier to follow a thread of execution. This is useful if you intend to "diff" two instances of execution.

Export Range

This option specifies the range of rows to export.

The Logger Manifest

This section includes:

[Overview of the Logging Manifest](#)

[Manifest File Placement](#)

[Manifest File Format](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

Overview of the Logging Manifest

The logging manifest is the group of "header" files that define the functions and COM interfaces that are intercepted and logged. These are not true C++ header files -- they are in a slightly different format that explicitly declares the information needed by Logger.

For example, the manifest format facilitates the following features:

- Designation of OUT parameters. These are parameters that should be logged both on their way into a function and also on their way out.
- Definition of flag masks. This feature allows LogViewer to break a DWORD flag into its constituent bit labels for easier reading.
- Definition of failure cases. This feature allows LogViewer to shade the rows of functions that have returned a failure status code or another error code. Also, if the function sets the "LastError" value for the thread, LogViewer can store away the error code and expand it to its corresponding human-readable error message.
- Designation of parameters that can be aliased for log differencing. This feature gives LogViewer the option of assigning a constant string to a value that changes from execution to execution like pointers and handles when it exports the data to a file. You can then use a differencing tool to compare two execution logs for discrepancies. If pointers and handle values were not aliased, they would produce uninteresting discrepancies when the two files are compared.

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

Manifest File Placement

The primary manifest file must be named Main.h.

When Logger is running, Main.h must be located in the Manifest subdirectory of the directory containing Logexts.dll.

LogViewer is more flexible than Logger. It will search for Main.h in the following directories in this order:

1. The Manifest directory subordinate to the directory containing Logviewer.exe
2. The WinExt\Manifest directory subordinate to the directory containing logviewer.exe
3. The %WinDir%\System32\Manifest directory
4. The %WinDir%\System\Manifest directory

All additional manifest files must reside in the same directory as Main.h.

Manifest File Format

The file format for the manifest files borrows as much from C++ and IDL as possible. As a result, it is fairly easy to take a normal C++ SDK header file and modify it to be a manifest file. The parser fully supports C and C++ style comments to help you organize and document the file.

If you are attempting to add a manifest file or make alterations to an existing file, the best way to do it is to just experiment. When you issue a !logexts.logi or !logexts.loge command in the debugger, Logger will attempt to parse the manifest files. If it encounters a problem, it will produce an error message which might indicate the mistake.

A manifest file is made up of the following basic elements: module labels, category labels, function declarations, COM interface definitions, and type definitions. Other types

of elements exist as well, but these are the most important.

Module Labels

A module label simply declares what DLL exports the functions that are declared thereafter. For example, if your manifest file is for logging a group of functions from Comctl32.dll, you would include the following module label before declaring any function prototypes:

```
module COMCTL32.DLL:
```

A module label must appear before any function declarations in a manifest file. A manifest file can contain any number of module labels.

Category Labels

Similar to a module label, a category label identifies which "category" all subsequent functions and/or COM interfaces belong to. For example, if you are creating a Comctl32.dll manifest file, you can use the following as your category label:

```
category CommonControls:
```

A manifest file can contain any number of category labels.

Function Declarations

A function declaration is what actually prompts Logger to log something. It is nearly identical to a function prototype found in a C/C++ header file. There are a few notable additions to the format, which can be best illustrated by the following example:

```
HANDLE [gle] FindFirstFileA(
    LPCSTR lpFileName,
    [out] LPWIN32_FIND_DATAA lpFindFileData);
```

The function **FindFirstFileA** takes two parameters. The first is *lpFileName*, which is a full path (usually with wildcards) defining where to search for a file or files. The second is a pointer to a WIN32_FIND_DATAA structure that will be used to contain the search results. The returned HANDLE is used for future calls to **FindNextFileA**. If **FindFirstFileA** returns INVALID_HANDLE_VALUE, then the function call failed and an error code can be procured by calling the **GetLastError** function.

The HANDLE type is declared as follows:

```
value DWORD HANDLE
{
#define NULL 0 [fail]
#define INVALID_HANDLE_VALUE -1 [fail]
};
```

If the value returned by this function is 0 or -1 (0xFFFFFFFF), Logger will assume that the function failed, because such values have a [fail] modifier in the value declaration. (See the Value Types section later in this section.) Since there is a [gle] modifier right before the function name, Logger recognizes that this function uses **GetLastError** to return error codes, so it captures the error code and logs it to the log file.

The [out] modifier on the *lpFindFileData* parameter informs Logger that the data structure is filled in by the function and should be logged when the function returns.

COM Interface Definitions

A COM interface is basically a vector of functions that can be called by a COM object's client. The manifest format borrows heavily from the Interface Definition Language (IDL) used in COM to define interfaces.

Consider the following example:

```
interface IDispatch : IUnknown
{
    HRESULT GetTypeInfoCount( UINT pctinfo );

    HRESULT GetTypeInfo(
        UINT iTInfo,
        LCID lcid,
        LPOLECHAR* rgszNames,
        UINT cNames,
        LCID lcid,
        [out] DISPID* rgDispId );

    HRESULT GetIDsOfNames(
        REFIID riid,
        LPOLECHAR* rgszNames,
        UINT cNames,
        LCID lcid,
        [out] DISPID* rgDispId );

    HRESULT Invoke(
        DISPID dispIdMember,
        REFIID riid,
        LCID lcid,
        WORD wFlags,
        DISPPARAMS* pDispParams,
        VARIANT* pVarResult,
        EXCEPINFO* pExcepInfo,
        UINT* puArgErr );
};
```

This declares an interface called **IDispatch** that is derived from **IUnknown**. It contains four member functions, which are declared in specific order within the interface's braces. Logger will intercept and log these member functions by replacing the function pointers in the interface's vtable (the actual binary vector of function pointers used at run time) with its own. See the COM_INTERFACE_PTR Types section later in this section for more details on how Logger captures interfaces as they are handed out.

Type Definitions

Defining data types is the most important (and most tedious) part of manifest file development. The manifest language allows you to define human-readable labels for numeric values that are passed in or returned from a function.

For example, Winerror.h defines a type called "WinError" that is a list of error values returned by most Microsoft Win32 functions and their corresponding human-readable labels. This allows Logger and LogViewer to replace uninformative error codes with meaningful text.

You can also label individual bits within a bit mask to allow Logger and LogViewer to break a DWORD bit mask into its components.

There are 13 basic types supported by the manifest. They are listed in the following table.

Type	Length	Display Example
Pointer	4 bytes	0x001AF320
VOID	0 bytes	
BYTE	1 byte	0x32
WORD	2 bytes	0xA23
DWORD	4 bytes	-234323
BOOL	1 byte	TRUE
LPSTR	Length byte plus any number of characters	"Quick brown fox"
LPWSTR	Length byte plus any number of Unicode characters	"Jumped over the lazy dog"
GUID	16 bytes	{0CF774D0-F077-11D1-B1BC-00C04F86C324}
COM_INTERFACE_PTR	4 bytes	0x0203404A
value	Dependent on base type	ERROR_TOO_MANY_OPEN_FILES
mask	Dependent on base type	WS_MAXIMIZED WS_ALWAYSONTOP + lpRect nLeft 34 nRight 54 nTop 100 nBottom 300
struct	Dependent on size of encapsulated types	

Type definitions in manifest files work like C/C++ typedefs. For example, the following statement defines PLONG as a pointer to a LONG:

```
typedef LONG *PLONG;
```

Most basic typedefs have already been declared in Main.h. You should only have to add typedefs that are specific to your component. Structure definitions have the same format as C/C++ struct types.

There are four special types: value, mask, GUID, and COM_INTERFACE_PTR.

Value Types

A value is a basic type that is broken out into human-readable labels. Most function documentation only refers to the #define value of a particular constant used in a function. For example, most programmers are unaware of what the actual value is for all the codes returned by GetLastError, making it unhelpful to see a cryptic numerical value in LogViewer. The manifest value overcomes this by allowing value declarations like as in the following example:

```
value LONG ChangeNotifyFlags
{
#define SHCNF_IDLIST      0x0000      // LPITEMIDLIST
#define SHCNF_PATHA       0x0001      // path name
#define SHCNF_PRINTERA   0x0002      // printer friendly name
#define SHCNF_DWORD       0x0003      // DWORD
#define SHCNF_PATHW       0x0005      // path name
#define SHCNF_PRINTERW   0x0006      // printer friendly name
};
```

This declares a new type called "ChangeNotifyFlags" derived from LONG. If this is used as a function parameter, the human-readable aliases will be displayed instead of the raw numbers.

Mask Types

Similar to value types, a mask type is a basic type (usually a DWORD) that is broken out into human-readable labels for each of the bits that have meaning. Take the following example:

```
mask DWORD DirectDrawOptSurfaceDescCapsFlags
{
#define DDOSDCAPS_OPTCOMPRESSED          0x00000001
#define DDOSDCAPS_OPTREORDERED          0x00000002
#define DDOSDCAPS_MONOLITHICMIPMAP     0x00000004
};
```

This declares a new type derived from DWORD that, if used as a function parameter, will have the individual values broken out for the user in LogViewer. So, if the value is 0x00000005, LogViewer will display:

```
DDOSDCAPS_OPTCOMPRESSED | DDOSDCAPS_MONOLITHICMIPMAP
```

GUID Types

GUIDs are 16-byte globally-unique identifiers that are used extensively in COM. They are declared in two ways:

```
struct __declspec(uuid("00020400-0000-0000-C000-000000000046")) IDispatch,
```

or

```
class __declspec(uuid("11219420-1768-11D1-95BE-00609797EA4F")) ShellLinkObject;
```

The first method is used to declare an interface identifier (IID). When displayed by LogViewer, "IID_" is appended to the beginning of the display name. The second method is used to declare a class identifier (CLSID). LogViewer appends "CLSID_" to the beginning of the display name.

If a GUID type is a parameter to a function, LogViewer will compare the value against all declared IIDs and CLSIDs. If a match is found, it will display the IID friendly name. If not, it will display the 32-hexadecimal-character value in standard GUID notation.

COM_INTERFACE_PTR Types

The COM_INTERFACE_PTR type is the base type of a COM interface pointer. When you declare a COM interface, you are actually defining a new type that is derived from COM_INTERFACE_PTR. As such, a pointer to such a type can be a parameter to a function. If a COM_INTERFACE_PTR basic type is declared as an OUT parameter to a function and there is a separate parameter that has an [iid] label, Logger will compare the passed in IID against all declared GUIDs. If there is a match and a COM interface was declared that has the same name as the IID, Logger will hook all the functions in that interface and log them.

Here is an example:

```
STDAPI CoCreateInstance(
    REFCLSID rclsid,           //Class identifier (CLSID) of the object
    LPUNKNOWN pUnkOuter,       //Pointer to controlling IUnknown
    CLSCTX dwClsContext,      //Context for running executable code
    [iid] REFIID riid,         //Reference to the identifier of the interface
    [out] COM_INTERFACE_PTR * ppv
        = //Address of output variable that receives
          //the interface pointer requested in riid
);
```

In this example, *riid* has an [iid] modifier. This indicates to Logger that the pointer returned in *ppv* is a COM interface pointer for the interface identified by *riid*.

It is also possible to declare a function as follows:

```
DDRESULT DirectDrawCreateClipper( DWORD dwFlags, [out] LPDIRECTDRAWCLIPPER *lplpDDClipper, IUnknown *pUnkOuter );
```

In this example, LPDIRECTDRAWCLIPPER is defined as a pointer to the **IDirectDrawClipper** interface. Since Logger can identify which interface type is being returned in the *lplpDDClipper* parameter, there is no need for an [iid] modifier on any of the other parameters.

PLMDebug

PLMDebug.exe is a tool that enables you to use the Windows debugger to debug Windows app, which run under Process Lifecycle Management (PLM). With PLMDebug, you can take manual control of suspending, resuming, and terminating a Windows app.

Tip With Windows 10, version 1607 or later, you can use the UWP commands, such as .createpackageapp to debug UWP apps. For more information see [Debugging a UWP app using WinDbg](#).

Where to get PLMDebug

PLMDebug.exe is included in [Debugging Tools for Windows](#).

```
plmdebug /query [Package]
plmdebug /enableDebug Package [DebuggerCommandLine]
plmdebug /terminate Package
plmdebug /forceterminate Package
plmdebug /cleanterminate Package
plmdebug /suspend Package
plmdebug /resume Package
plmdebug /disableDebug Package
plmdebug /enumerateBgTasks Package
plmdebug /activateBgTaskTaskId
```

Parameters

Package

The full name of a package or the ID of a running process.

DebuggerCommandLine

A command line to open a debugger. The command line must include the full path to the debugger. If the path has blank spaces, it must be enclosed in quotes. The command line can also include arguments. Here are some examples:

```
"C:\Program Files (x86)\Windows Kits\8.0\Debuggers\x64\WinDbg.exe"
"\\"C:\Program Files\Debugging Tools for Windows (x64)\WinDbg.exe\" -server npipe:pipe=test"
```

/query [Package]

Displays the running state for an installed package. If *Package* is not specified, this command displays the running states for all installed packages.

/enableDebug Package [DebuggerCommandLine]

Increments the debug reference count for a package. The package is exempt from PLM policy if it has a non-zero debug reference count. Each call to **/enableDebug** must be paired with a call to **/disableDebug**. If you specify *DebuggerCommandLine*, the debugger will attach when any app from the package is launched.

/terminate Package

Terminates a package.

/forceTerminate Package

Forces termination of a package.

/cleanTerminate Package

Suspends and then terminates a package.

/suspend Package

Suspends a package.

/resume Package

Resumes a package.

/disableDebug Package

Decrements the debug reference count for a package.

/enumerateBgTasksPackage

Enumerate background task ids for a package.

/activateBgTaskTaskId

Activates a background task. Note that not all background tasks can be activated using PLMDbg.

Remarks

You must call **plmdebug /enableDebug** before you call any of the suspend, resume, or terminate functions.

The PLMDbg tool calls the methods of the [IPackageDebugSettings interface](#). This interface enables you to take manual control of the process lifecycle management for your apps. Through this interface (and as a result, through this tool), you can suspend, resume, and terminate your Windows app. Note that the methods of the [IPackageDebugSettings interface](#) apply to an entire package. Suspend, resume, and terminate affect all currently running apps in the package.

Examples

Example 1

Attach a debugger when your app is launched

Suppose you have an app named MyApp that is in a package named MyApp_1.0.0.0_x64_tnq5r49etfg3c. Verify that your package is installed by displaying the full names and running states all installed packages. In a Command Prompt window, enter the following command.

```
plmdebug /query
```

```
Package full name: 1daa103b-74e1-426d-8193-b6bc7ed66fed_1.0.0.0_x86_tnq5r49etfg3c
Package state: Terminated

Package full name: 41fb5f27-7b60-4f5e-8459-803673131dd9_1.0.0.0_x86_tnq5r49etfg3c
Package state: Suspended
...
Package full name: MyApp_1.0.0.0_x64_tnq5r49etfg3c
Package state: Terminated
...
```

Increment the debug reference count for your package, and specify that you want WinDbg to attach when your app is launched.

```
plmdebug /enableDebug MyApp_1.0.0.0_x64_tnq5r49etfg3c "C:\Program Files (x86)\Windows Kits\8.0\Debuggers\x64\WinDbg.exe"
```

When you launch your app, WinDbg will attach and break in.

When you have finished debugging, detach the debugger. Then decrement the debug reference count for your package.

```
plmdebug /disableDebug MyApp_1.0.0.0_x64_tnq5r49etfg3c
```

Example 2

Attach a debugger to an app that is already running

Suppose you want to attach WinDbg to MyApp, which is already running. In WinDbg, on the **File** menu, choose **Attach to a Process**. Note the process ID for MyApp. Let's say the process ID is 4816.

Increment the debug reference count for the package that contains MyApp.

plmdebug /enableDebug 4816

In WinDbg, in the **Attach to Process** dialog box, select process 4816, and click **OK**. WinDbg will attach to MyApp.

When you have finished debugging MyApp, detach the debugger. Then decrement the debug reference count for the package.

plmdebug /disableDebug 4816

Example 3

Manually suspend and resume your app

Suppose you want to manually suspend and resume your app. First, increment the debug reference count for the package that contains your app.

plmdebug /enableDebug MyApp_1.0.0.0_x64_tnq5r49etfg3c

Suspend the package. Your app's suspend handler is called, which can be helpful for debugging.

plmdebug /suspend MyApp_1.0.0.0_x64_tnq5r49etfg3c

When you have finished debugging, resume the package.

plmdebug /resume MyApp_1.0.0.0_x64_tnq5r49etfg3c

Finally, decrement the debug reference count for the package.

plmdebug /disableDebug MyApp_1.0.0.0_x64_tnq5r49etfg3c

Remote Tool

The Remote tool, Remote.exe, is a command-line tool that lets you run and control any console program from a remote computer.

Where to get the Remote tool

Remote.exe is included in [Debugging Tools for Windows](#).

Remote tool components

The Remote tool includes the following components:

- A server application that starts a console program and opens a named pipe for client connections.
- A client application that establishes a connection to a server. Commands typed on the client computer are sent to the console application on the server, and the remote client displays the output from the server's console window.
- A query feature that lists the remote sessions running on a server computer.

With the Remote tool, you can start multiple server sessions on a single computer where multiple clients can connect to each session. The sessions are limited only by the computer's resources.

This is an older tool that has been eclipsed by more sophisticated tools, primarily Remote Desktop. However, because it is simple and uses very few resources, it is still widely used, typically for remote debugging.

The Remote tool requires that commands be submitted on both the local and remote computers. As such, to use this tool on a computer without a local user, you must develop an alternate way to submit the commands and to restart the computer, if necessary.

The Remote tool can compromise security on your computer, because it does not authenticate users or use Microsoft Windows permissions. By default, any remote computer that can connect and provide the session name can use the named pipe that this tool creates, although you can use Remote tool options to include and exclude particular users and groups.

This section includes:

[Remote Tool Concepts](#)

[Remote Tool Commands](#)[Remote Tool Examples](#)

Related topics

[Tools Included in Debugging Tools for Windows](#)[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

Remote Tool Concepts

The following concepts are used in the Remote tool.

Client and Server

The Remote tool uses a client-server paradigm that avoids the words *local* and *remote*, which are relative terms that can be confusing when there are multiple users and multiple computers.

Commands that you type at the client and server computers appear in the Command Prompt windows of both computers.

The Server

The *server* is the computer on which the console program runs. The *Remote Server* is the instance of the Remote tool running on the server. The server establishes and names the remote session (named pipe), issues the command to start the console program, and determines who is permitted to connect to the session.

The Client

The *client* is a remote computer that sends commands to the console program. The *Remote Client* is the instance of the Remote tool running on the client computer. The client connects to the remote session that the server established and uses the remote session (named pipe) that the server created to send commands to the console program that runs on the server.

The Remote tool supports multiple clients in each remote session. Each client is running one Remote Client. All of the clients can send commands to the console program running on the server, and all of the clients can see the commands sent and output displayed.

Visible Session

When remote sessions are *visible*, they appear in the list of remote sessions on the computer. To display the list, use the [Remote Server query command \(/q\)](#).

By default, only debugger sessions are visible, that is, sessions in which the value of the *Command* parameter include the words **kd**, **dbg**, **remotedb**, **ntsd**, or **cdb**; otherwise, the session is not visible. The *Command* parameter is part of the Remote tool command on the server.

To make a session visible, add the **/v** parameter to the [Remote Server](#) command. To make a debugger session invisible, add the **/-v** parameter to the command.

For help with the Remote Server query command, see [Remote Server Query Command](#).

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

Remote Tool Commands

The Remote tool has a separate command syntax for the client and server sides of a session. Commands to start a server session must be entered first because they establish the communications pipe to which the client connects.

The Remote tool also has a query command and a separate set of commands that you use to communicate with the Remote tool (instead of the console program) during a remote session.

These commands are described in the following topics:

[Remote Server Syntax](#)[Remote Client Syntax](#)[Remote Server Query Command](#)[Remote Session Commands](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

Remote Server Syntax

To start the server side of the Remote tool, use the following syntax at the command line.

```
remote /s Command SessionName [/f Color] [/b] [/u User [/u User...]] [/ud User [/ud User...]] [/v | -v]
```

Parameters

/s

Starts a server session.

Command

Specifies the command that starts the console-based program. The command can include parameters. If the command includes spaces, enclose it in quotation marks.

SessionName

Assigns a name to the remote session. If the name includes spaces, enclose it in quotation marks. This parameter is not case-sensitive.

/f

Specifies the color of the text in the server command window.

/b

Specifies the background color of the server command window.

Color

Specifies a color. Valid values are black, blue, green, cyan, red, purple, yellow, white, lblack, lblue, lgreen, lred, lpurple, lyellow, and lwhite.

/u

Specifies users or groups that are permitted to connect to the remote session; by default, everyone is permitted. When you use this parameter, everyone is denied permission, except for the users and groups specified by the *User* subparameter.

/ud

Specifies users or groups that are denied permission to connect to the remote session; by default, no one is denied permission.

User

Specifies the name of a user or group in *[domain | computer]\{user | group}* format. When specifying users or groups on the local computer, omit the computer name.

/v

Makes a session visible. For more information, see [Visible Session](#).

By default, only debugger sessions are visible, that is, sessions in which the value of the *Command* parameter include the words **kd**, **dbg**, **remoteds**, **ntsd**, or **cdb**; otherwise, the session is not visible.

-v

Makes a remote debugger session invisible. For more information, see [Visible Session](#).

Comments

The *Command* and *SessionName* parameters must appear in the order shown on the syntax line.

To end a remote session, type **@k**. For more information, see [Remote Session Commands](#).

The Remote tool will not create a session that the current user does not have permission to join.

When starting more than one remote session on a single computer, open a new command window for each session. Also, use a different session name for each session. Because the session names are used to label the named pipes, they must be unique on the computer.

Sample Usage

```
remote /s "i386kd -v" TestSession
remote /s "cmd" "My Remote Session" /f white /b black /u Server01\Administrators
remote /s "ntsd -d -g -x" DebugIt /-v
remote /q Server01
```

Remote Client Syntax

To start the client side of the Remote tool, use the following syntax at the command line.

```
remote /c Server SessionName [/L Lines] [/f] [/b] [/k ColorFile]
```

Parameters

/c

Connects the client to a remote session.

Server

Specifies the computer name of the server that established the session.

SessionName

Specifies the name of the remote session. This parameter is not case-sensitive.

/L *Lines*

Specifies the number of lines from the console display that are sent to the client computer. The default is 200 lines. *Lines* is a decimal number.

/f

Specifies the color of the text in the server command window.

/b

Specifies the background color of the server command window.

Color

Specifies a color. Valid values are black, blue, green, cyan, red, purple, yellow, white, lblack, lblue, lgreen, lred, lpurple, lyellow, and lwhite.

/k *ColorFile*

Indicates the path (optional) and name of a formatted text file that specifies the colors for displaying the output on the client computer.

The color file associates keywords in the output with text colors. When the keywords appear in a line of output, the Remote tool applies the associated text color to that line. For the format of the file, see "Remarks".

/q *Computer*

Displays the remote sessions available on the specified computer. Only visible sessions appear in the list. (See **/v** in [Remote Server Syntax](#).)

Comments

The *Server* and *SessionName* parameters must appear in the order shown on the syntax line.

To disconnect from a remote session, type **@q**. For more information, see [Remote Session Commands](#).

Keyword Color File. The format of the keyword color file is as follows. The keyword interpreter is not case sensitive.

The keyword or phrase appears on a line by itself. The colors associated with that keyword appear by themselves on the following line, as shown in the syntax:

```
Keyword  
TextColor[, BackgroundColor]
```

For example, the following file directs Remote to display lines that include the word "error" in black text on a light red background; to display lines that include the word "warning" in light blue (on the default background), and lines that include the phrase "Windows Vista" in light green on the default background.

```
ERROR  
black, lred  
WARNING  
lblue  
Windows Vista  
lgreen
```

Sample Usage

```
remote /c Server01 TestSession
remote /c Domain1\ComputerA0 "cmd" "My Remote Session"
remote /c Server01 TestSession /L 50 /f black /b white /k c:\remote_file.txt
remote /q Server01
```

Remote Server Query Command

To display a list of available sessions on a local or Remote Server, use the following syntax.

```
remote /q Computer
```

Parameters

/q

Query. Displays the visible remote sessions on the specified computer.

Computer

Specifies the name of the computer. This parameter is required (even on the local computer).

Comments

The query display includes only server sessions; it does not display client connections to remote sessions.

The query display includes only visible sessions. There is no command to display invisible sessions.

The query display includes all visible sessions, including those that restrict users (/u and /ud). The user might not have permission to connect to all of the sessions in the list.

When there are no remote sessions running on the server, the Remote tool displays the following message:

```
No Remote servers running on \\Computer
```

However, when the only remote sessions running on the computer are invisible remote sessions, the Remote tool displays the following message:

```
No visible sessions on server \\Computer
```

[Send comments about this topic to Microsoft](#)

Remote Session Commands

Use the following commands to communicate with the Remote tool during a console session.

@H

Displays the session commands on server and client computers. Works on server and client computers.

@M *Message*

Displays the specified message on all server and client computers in the session. Works on server and client computers.

@P *Message*

Generates a pop-up window on the server computer with the specified message. On client computers, the message appears in the command window. Works on server and client computers.

@Q

Quit. Disconnects a client computer from the session. Works only on a client computer.

@K

Disconnects all clients and ends the remote session. Works only on a server computer.

Comments

For samples, see "Using the Session Commands" in [Remote Tool Examples](#).

In response to the session commands, the Remote tool displays a label with the day and time that the command was executed. The time for all events is displayed in the time zone of the server computer.

Remote Tool Examples

The examples in this section demonstrate the use of the Remote tool and show sample input and output.

Basic Server Command

The following command starts a remote session on the computer.

The command uses the /s parameter to indicate a server-side command. It uses the command, **cmd**, to start the Windows command shell (Cmd.exe), and names the session **test1**.

```
remote /s cmd test1
```

In response, the Remote tool starts the session and displays the command that clients would use to connect to the session.

```
*****  
*****      REMOTE      *****  
*****      SERVER      *****  
*****  
To Connect: Remote /C SERVER06 "test1"  
  
Microsoft Windows XP [Version 5.1.2600]  
(C) Copyright 1985-2001 Microsoft Corp.
```

Basic Client Command

The following command connects to a remote session on the Server01 computer. The command uses the /c parameter to indicate a client-side command. It specifies the name of the server computer, **Server01**, and the name of the session on that computer, **test1**.

```
remote /c server01 test1
```

In response, the Remote tool displays a message reporting that the client computer is connected to the session on the server computer. The message displays the name of the server computer and local user (**Server04 user1**).

```
*****  
*****      REMOTE      *****  
*****      CLIENT      *****  
*****  
Connected...  
  
Microsoft Windows XP [Version 5.1.2600]  
(C) Copyright 1985-2001 Microsoft Corp.  
  
C:\Program Files\Debugging Tools for Windows>  
**Remote: Connected to SERVER04 user1 [Tue 9:39 AM]
```

After the client connects to the server, the commands typed at the command prompt on the client and server computers appear on both displays..

For example, if you type **dir** at the command prompt of the client computer, the directory display appears in the Command Prompt window on both the client and server computers.

Using Server Options

The following server-side command starts a remote session with the NTSD debugger.

The command uses the /s parameter to indicate a server-side command. The next parameter, "**ntsd -d -v**", is the console command that starts the debugger, along with the debugger options. Because the console command includes spaces, it is enclosed in quotation marks. The command includes a name for the session, **debugit**.

The command uses the /u parameter to permit only administrators of the computer and a particular user, User03 in Domain01, to connect to the session. It uses the /f and /b options to specify black text (foreground) on a white background.

Finally, the command uses the /-v parameter to make the session invisible to user queries. Debugger sessions are visible by default.

```
remote /s "ntsd -d -v" DebugIt /u Administrators /u Domain01\User03  
/f black /b white /-v
```

In response, the Remote tool creates a session named **DebugIt** and starts NTSD with the specified parameters. The message indicates that only the specified users have permission to connect. It also changes the command window to the specified colors.

```
*****  
***** REMOTE *****  
***** SERVER *****  
*****  
  
Protected Server! Only the following users or groups can connect:  
    Administrators  
    Domain01\User03  
To Connect: Remote /C SERVER06 "debugit"  
  
Microsoft Windows XP [Version 5.1.2600]  
(C) Copyright 1985-2001 Microsoft Corp.
```

Using Client Options

The following command connects to the remote session with the NTSD debugger that was started in the previous example.

The command uses the /c parameter to indicate a client-side command. It specifies the name of the server computer, **server06**, and the name of the remote session, **debugit**.

The command also includes the /k parameter to specify the location of a keyword color file.

```
remote /c server06 debugit /k c:\remote_client.txt
```

The color file includes the following text:

Registry
white, blue
Token
red, white

This text instructs the Remote tool to display lines of output with the word "registry" (not case sensitive) in white text on a blue background and to display lines of output with the word "token" in red text on a white background.

In response, the Remote tool connects the client to the server session and displays the following message:

```
***** REMOTE *****  
***** CLIENT *****  
*****  
Connected...  
  
Microsoft Windows XP [Version 5.1.2600]
```

Lines of output with the word "registry" are displayed on the client computer in white text on a blue background, and lines of output with the word "kernel" in red text on a

Conclusions

The Remote tool includes a query parameter (`/q`) that displays a list of remote sessions on a particular computer. The display includes only visible sessions (debugger sessions

Querying server \\Server04

```
Querying server \\Server06  
Visible sessions on server Server06:  
  
ntsd [Remote /C SERVER06 "debug"] visible  
cmd [Remote /C SERVER06 "test"] visible
```

The display lists the visible sessions, the console programs running on those sessions (NTSD and the Command Prompt window), and the command that connects to the session. The session name appears in the command syntax in quotation marks.

The display does not show the permissions established for these sessions, if any. Therefore, the display might include sessions that you do not have permission to join.

Using the Session Commands

You can use the remote session commands at any time during a remote session.

The following command sends a message to all computers connected to the session

@M I think I found the problem.

As a result, the message appears in the Command Prompt windows of all computers in the session. The message includes the computer name and the day and time of the message.

```
@m I think I found the problem. [SERVER01 Wed 11:53 AM]
```

When the message is sent from the server computer, "Local" appears in the label instead of the computer name.

```
@m I think I found the problem. [Local Wed 11:52 AM]
```

The following command generates a pop-up message that appears on the server computer. On all client computers in the session, it writes a message to the Command Prompt window.

```
@P Did you see that?
```

On client computers, the pop-up message appears in the command window.

```
From SERVER02 [Wed 11:58 AM]
```

```
Did you see that?
```

The time that appears in the message label is always the time on the server computer, even if the client computer that sent the message is in a different time zone.

Ending a Remote Session

The following examples demonstrate how to use the remote session commands to disconnect a client computer from a session and to end a remote session. Only the server computer that started the remote session can end it.

To disconnect a client computer from a remote session, on the client computer, type **@q**.

In response, the following message appears on the client computer that disconnected.

```
*** SESSION OVER ***
```

On all other computers in the session, the Remote tool posts a message with the name of the computer and user who disconnected, and the day and time of the disconnect.

```
**Remote: Disconnected from SERVER04 User01 [Wed 12:01 PM]
```

To end a remote session, on the server computer, type **@k**. This command automatically disconnects the clients, and then ends the session.

TList

TList (Task List Viewer), Tlist.exe, is a command-line tool that displays the processes running on the local computer along with useful information about each process.

TList displays:

- All processes running on the computer, along with their process IDs (PIDs).
- A tree showing which processes created each process.
- Details of the process, including its virtual memory use and the command that started the process.
- Threads running in each process, including their thread IDs, entry points, last reported error, and thread state.
- The modules running in each process, including the version number, attributes, and virtual address of the module.

You can use TList to search for a process by name or PID, or to find all processes that have loaded a specified module.

In Windows XP and later versions of Windows, TList was replaced by TaskList (Tasklist.exe), which is described in Help and Support for those systems. TList is included in Debugging Tools for Windows to support users who do not have access to TaskList.

This section includes:

[TList Commands](#)

[TList Examples](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

TList Commands

The syntax of the TList command is as follows:

```
tlist [/p ProcessName | PID | Pattern | /t | /c | /e | /k | /m [Module] | /s | /v
```

Parameters

tlist

Without additional parameters, TList displays all running processes, their process identifiers (PIDs), and the title of the window in which they are running, if any.

/p ProcessName

Displays the process identifier (PID) of the specified process.

ProcessName is the name of the process (with or without file name extension), not a pattern.

If the value of *ProcessName* does not match any running process, TList displays -1. If it matches more than one process name, TList displays only the PID of the first matching process.

PID

Displays detailed information about the process specified by the PID. For information about the display, see the "Remarks" section below. To find a process ID, type **tlist** without additional parameter.

Pattern

Displays detailed information about all processes whose names or window titles match the specified pattern. Pattern can be a complete name or a regular expression.

/t

Displays a task tree in which each process appears as a child of the process that created it.

/c

Displays the command line that started each process.

/e

Displays the session identifier for each process.

/k

Displays the COM components active in each process.

/m Module

Lists tasks in which the specified DLL or executable module is loaded. Module can be a complete module name or a module name pattern.

/s

Displays the services that are active in each process.

/v

Displays details of running processes including the process ID, session ID, window title, command line, and the services running in the process.

Comments

In its detailed display of a process (**tlist PID** or **tlist Pattern**), TList displays the following information.

- Process ID, executable name, friendly name of the program.
- Current working directory (CWD).
- The command line that started the process (CmdLine).
- Current virtual address space values.
- Number of threads.
- A list of threads running in the process. For each thread, TList displays the thread ID (TID), the function that the thread is running, the address of the entry point, the address of the last reported error (if any), and the thread state.
- A list of the modules loaded for the process. For each module, TList displays the version number, attributes, virtual address of the module, and the module name.

When using the /e parameter, valid session identifiers appear in the process list only under the following conditions. Otherwise, the session identifier is zero (0).

- On Windows 2000 and Windows Server 2003, at least one user must be connected to a session other than the console session.
- On Windows XP, Fast User Switching must be enabled and more than one user must be connected to the non-console session.
- On Windows Vista, where all processes are associated with two Terminal Services sessions by default, at least one user must be connected to the non-console session.

TList Examples

The following examples demonstrate how to use TList.

Simplest TList Command (tlist)

Typing **tlist** without additional parameters displays a list of running processes, their process IDs (PIDs), and the title of the window in which they are running, if any.

```
c:\>tlist
0 System Process
4 System
308 smss.exe
356 csrss.exe
380 winlogon.exe      NetDDE Agent
424 services.exe
436 lsass.exe
604 svchost.exe
776 svchost.exe
852 spoolsv.exe
1000 clisvc1.exe
1036 InoRpc.exe
1064 InoRT.exe
1076 InoTask.exe
1244 WTSvc.exe
1492 Sysparse_com.exe OleMainThreadWndName
1980 explorer.exe      Program Manager
1764 launch32.exe     SMS Client User Application Launcher
1832 msmsgs.exe       MSBLSNetConn
2076 ctfmon.exe
2128 ISATRAY.EXE      IsaTray
4068 tlist.exe
```

Find a process ID (-p)

The following command uses the **-p** parameter and process name to find the process ID of the Explorer.exe (Explorer) process.

In response, TList displays the process ID of the Explorer process, 328.

```
c:\>tlist -p explorer
328
```

Find process details using PID

The following command uses the process ID of the process in which Explorer is running to find detailed information about the Explorer process.

```
c:\>tlist 328
```

In response, TList displays details of the Explorer process including the following elements:

- Process ID, executable name, program friendly name.
- Current working directory (CWD).
- The command line that started the process (CmdLine).
- Current virtual address space values.
- Number of threads.
- A list of threads running in the process. For each thread, TList displays the thread ID (TID), the function that the thread is running, the address of the entry point, the address of the last reported error (if any), and the thread state.
- A list of the modules loaded for the process. For each module, TList displays the version number, attributes, virtual address of the module, and the module name.

The following is an excerpt of the output resulting from this command.

```
328 explorer.exe      Program Manager
CWD:      C:\Documents and Settings\user01\
```

```
CmdLine: C:\WINDOWS\Explorer.EXE
VirtualSize: 90120 KB PeakVirtualSize: 104844 KB

5.1.2600.1106 shp 0x77C70000 GDI32.dll
5.1.2600.1255 shp 0x77D40000 USER32.dll
.... (module data deleted here)
```

Find multiple processes (Pattern)

The following command searches for processes by a regular expression that represents the process name or window name of one or more processes. In this example, the command searches for a process whose process name or window name begins with "ino."

```
c:\>tlist ino*
```

In response, TList displays process details for Inorpc.exe, Inort.exe, and Inotask.exe. For a description of the output, see the "Find process details using PID" subsection above.

Display a process tree (/t)

The following command displays a tree that represents the processes running on the computer. Processes appear as the children of the process that created them.

```
c:\>tlist /t
```

The resulting process tree follows. This tree shows, among other things, that the System (4) process created the Smss.exe process, which created Csrss.exe, Winlogon.exe, Lsass.exe and Rundll32.exe. Also, Winlogon.exe created Services.exe, which created all of the service-related processes.

```
System Process (0)
System (4)
  smss.exe (404)
    csrss.exe (452)
    winlogon.exe (476) NetDDE Agent
      services.exe (520)
        svchost.exe (700)
        svchost.exe (724)
        svchost.exe (864)
        svchost.exe (888)
        spoolsv.exe (996)
        scardsvr.exe (1040)
        alg.exe (1172)
        atievxx.exe (1200) ATI video bios poller
        InoRpc.exe (1248)
        InoRT.exe (1264)
        InoTask.exe (1308)
        mdm.exe (1392)
        dlhost.exe (2780)
        lsass.exe (532)
        rundll32.exe (500)
  explorer.exe (328) Program Manager
    WLANMON.exe (1728) TI Wireless LAN Monitor
    ISATRAY.EXE (1712) IsaTray
    cmmon32.exe (456)
    WINWORD.EXE (844) Tlist.doc - Microsoft Word
    dexplore.exe (2096) Platform SDK - CreateThread
```

Find process by module (/m)

The following command finds all of the processes running on the computer that load a particular DLL.

```
c:\>tlist /m
```

In response, TList displays process details for Inorpc.exe, Inort.exe, and Inotask.exe. For a description of the output, see the "Find process details using PID" subsection above.

UMDH

The User-Mode Dump Heap (UMDH) tool, Umdh.exe, analyzes the Microsoft Windows heap memory allocations for a given process. UMDH has the following modes.

- **Analyze a running process** ("Mode 1"). UMDH captures and analyzes the heap memory allocations for a process. For each allocation, UMDH displays the size of the allocation, the size of the overhead, the pointer to the allocation and the allocation stack. If a process has more than one active memory heap, UMDH captures all heaps. This analysis can be displayed in realtime or saved in a log file.
- **Analyze UMDH log files** ("Mode 2"). UMDH analyzes the log files it has previously created. UMDH can compare two logs created for the same process at different times, and display the calls in which the allocation size increased the most. This technique can be used to find memory leaks.

This section includes:

[Preparing to Use UMDH](#)

[UMDH Commands](#)

[Interpreting a UMDH Log](#)

[Interpreting a Log Comparison](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

Preparing to Use UMDH

You must complete the configuration tasks described in this section before using User-Mode Dump Heap (UMDH) to capture the heap allocations for a process. If the computer is not configured correctly, UMDH will not generate any results or the results will be incomplete or incorrect.

Create the user-mode stack trace database

Before using UMDH to capture the heap allocations for a process, you must configure Windows to capture stack traces.

To enable stack trace capturing for a process, use [GFlags](#) to set the **Create user mode stack trace database** flag for the process. This can be done by either of the following methods:

- In the GFlags graphical interface, choose the **Image File** tab. Type the process name, including the file name extension (for example, Notepad.exe). Press the **TAB** key, select **Create user mode stack trace database**, and then click **Apply**.
- Or, equivalently, use the following GFlags command line, where *ImageName* is the process name (including the file name extension):

gflags /i ImageName +ust

By default, the amount of stack trace data that Windows gathers is limited to 32 MB on an x86 processor, and 64 MB on an x64 processor. If you must increase the size of this database, choose the **Image File** tab in the GFlags graphical interface, type the process name, press the **TAB** key, check the **Stack Backtrace (Megs)** check box, type a value (in MB) in the associated text box, and then click **Apply**.

Note Increase this database only when necessary, because it may deplete limited Windows resources. When you no longer need the larger size, return this setting to its original value.

These settings affects all new instances of the program. It does not affect currently running instances of the program.

Access the Necessary Symbols

Before using UMDH, you must have access to the proper symbols for your application. UMDH uses the symbol path specified by the environment variable `_NT_SYMBOL_PATH`. Set this variable equal to a path containing the symbols for your application.

If you also include a path to Windows symbols, the analysis may be more complete. The syntax for this symbol path is the same as that used by the debugger; for details, see [Symbol Path](#).

For example, if the symbols for your application are located at C:\MyApp\Symbols, and you have installed the Windows symbol files to \\myshare\winsymbols, you would use the following command to set your symbol path:

```
set _NT_SYMBOL_PATH=c:\myapp\symbols;\myshare\winsymbols
```

As another example, if the symbols for your application are located at C:\MyApp\Symbols, and you want to use the public Microsoft symbol store for your Windows symbols, using C:\MyCache as your downstream store, you would use the following command to set your symbol path:

```
set _NT_SYMBOL_PATH=c:\myapp\symbols;srvc:\mycache*https://msdl.microsoft.com/download/symbols
```

Important Suppose you have two computers: a *logging computer* where you create a UMDH log and an *analysis computer* where you analyze the UMDH log. The symbol path on your analysis computer must point to the symbols for the version of Windows that was loaded on the logging computer at the time the log was made. Do not point the symbol path on the analysis computer to a symbol server. If you do, UMDH will retrieve symbols for the version of Windows that is running on the analysis computer, and UMDH will not display meaningful results.

Disable BSTR Caching

Automation (formerly known as OLE Automation) caches the memory used by BSTR strings. This can prevent UMDH from correctly determining the owner of a memory allocation. To avoid this problem, you must disable BSTR caching.

To disable BSTR caching, set the OANOCACHE environment variable equal to one (1). This setting must be made before launching the application whose allocations are to be traced.

Alternatively, you can disable BSTR caching from within the application itself by calling the .NET Framework **SetNoOaCache** function. If you choose this method, you should call this function early, because any BSTR allocations that have already been cached when **SetNoOaCache** is called will remain cached.

If you need to trace the allocations made by a service, you must set OANOCACHE as a system environment variable and then restart Windows for this setting to take effect.

On Windows 2000, in addition to setting OANOCACHE equal to 1, you must also install the hotfix available with [Microsoft Support Article 139071](#). This hotfix is not needed on Windows XP and later versions of Windows.

Find the Process ID

UMDH identifies the process by its process identifier (PID). You can find the PID of any running process by using Task Manager, Tasklist (Windows XP and later operating systems), or [TList](#).

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

UMDH Commands

UMDH has two different modes, each with its own command syntax and parameters:

- [Analyze a Running Process](#) - Displays all the heap allocation in a process.
- [Analyze UMDH Logs](#) - Compares the allocation list made at two different times for the same process. Analyzing the differences can help to identify memory leaks.

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

Analyze a Running Process

Use the following commands to record and analyze the heap memory allocations in a running process. This analysis focuses on stack traces.

```
umdh -p:PID [-f:LogFile] [-v[:MsgFile]] | [-g] | [-h]
```

Parameters

-p:PID

Specifies the process to analyze. *PID* is the process ID of the process. This parameter is required.

To find the PID of a running process, use Task Manager, Tasklist (Windows XP and later operating systems), or [TList](#).

-f:LogFile

Saves the log contents in a text file. By default, UMDH writes the log to stdout (command window).

LogFile specifies the path (optional) and name of the file. If you specify an existing file, UMDH overwrites the file.

Note If UMDH was not started in Administrator mode, or attempts to write to "protected" paths, it will be denied access.

-v[:MsgFile]

Verbose mode. Generates detailed informational and error messages. By default, UMDH writes these messages to stderr.

MsgFile specifies the path (optional) and name of a text file. When you use this variable, UMDH writes the verbose messages to the specified file, instead of to stderr. If you specify an existing file, UMDH overwrites the file.

-g

Logs the heap blocks that are not referenced by the process ("garbage collection").

-h

Displays help.

Comments

On Windows 2000, if UMDH is reporting errors finding the stack trace database, and you have enabled the **Create user mode stack trace database** option in [GFlags](#), you might have a symbol file conflict. To resolve it, copy the DBG and PDB symbol files for the application to the same directory, and try again.

Sample Usage

```
umdh -?  
umdh -p:2230  
umdh -p:2230 -f:dump_allocations.txt  
umdh -p:2230 -f:c:\Log1.txt -v:c:\Msg1.txt  
umdh -p:2230 -g -f:garbage.txt
```

[Send comments about this topic to Microsoft](#)

Analyze UMDH Logs

Use the following commands to analyze User-Mode Dump Heap (UMDH) logs that were created by running UMDH with the syntax described in [Analyze a Running Process](#). This analysis focuses on allocations, instead of stack traces.

You can analyze a single log file or compare logs from different runs to detect the changes in the program or driver's memory dump allocations over time.

```
umdh [-d] [-v] [-l] File1 [File2] [-h | ?]
```

Parameters

-d

Displays numeric data in decimal numbers. The default is hexadecimal.

-v

Verbose mode. Includes the traces, as well as summary information. The traces are most helpful when analyzing a single log file.

-l

Includes file names and line numbers in the log. (Please note that the parameter is the lowercased letter "L," not the number one.)

File1 [*File2*]

Specifies the UMDH log files to analyze.

UMDH creates log files when you run it in the [analyze a running process](#) mode and save the log content in a text file (-f).

When you specify one log file, UMDH analyzes the file and displays the function calls in each trace in descending order of bytes allocated.

When you specify two log files, UMDH compares the files and displays in descending order the function calls whose allocations have grown the most between the two trials.

-h | ?

Displays help.

Sample Usage

```
umdh dump.txt  
umdh -d -v dump.txt  
umdh dump1.txt dump2.txt
```

Remarks

Suppose you have two computers: a *logging computer* where you create a UMDH log and an *analysis computer* where you analyze the UMDH log. The symbol path on your analysis computer must point to the symbols for the version of Windows that was loaded on the logging computer at the time the log was made. Do not point the symbol path on the analysis computer to a symbol server. If you do, UMDH will retrieve symbols for the version of Windows that is running on the analysis computer, and UMDH will not display meaningful results.

[Send comments about this topic to Microsoft](#)

Interpreting a UMDH Log

User-Mode Dump Heap (UMDH) log files display the list of heap allocations in the process and the stacks where the allocations were made.

This example shows how to generate a log for a process that has ID 1204. The log is written to the file log1.txt.

```
umdh -p:1204 -f:log1.txt
```

The log file is not readable because the symbols are not resolved. UMDH resolves symbols when you analyze the log. This example shows how to analyze log1.txt and store the result in result.txt.

```
umdh -v log1.txt > result.txt
```

Symbol Files for Analyzing a Log File

Suppose you have two computers: a *logging computer* where you create a UMDH log and an *analysis computer* where you analyze the UMDH log. The symbol path on your analysis computer must point to the symbols for the version of Windows that was loaded on the logging computer at the time the log was made. Do not point the symbol path on the analysis computer to a symbol server. If you do, UMDH will retrieve symbols for the version of Windows that is running on the analysis computer, and UMDH will not display meaningful results.

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

Interpreting a Log Comparison

You can generate multiple User-Mode Dump Heap (UMDH) logs of the same process over time. Then, you can use UMDH to compare the logs and determine which call stack allocations have grown the most between trials.

For example, the following command directs UMDH to compare two UMDH logs, Log1.txt and Log2.txt, and redirects the output to a third file, Compare.txt.

```
umdh -v Log1.txt Log2.txt > Compare.txt
```

The resulting Compare.txt file lists the call stacks recorded in each log and, for each stack, displays the change in heap allocations between the log files.

For example, the following line from the file shows the change in allocation size for the functions in the call stack labeled "Backtrace00053."

In Log1.txt, the calls in the stack accounts for 40,432 (0x9DF0) bytes, but in Log2.txt, the same call stack accounts for 61,712 (0xF110) bytes, a difference of 21,280 (0x5320) bytes.

```
+ 5320 (f110 - 9df0) 3a allocs BackTrace00053
Total increase == 5320
```

Following is the stack for the allocation:

```
ntdll!RtlDebugAllocateHeap+0x000000FD
ntdll!RtlAllocateHeapSlowly+0x0000005A
ntdll!RtlAllocateHeap+0x00000080
MyApp! heap_alloc_base+0x00000069
MyApp! _heap_alloc_dbg+0x000001A2
MyApp! _nh_malloc_dbg+0x00000023
MyApp! _nh_malloc+0x00000016
MyApp!operator new+0x0000000E
MyApp!LeakyFunc+0x0000001E
MyApp!main+0x0000002C
MyApp!mainCRTStartup+0x000000FC
KERNEL32!BaseProcessStart+0x0000003D
```

An examination of the call stack shows that the **LeakyFunc** function is allocating memory by using the Visual C++ run-time library. If examination of the other log files shows that the allocation grows over time, you might be able to conclude that memory allocated from the heap is not being freed.

Symbol Files for Analyzing a Log File

Suppose you have two computers: a *logging computer* where you create a UMDH log and an *analysis computer* where you analyze the UMDH log. The symbol path on your analysis computer must point to the symbols for the version of Windows that was loaded on the logging computer at the time the log was made. Do not point the symbol path on the analysis computer to a symbol server. If you do, UMDH will retrieve symbols for the version of Windows that is running on the analysis computer, and UMDH will not display meaningful results.

USBView

USBView (Universal Serial Bus Viewer, Usbview.exe) is a Windows graphical user interface application that enables you to browse all USB controllers and connected USB devices on your computer. USBView works on all versions of Windows.

Where to get USBView

USBView is included in [Debugging Tools for Windows](#).

[USBView](#) is also available in the [Windows driver samples](#) repository on GitHub.

Using USBView

USBView can enumerate USB host controllers, USB hubs, and attached USB devices. It can also query information about the devices from the registry and through USB requests to the devices.

The main USBView window contains two panes. The left pane displays a connection-oriented tree view, enabling you to select any USB device.

The right pane displays the USB data structures that pertain to the selected USB device. These structures include Device, Configuration, Interface, and Endpoint Descriptors, as well as the current device configuration.

Tools Related to Debugging Tools for Windows

This section describes tools that are related to debugging but are not included in the Debugging Tools for Windows package.

[Application Verifier](#)

Monitor application actions while the application runs, subject the application to a variety of stresses and tests, and generate a report about potential errors in application execution or design. Application Verifier is included in the Windows Software Development Kit (SDK) for Windows 8. You can find information about downloading and installing the Windows SDK for Windows 8 [here](#).

[Windows Error Reporting](#)

You can configure Windows Error Reporting (WER) to write user-mode dump files when exceptions and other errors occur in user-mode code. WER is included in Windows Vista and later versions of Windows.

Application Verifier

Application Verifier (AppVerifier.exe) is a *dynamic verification* tool for user-mode applications. This tool monitors application actions while the application runs, subjects the application to a variety of stresses and tests, and generates a report about potential errors in application execution or design.

Application Verifier can detect errors in any user-mode applications that are not based on managed code, including user-mode drivers. It finds subtle programming errors that might be difficult to detect during standard application testing or driver testing.

You can use Application Verifier alone or in conjunction with a user-mode debugger. This tool runs on Microsoft Windows XP and later versions of Windows. The current user must be a member of the Administrators group on the computer.

Application Verifier is not included in Debugging Tools for Windows. Application Verifier is included in the Windows Software Development Kit (SDK). You can find information about downloading and installing the Windows SDK [here](#). After you install the Windows SDK, AppVerifier.exe and AppVerifier.chm will be in Windows\System32. To start Application Verifier, open a Command Prompt window and enter **appverif**.

The Application Verifier tool comes with its own documentation. To read the documentation, start Application Verifier, and from the **Help** menu, click **Help**, or press **F1**.

Source Code

This section contains the following topics.

- [Source Path](#)
- [Using a Source Server](#)
- [Creating Your Own Source Control System](#)
- [SrcSrv](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

Source Path

The *source path* specifies the directories where the C and C++ source files are located.

If you are debugging a user-mode process on the computer where the executable file was built, and if the source files are still in their original location, the debugger can automatically locate the source files.

In most other situations, you have to set the source path or load the individual source files.

When you are performing [remote debugging through the debugger](#), the debugging server uses the source path. If you are using WinDbg as your debugger, each debugging client also has its own *local source path*. All source-related commands access the source files on the local computer. You have to set the proper paths on any client or server that you want to use source commands.

This multiple-path system also enables a debugging client to use source-related commands without actually sharing the source files with other clients or with the server. This system is useful if there are private or confidential source files that one of the users has access to.

You can also load source files at any time, regardless of the source path.

Source Path Syntax

The debugger's source path is a string that consists of multiple directory paths, separated by semicolons.

Relative paths are supported. However, unless you always start the debugger from the same directory, you should add a drive letter or a network share before each path. Network shares are also supported.

Note If you are connected to a corporate network, the most efficient way to access source files is to use a source server. You can use a source server by using the **srv*** string within your source path. For more information about source servers, see [Using a Source Server](#).

Controlling the Source Path

To control the source path and local source path, you can do one of the following:

- Before you start the debugger, use the **_NT_SOURCE_PATH** [environment variable](#) to set the source path. If you try to add an invalid directory through this environment variable, the debugger ignores this directory.
- When you start the debugger, use the **-srcpath**[command-line option](#) to set the source path.

- Use the [.srcpath \(Set Source Path\)](#) command to display, set, change, or append to the source path. If you are using a source server, [.srcfix \(Use Source Server\)](#) is slightly easier.
- (WinDbg only) Use the [.lsrcpath \(Set Local Source Path\)](#) command to display, set, change, or append to the local source path. If you are using a source server, [.lsrcfix \(Use Local Source Server\)](#) is slightly easier. You can also use the WinDbg Command-Line with the parameter -lscrpath. For more information, see [WinDbg Command-Line Options](#).
- (WinDbg only) Use the [File | Source File Path](#) command or press CTRL+P to display, set, change, or append to the source path or the local source path.

You can also directly open or close a source file by doing one of the following:

- Use the [lsf \(Load or Unload Source File\)](#) command to open or close a source file.
- (WinDbg only) Use the [open \(Open Source File\)](#) command to open a source file.
- (WinDbg only) Use the [File | Open Source File](#) command or press CTRL+O to open a source file. You can also use the **Open source file (Ctrl+O)** button () on the toolbar.

Note When you use **File | Open Source File** (or its shortcut menu or button equivalents) to open a source file, the path of that file is automatically appended to the source path.

- (WinDbg only) Use the [File | Recent Files](#) command to open one of the four source files that you most recently opened in WinDbg.
- (WinDbg only) Use the [File | Close Current Window](#) command or click the **Close** button in the corner of the [Source window](#) to close a source file.

For more information about how to use source files, see [Debugging in Source Mode](#).

[Send comments about this topic to Microsoft](#)

Using a Source Server

A source server enables the debugger to automatically retrieve the source files that match the current target. To use a source server, you must be debugging binaries that have been source indexed at build time and whose source file locations are embedded in the PDB files.

Debugging Tools for Windows includes the source server [SrcSrv](#) (Srcsrv.exe).

Using SrcSrv with a Debugger

[SrcSrv](#) can be used with WinDbg, KD, NTSD, or CDB.

To use [SrcSrv](#) with the debugger, enter the following command to set the source path to `srv*`.

```
cmd  
.srcfix
```

You can get the same result by entering the following command.

```
cmd  
.srcpath srv*
```

Setting the source path to `srv*` tells the debugger that it should retrieve source files from locations specified in the target modules' symbol files.

If you want to use [SrcSrv](#) and also include a list of directories in your source path, use semicolons to separate `srv*` from any directories that are in the path.

For example:

```
cmd  
.srcpath srv*c:\someSourceCode
```

If the source path is set as shown in the preceding example, the debugger first uses [SrcSrv](#) to retrieve source files from locations specified in the target modules' symbol files. If SrcSrv is unable to retrieve a source file, the debugger attempts to retrieve it from `c:\someSourceCode`. Regardless of whether `srv*` is the first element in the path or appears later, the debugger always uses SymSrv before it searches any other directories listed in the path.

You can also use [.srcfix+](#) to append `srv*` to your existing source path, as shown in the following example.

```
cmd  
3: kd> .srcpath c:\mySource  
Source search path is: c:\mySource  
3: kd> .srcfix+  
Source search path is: c:\mySource;SRV*
```

If a source file is retrieved by the source server, it will remain on your hard drive after the debugging session is over. Source files are stored locally in the `src` subdirectory of the home directory (unlike the symbol server, the source server does not specify a local cache in the `srv*` syntax itself). The home directory defaults to the debugger installation directory; it can be changed by using the [.homedir](#) extension or by setting the `DBGHELP_HOMEDIR` environment variable. If this subdirectory does not already exist, it will be created.

If you use the [open \(Open Source File\)](#) command to open a new source file through [SrcSrv](#), you must include the -m Address parameter.

For information on how to index your sources, or if you plan to create your own source control provider module, see [SrcSrv](#).

Using AgeStore to Reduce the Cache Size

Any source files downloaded by [SrcSrv](#) will remain on your hard drive after the debugging session is over. To control the size of the source cache, the AgeStore tool can be used to delete cached files that are older than a specified date, or to reduce the contents of the cache below a specified size. For details, see [AgeStore](#).

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

SrcSrv

The SrcSrv tool (Srcsrv.dll) enables a client to retrieve the exact version of the source files that were used to build an application. Because the source code for a module can change between versions and over the course of years, it is important to look at the source code as it existed when the version of the module in question was built.

SrcSrv retrieves the appropriate files from source control. To use SrcSrv, the application must have been source-indexed.

This section includes:

- [Using SrcSrv](#)
- [Source Indexing](#)
- [Source Control Systems](#)
- [HTTP Sites and UNC Shares](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

Using SrcSrv

To use [SrcSrv](#) with WinDbg, KD, NTS, or CDB, verify that you have installed a recent version of the Debugging Tools for Windows package (version 6.3 or later). Then, include the text `srv*` in the source path, separated by semicolons from any directories that are also in the source path.

For example:

```
.srcpath srv*c:\someSourceCode
```

If the source path is set as shown in the preceding example, the debugger first uses [SrcSrv](#) to retrieve source files from locations specified in the target modules' symbol files. If SrcSrv is unable to retrieve a source file, the debugger attempts to retrieve it from `c:\someSourceCode`. Regardless of whether `srv*` is the first element in the path or appears later, the debugger always uses SymSrv before it searches any other directories listed in the path.

If a source file is retrieved by [SrcSrv](#), it remains on your hard drive after the debugging session is over. Source files are stored locally in the `src` subdirectory of the home directory (unlike the symbol server, the source server does not specify a local cache in the `srv*` syntax itself). The home directory defaults to the Debugging Tools for Windows installation directory; it can be changed by using the [!homedir](#) extension or by setting the `DBGHELP_HOMEDIR` environment variable. If the `src` subdirectory of the home directory does not already exist, it is created.

Debugging SrcSrv

If you experience any trouble extracting the source files from the debugger, start the debugger with the `-n` command-line parameter to view the actual source extraction commands along with the output of those commands. The `!sym noisy` command does the same thing, but you may have already missed important information from previous extraction attempts. This is because the debugger gives up trying to access source from version control repositories that appear to be unreachable.

Retrieving Source Files

If you use the [open \(Open Source File\)](#) command to open a new source file through [SrcSrv](#), you must include the `-m` Address parameter.

To facilitate the use of [SrcSrv](#) from tools other than the debuggers listed previously, the DbgHelp API provides access to SrcSrv functionality through the [SymGetSourceFile](#) function. To retrieve the name of the source file to be retrieved, call the [SymEnumSourceFiles](#) or [SymGetLineFromAddr64](#) function. For more details on the DbgHelp API, see the `dbghelp.chm` documentation, which can be found in the `sdk/help` subdirectory of the Debugging Tools for Windows installation directory, or see [Debug Help Library](#) on MSDN.

Using AgeStore to Reduce the Cache Size

Any source files downloaded by [SrcSrv](#) remain on your hard drive after the debugging session is over. To control the size of the source cache, the AgeStore tool can be used to delete cached files that are older than a specified date or to reduce the contents of the cache below a specified size. For details, see [AgeStore](#).

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

Source Indexing

Generally, binaries are source-indexed during the build process after the application has been built. The information needed by SrcSrv is stored in the .pdb files. SrcSrv currently supports the following source control systems:

- Perforce
- Microsoft Visual SourceSafe
- Microsoft Team Foundation Server

You can also create a custom script to index your code for a different source control system. One such module for Subversion is included in this package.

SrcSrv includes five tools that are used in the source indexing process:

[The Srcsrv.ini File](#)

[The Ssindex.cmd Script](#)

[The SrcTool Utility](#)

[The PDBStr Tool](#)

[The VSSDump Tool](#)

These tools are installed with Debugging Tools for Windows in the subdirectory srcsrv, and should remain installed in the same path as SrcSrv. The PERL scripts in these tools require PERL 5.6 or later.

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

The Srcsrv.ini File

The Srcsrv.ini file is the master list of all source control servers. Each entry has the following format:

MY SERVER=ServerInfo

When using Perforce, the *ServerInfo* consists of the full network path to the server, followed by a colon, followed by the port number it uses. For example:

MY SERVER=machine.corp.company.com:1666

Srcsrv.ini is a required file when you are actually source indexing a build using the modules shipped with this package. This entry creates an alias that is used to describe the server info. The value should be unique for every server that you support.

This file can also be installed on the computer running the debugger. When SrcSrv starts, it looks at Srcsrv.ini for values; these values override the information contained in the .pdb file. This enables users to configure a debugger to use an alternative source control server at debug time. However, if you manage your servers well and do not rename them, there should be no need to include this file with your client debugger installations.

This file also serves other purposes on the client side. For more information, see the sample Srcsrv.ini file installed with SrcSrv tools.

Using a Different Location or File Name

By default, SrcSrv uses as its master configuration file the file named Srcsrv.ini, located in the srcsrv subdirectory of the Debugging Tools for Windows installation directory.

You can specify a different file for configuration by setting the SRC_SRV_INI_FILE environment variable equal to the full path and file name of the desired file.

For example, if several people want to share a single configuration file, they could place it on a share accessible to all of their systems, and then set an environment variable like the following:

```
set SRC_SRV_INI_FILE=\ourserver\ourshare\bestfile.txt
```

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

The Ssindex.cmd Script

The Ssindex.cmd script builds the list of files checked into source control along with the version information of each file. It stores a subset of this information in the .pdb files generated when you built the application. SSIndex uses one of the following Perl modules to interface with source control:

- p4.pm (Perforce)
- vss.pm (Visual SourceSafe)
- tfs.pm (Team Foundation Servers)
- svn.pm (Subversion)

For more information, run Ssindex.cmd with the -? or -?? (verbose help) option or examine the script.

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

The SrcTool Utility

The SrcTool (Srctool.exe) utility lists all files indexed within the .pdb file. For each file, it lists the full path, source control server, and version number of the file. You can use this information for reference.

You can also use SrcTool to list the raw source file information from the .pdb file. To do this, use the -s switch on the command line.

SrcTool has other options as well. Use the ? switch to see them. Of most interest is that this utility can be used to extract all of the source files from version control. This is done with the -x switch.

Note Previous versions of this program created a directory called src below the current directory when extracting files. This is no longer the case. If you want the src directory used, you must create it yourself and run the command from that directory.

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

The PDBStr Tool

The PDBStr (Pdbstr.exe) tool is used by the indexing scripts to insert the version control information into the "srcsrv" alternative stream of the target .pdb file. It can also read any stream from a .pdb file. You can use this information to verify that the indexing scripts are working properly.

For more information, run PDBStr with the -? option.

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

The VSSDump Tool

The VSSDump (Vssdump.exe) tool is used by the indexing script for Microsoft Visual SourceSafe. It gathers the list of source files to be indexed. This program is also a valuable command-line utility that you can use to examine which files may be processed by the indexing script.

To prepare for source indexing, edit Srcsrv.ini so that it contains an entry for your version control server. This is an operation that you must do only once. Details are listed in the sample version Srcsrv.ini. You can use an environment variable or switch to the indexing script to denote the location of this file. However, it is best to put it in the same directory as the script because the contents of this file are intended to be global across all projects in your business or development system. This file serves to uniquely identify different version control servers. Note that you can provide a different version of this file to debuggers so that they look at a replicated copy of the version control server, which can be useful if you want to reduce traffic on the server.

To source-index a particular build, make certain that no source files are checked out on the build computer. If any files are checked out and edited, those changes are not reflected in the final source indexed .pdb files. Furthermore, if your build process includes a pre-compilation pass that generates source files from other files, you must check in those generated files to version control as part of the pre-compilation.

Upon completion of the build, set the current working directory to be the root of all source files and generated .pdb files. Then run SSIndex. You must specify what version control system you are using as a parameter. For example:

ssindex.cmd -server=vss

SSIndex accepts parameters that allow you to run the script from anywhere and to specify the location of the source files and .pdb files separately. This is most useful if the source is kept in another location from the output .pdb files. For example:

```
ssindex.cmd -server=vss -source=c:\source -symbols=c:\outputdir
```

These directories can also be specified with environment variables. Use the -? or -?? command line options for more information.

Here is an example of the output generated by this script:

```
C:\>ssindex.cmd -system=vss -
SSIndex.cmd [/option=<value> [...] [ModuleOptions] [/Debug]
General SrcSrv settings:
 NAME      SWITCH     ENV. VAR      Default
 -----
 1) srcsrv.ini    Ini      SRCSRV_INI      .\srcsrv.ini
 2) Source root   Source   SRCSRV_SOURCE   .
 3) Symbols root  Symbols  SRCSRV_SYMBOLS  .
 4) Control system System  SRCSRV_SYSTEM  <N/A>
 5) Save File (opt.) Save    SRCSRV_SAVE  <N/A>
 6) Load File (opt.) Load    SRCSRV_LOAD  <N/A>
Visual Source Safe specific settings:
 NAME      SWITCH     ENV. VAR      Default
 -----
 A) VSS Server   Server   SSDIR      <N/A>
 B) VSS Client   Client   SSROOT     <Current directory>
 C) VSS Project  Project  SSPROJECT  <N/A>
 D) VSS Label    Label    SSLABEL    <N/A>
Precedence is: Default, environment, cmdline switch. (ie. env overrides default,
switch overrides env).
Using '/debug' will turn on verbose output.
Use "SSIndex.cmd -??" for verbose help information.
See SrcSrv documentation for more information.
```

You can also use one of the provided wrapper scripts (Vssindex.cmd) to avoid specifying the version control system. The script source-indexes all .pdb files found in the current directory and below with version control information to locate all source files found in the current directory and below. You can specify different locations for these files by using environment variables and command-line switches.

Upon completion of the source indexing, you can test the output by running SrcTool on the .pdb files. This program displays data that indicates whether or not the .pdb file is source indexed. It also displays the specific information for every source file. Lastly, it displays the number of indexed sources and the number of sources that no indexing information was found for. It sets an %ERRORLEVEL% of -1 if the file is not source-indexed. Otherwise, it sets %ERRORLEVEL% to the number of indexed source files.

VSSDump can also be used independently to diagnose issues while source-indexing. The syntax is as follows:

vssdump.exe Options

Options can be any combination of the following options.

-a

Causes all projects to be searched, rather than restricting to the current project. This option may not be used with the **-p** option.

-p ProjectName

Causes *VSSDump* to restrict its search to the project specified by *ProjectName*. If this option is not present, the current project is used. This option may not be used with the **-a** option.

-d RootDirectory

Causes *VSSDump* to restrict its search to the root directory specified by *RootDirectory*. If this option is not present, the current directory is used.

-l Label

Causes *VSSDump* to list only those files with a label that matches that specified by *Label*.

VSSDump-v SharePath

Specifies that the location of the Virtual SourceSafe database is in *SharePath*. This option overrides the path specified in the SSDIR environment variable.

-r

Causes *VSSDump* to search subdirectories recursively.

-f

Causes *VSSDump* to list directories containing source files without listing the files themselves.

-i

Causes *VSSDump* to ignore the current directory and list the entire project. This option may not be used with **-r**.

-s

Causes *VSSDump* to format output for use with script files.

-c

Causes *VSSDump* to display only the Virtual SourceSafe configuration information.

Source Control Systems

SrcSrv includes provider modules for Visual SourceSafe (vss.pm), Perforce (p4.pm), Team Foundation Servers (tfn.pm), and Subversion (svn.pm). There is also a Concurrent Versions Systems (CVS) module for use with SrcSrv, but it has not been tested extensively. It is also possible to generate your own modules to support other versions of control systems.

This section includes:

[Using Visual SourceSafe](#)

[Debugging with Visual SourceSafe](#)

[Using CVS](#)

[Using Other Source Control Systems](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

Using Visual SourceSafe

Visual SourceSafe is an x86-based application, and the source indexing scripts and tools associated with it are installed only with the x86 package of Debugging Tools for Windows.

To successfully use Visual SourceSafe with SrcSrv, several defaults must be set in the system, including the Visual SourceSafe default database, the current project, and the working folder. You must also stamp each build project with a label so that Visual SourceSafe can differentiate between versions of a given file. Finally, you must set up any credentials needed to access the Visual SourceSafe database.

Visual SourceSafe Database

The default Visual SourceSafe database can be set with the SSDIR environment variable. If it is not set there, the SrcSrv indexing script can usually determine this from the registry. If it cannot, the script prompts you to set SSDIR. Regardless, this database value must be listed in your [Srcsrv.ini](#) file along with a simple alias to identify the database. More instructions can be found in the comments in Srcsrv.ini. You should add the entry in the variables section of Srcsrv.ini using the following syntax:

```
MYDATABASE=\\server\VssShare
```

Current Project

Visual SourceSafe uses the concept of a *current project*. The SrcSrv indexing script respects this value and limits processing to those source files that are part of the current project. To display the current project, use the following command:

```
ss.exe project
```

To change the current project, use the following command:

```
ss.exe cp Project
```

where *Project* indicates the current project. For example, to process all projects, set the current project to the root:

```
ss.exe cp $/
```

Working Folder

Visual SourceSafe projects are associated with *working folders*. A working folder is the location on the client computer that corresponds to the root of a project. However it is possible for such a computer to obtain and build source without a working folder being specified, usually when creating projects through the Visual Studio interface or by using the command:

```
ss.exe get -R
```

However, this mode of operation is incompatible with SrcSrv indexing. SrcSrv requires that a working folder be specified. To set the working folder, use the command:

```
ss.exe workfold Project Folder
```

where *Project* indicates the current project and *Folder* indicates the location corresponding to the root of the project.

Labels

Visual SourceSafe cannot determine what version of a file exists within the working directory of a build machine. Consequently, you must use labels to stamp the project with an identifier that is used to extract source files on the debugger client. Thus, before indexing, you must verify that all changes are checked into the database and then apply a label to the project. Labels can be applied using the command:

```
ss.exe label Project
```

where *Project* indicates the current project.

In the following example, the label "VERSION_3" is applied to a project called "\$/sdktools":

```
E:\nt\user>ss.exe label $/sdktools
Label for $/sdktools: VERSION_3
Comment for $/sdktools:
This is a comment.
```

After the label is applied, you can specify this label to the SrcSrv indexing script by setting the environment variable, SSLABEL, or by passing it as a command-line parameter, as in the following example:

```
vssindex.cmd -label=VERSION_3
```

Again, this label is required for SrcSrv indexing to work. Note that if you pass a label that does not exist in the project, it can take a long time for the script to complete and the results are of no use.

Credentials

If your Visual SourceSafe database requires a user and optional password for access, these values must be set through the SSUSER and SSPWD environment variables. This applies not only at the time the build is indexed, but also on the debugger client.

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

Debugging with Visual SourceSafe

In order for source files indexed using Visual SourceSafe to work properly with the debugger, you must configure your system properly.

If the Visual SourceSafe database requires a user and optional password for access, these values must be set using the SSUSER and SSPWD environment variables. Furthermore, the version of SrcSrv that ships with Visual Studio 2005 cannot detect whether Visual SourceSafe is prompting for credentials, which causes the application to stop responding.. Upgrade to the version of SrcSrv that ships with Debugging Tools for Windows to prevent this.

If Visual SourceSafe is not set in the path of your debugging computer, you can get around this by adding an entry to the [Srcsrv.ini](#) file that works with your debugger. When using a standard installation of Visual Studio, this file should be located in

```
%PROGRAMFILES%\Microsoft Visual Studio 8\Common7\IDE\srcsrv.ini
```

In the [trusted commands] section of Srcsrv.ini, add an entry of the form

```
ss.exe="Path"
```

where *Path* is the location of Ss.exe.

Using CVS

The CVS module for Source Server was developed using Concurrent Versions System (CVS) 1.11.17 (client). It has not been tested with any other versions of CVS. Furthermore, the current version of the module is a beta version.

CVSROOT

On the computer on which you source index the build, CVSROOT cannot contain password and user information. Use cvs.exe to set your credentialing information.

To prepare the [Srcsrv.ini](#) file for CVS indexing you must enter an alias for your repository that uniquely distinguishes it from any others in your network. This repository must match the value of CVSROOT in your environment. There is no need to set this value in the copy of Srcsrv.ini that you keep with your debugger clients because the alias is defined in the source indexed .pdb file.

Client Computer

The client computer that extracts files during debugging does not need a CVS sandbox or CVSROOT set. It does need CVS binaries in the path, and if the repository is locked, you must set the username and password with Cvs.exe.

Revision Tags

CVS is unable to extract a file by its version number. Instead, it must be done using what is known as a *tag*. When indexing a CVS-based system, you must ensure that all changes are checked into the repository and then apply a tag using the "cvs tag" command. Then, when indexing the file, make certain you use the "label" command-line parameter to specify the tag that you want to associate with the build you are indexing. You can achieve the same result by setting CVS_LABEL in the environment. Other values can be set from the environment or the command line. Use the -?? command-line option with SSIndex to examine your choices and to verify that all was configured correctly:

```
ssindex.cmd -system=cvs -??
```

Using Other Source Control Systems

Included in this package is Svn.pm. A closer look at this file shows how you can modify one of the existing scripts to support the Subversion Version Control system. Other control systems, even a control system that you create yourself, can be supported by creating your own provider module.

This section includes:

[Creating Your Own Provider Module](#)

[Creating Your Own Source Control System](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

Creating Your Own Provider Module

In general, to create your own provider module, you must implement the following set of interfaces.

\$module::SimpleUsage()

Purpose

Displays simple module usage information to STDOUT.

Parameters

None

Return Value

None

\$module::VerboseUsage()

Purpose

Displays in-depth module usage information to STDOUT.

Parameters

None

Return Value

None

\$objref = \$module::new(@CommandArguments)

Purpose

Initializes an instance of the provider module.

Parameters

@CommandArguments

All @ARGV arguments that are not recognized by ssindex.cmd as being general arguments.

Return Value

A reference that can be used in later operations.

\$Objref->GatherFileInfo(\$SourcePath,\$ServerHashReference)

Purpose

Enables the module to gather the required source-indexing information for the directory specified by the *\$SourcePath* parameter. The module should not assume that this entry is called only once for each object instance because SSIndex may call it multiple times for different paths.

Parameters

\$SourcePath

The local directory containing the source to be indexed.

\$ServerHashReference

A reference to a hash containing all of the entries from the specified Srcsrv.ini file.

Return Value

None

(\$VariableHashReference,\$FileEntry) = \$Objref->GetFileInfo(\$LocalFile)

Purpose

Provides the necessary information to extract a single, specific file from the source control system.

Parameters

\$LocalFile

A fully qualified file name.

Return Values

\$VariableHashReference

A hash reference of the variables necessary to interpret the returned *\$FileEntry*. Ssindex.cmd caches these variables for every source file used by a single debug file to reduce the amount of information written to the source index stream.

\$FileEntry

The file entry to be written to the source index stream to allow SrcSrv to extract this file from source control. The exact format of this line is specific to the source control system.

\$TextString= \$Objref->LongName()

Purpose

Provides a descriptive string to identify the source control system to the end user.

Parameters

None

Return Value

\$TextString

The descriptive name of the source control system.

@StreamVariableLines=\$Objref->SourceStreamVariables()

Purpose

Enables the source control system to add source-control-specific variables to the source stream for each debug file. The sample modules use this method for writing the required EXTRACT_CMD and EXTRACT_TARGET variables.

Parameters

None

Return Value

@StreamVariableLines

The list of entries for the source stream variables.

Creating Your Own Source Control System

This section enables you to understand how to prepare instrumentation scripts so that SrcSrv can be integrated into your build or version control system. The implementation is dependent on the language specification version that ships with SrcSrv.

Many of the specifics of how `Srcsrv.dll` is called by symbol handler code are discussed. However, this information is not static and will not become so in the future. No one should attempt to write code that calls `Srcsrv.dll` directly. This is reserved for `DbgHelp` or the Visual Studio products. Third-party vendors wanting to integrate such functionality into their products should use the `SymGetSourceFile` function. This function, along with others in the `DbgHelp` API, is described in the `DbgHelp` documentation, which can be found in the `sdk/help` subdirectory of the Debugging Tools for Windows installation directory.

This section includes:

Language Specification 1

Language Specification 2

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

Language Specification 1

The first version of SrcSrv works as follows. (This behavior may change in future versions.)

First, the client calls **SrcSrvInit** with the target path to be used as a base for all source file extractions. This path is stored in the special variable **TARG**.

When DbgHelp loads a module's .pdb file, it extracts the SrcSrv stream from the .pdb file and passes this data block to SrcSrv by calling **SrcSrvLoadModule**.

Then when DbgHelp needs to obtain a source file, it calls **SrvSrvGetFile** to retrieve a specified source file from version control.

SrcSrv reviews all the source file entries in the data block for an entry that matches exactly the requested source specification. This match is found in VAR1.

After SrcSrv finds the entry, it fills in the special variables (VAR1, VAR2, etc.) with the contents of this source file entry. Then the SRCSRVRG variable is resolved using these special variables.

The following shows how the SRCSRVTTRG variable is resolved using the special variables. We assume that the source path is still:

c:\proj\src\file.cpp*TOOLS PRJ*tools\mytool\src\file.cpp*3

Each line shows the resolution of one more special variable. The resolved variables are bold.

Notice how this generated target path is unique and does not allow two versions of the same file to be extracted to the same location.

SrcSrv now looks to see if the file is already there. If it is, SrcSrv returns the location to the caller. Otherwise, SrcSrv builds the execution command to extract the file by resolving SRCSRVCMD.

In the following example, each line shows the resolution of one more special variable. The resolved variables are bold.

```
DEPOT=/depot
WIN_SDKTOOLS= sserver.microsoft.com:4444
SRCSRVCMDS=%sdcmd%
SDCMD=sd.exe -p %fnvar(%var2%) print -o %srcsrvtrg% -q %depot%/%var3%#%var4%
sd.exe -p %fnvar(%WIN_SDKTOOLS%) print -o %srcsrvtrg% -q %depot%/%var3%#%var4%
sd.exe -p sserver.microsoft.com:4444 print -o %srcsrvtrg% -q %depot%/%var3%#%var4%
sd.exe -p sserver.microsoft.com:4444 print -o c:\src\WIN_SDKTOOLS\sdktools\debuggers\srcsrv\shell.cpp\3\shell.cpp -q %depot%/%var3%#%var4%
sd.exe -p sserver.microsoft.com:4444 print -o c:\src\WIN_SDKTOOLS\sdktools\debuggers\srcsrv\shell.cpp\3\shell.cpp -q //depot/%var3%#%var4%
sd.exe -p sserver.microsoft.com:4444 print -o c:\src\WIN_SDKTOOLS\sdktools\debuggers\srcsrv\shell.cpp\3\shell.cpp -q //depot/ sdktools\debu
```

Now SrcSrv executes this command. If the result of this command is a file in the expected location, this path is returned to the caller.

Note that if a variable cannot be resolved, an attempt is made to look it up as an OS environment variable. If that fails, the variable name is deleted from the text being processed.

Two consecutive percent sign characters are interpreted as a single percent sign.

Source Server Data Blocks

SrcSrv relies on two blocks of data within the .pdb file, the source file list and the data block.

The source file list is created automatically when a module is built. This list contains fully qualified paths to the source files used to build the module.

The data block is created during source indexing. At this time, an alternative stream named "srcsrv" is added to the .pdb file. The script that inserts this data is dependent on the specific build process and source control system in use.

The data block is divided into three sections: ini, variables, and source files. The data block has the following syntax.

```
SRCSRV: ini -----
VERSION=1
VERCTRL=<source_control_str>
DATETIME=<date_time_str>
SRCSRV: variables -----
SRCSRVTRG=%sdstrg%
SRCSRVCMD=%sdcmd%
SRCSENV=var1:string1\bvar2:string2
DEPOT=/depot
SDCMD=sd.exe -p %fnvar%(%var2%) print -o %srcsrvtrg% -q %depot%/%var3%#%var4%
SDTRG=%targ%\%var2%\%fnbksl%\%var3%\%var4%\%fnfile%\(%var1%
WIN_SDKTOOLS=sserver.microsoft.com:4444
SRCSRV: source files -----
<path1>*<var2>*<var3>*<var4>
<path2>*<var2>*<var3>*<var4>
<path3>*<var2>*<var3>*<var4>
<path4>*<var2>*<var3>*<var4>
SRCSRV: end -----
```

All text is interpreted literally, except for text enclosed in percent signs (%). Text enclosed in percent signs is treated as a variable name to be resolved recursively, unless it is one of the following functions:

%fnvar%()

The parameter text should be enclosed in percent signs and treated as a variable to be resolved.

%fnbksl%()

All forward slashes (/) in the parameter text should be replaced with backward slashes (\).

%fnfile%()

All path information in the parameter text should be stripped out, leaving only the file name.

The [ini] section of the data block contains variables that describe the requirements. The indexing script can add any number of variables to this section. The following are examples:

VERSION

The language specification version. This variable is required. If you develop a script based on the current language specification, set this value to 1. The SrcSrv client code does not attempt to execute any script that has a value greater than its own. Current versions of SrcSrv use a value of 2.

VERCTL

A string that describes the source version control system. This variable is optional.

DATETIME

A string that indicates the date and time the .pdb file was processed. This variable is optional.

The [variables] section of the data block contains variables that describe how to extract a file from source control. It can also be used to define commonly used text as variables to reduce the size of the data block.

SRCSRV

Describes how to build the target path for the extracted file. This is a required variable.

SRCSRVCMD

Describes how to build the command to extract the file from source control. This includes the name of the executable file and its command-line parameters. This is required if any extraction command must be executed.

SRCSENV

Lists environment variables to be created during the file extraction. This is a string. Separate multiple entries with a backspace character (\b). This is an optional variable.

SRCSRVERRCTRL

Specifies the version control system in use. For Perforce, this is perforce. For Visual SourceSafe, this is vss. For Team Foundation Server, this is tfs. This variable is

used to persist server errors. This is an optional variable.

SRCSRVERRDESC

Specifies the text to display when the version control client is unable to contact the server that contains the source files to extract. SrcSrv uses this value to check for connection problems. This is an optional variable.

SRCSRVERRVAR

Indicates which variable in a file entry corresponds to a version control server. It is used by SrcSrv to identify commands that do not work, based on previous failures. The format of the text is **varX** where *X* is the number of the variable being indicated. This is an optional variable.

The [source files] section of the data block contains an entry for each source file that has been indexed. The contents of each line are interpreted as variables with the names VAR1, VAR2, VAR3, and so on until VAR10. The variables are separated by asterisks. VAR1 must specify the fully qualified path to the source file as listed elsewhere in the .pdb file. For example:

```
c:\proj\src\file.cpp*TOOLS_PRJ*tools/mytool/src/file.cpp*3
```

is interpreted as follows:

```
VAR1=c:\proj\src\file.cpp
VAR2=TOOLS_PRJ
VAR3=tools/mytool/src/file.cpp
VAR4=3
```

In this example, VAR4 is a revision number. However, most source control systems support labeling files in such a way that the source state for a given build can be restored. Therefore, you could instead use the label for the build. The sample data block could be modified to contain a variable such as the following:

```
LABEL=BUILD47
```

Then, presuming the source control system uses the at sign (@) to indicate a label, you could modify the SRCSRVCMD variable as follows:

```
sd.exe -p %fnvar%(%var2%) print -o %srcsrvtrg% -q %depot%/%var3%@%label%
```

Handling Server Errors

Sometimes a client is unable to extract any files at all from a single version control server. This can be because the server is down and off the network or because the user does not have appropriate privileges to access the source. However, the time consumed attempting to get this source can slow things down significantly. In this situation, it is best to disable any attempt to extract from a source that has been proven to be unavailable.

Whenever SrcSrv fails to extract a file, it examines the output text produced by the command. If any part of this command contains an exact match for the contents of the SRCSRVERRDESC, all future commands to the same version control server are skipped. Note that you can define multiple error strings by adding numbers or arbitrary text to the end of the SRCSRVERRDESC variable name. Here is an example:

```
SRCSRVERRDESC=lime: server not found
SRCSRVERRDESC_2=pineapple: network error
```

The identity of the server is acquired from SRCSRVERRVAR. So if SRCSRVERRVAR contains "var2" and the file entry in the .pdb file looks like this:

```
c:\proj\src\file.cpp*TOOLS_PRJ*tools/mytool/src/file.cpp*3
```

all future attempts to obtain source using a file entry that contains "TOOLS_PRJ" in variable 2 are bypassed.

You can also add error indicators on the debugger client by editing [srsrv.ini](#). See the included sample version of srsrv.ini for details.

Language Specification 2

This package ships with a srsrv.dll that can operate without SRCSRVCMD being defined in the srsrv data stream of a .pdb file. While such capability is of no use for normal file extraction from source control systems, it is useful for direct access of files from a UNC share or HTTP site. See [HTTP Sites and UNC Shares](#) for more details.

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

HTTP Sites and UNC Shares

It is possible to set up a Web site that provides version-specific source to WinDbg using SrcSrv. Such a mechanism does not provide dynamic extraction of the source files from version control, but it is a valuable feature because it allows you to set the source path of WinDbg to a single unified path that provides source from many versions of

many modules, instead of having to set separate paths for each debugging scenario. This is not of interest to debugging clients that have direct access to the actual version control systems but can be of assistance to those wanting to provide secure HTTP-based access to source from remote locations. The Web sites in question can be secured through HTTPS and smart cards, if desired. This same technique can be used to provide source files through a simple UNC share.

This section includes:

[Setting Up the Web Site](#)

[Extracting Source Files](#)

[Modifying the Source Indexing Streams in a .pdb File](#)

[Using UNC Shares](#)

[Using HTTP Sites and UNC Shares in Conjunction with Regular Version Control](#)

[Send comments about this topic to Microsoft](#)

Setting Up the Web Site

Set up a Web site from which to share the source files and note the root directory of the site. Your source is then available from a site such as:

`https://SrcMachineName/source`

In order to make your source files accessible over the Internet, you must configure the directories containing the source files.

Begin by selecting the directory in which your indexed source resides. In our examples, we call this directory `c:\source` and the name of the server on the network `\SrcMachineName`. Permissions must be set so that users can access the site, and you must add the security groups that must access the source content over the network. The amount of security to enable varies from environment to environment. For some installations, this group is **Everyone**.

► **To set up the permissions for the directory:**

1. Open **Windows Explorer**.
2. Expand **My Computer**.
3. Expand the C: drive.
4. Right-click `c:\source` and choose **Sharing and Security**.
5. Check the **Share this folder** button.
6. Click the **Permissions** button.
7. Verify that the desired security groups have read access by adding them under **Group or user names** and checking the appropriate box.
8. Click **OK** to exit Permissions.
9. Click **OK** to exit Source Properties.

The source directory can now be used for debugging by another computer with a source path of `srv*\SrcMachineName\source`.

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

Extracting Source Files

To extract all of the source files from all the modules for which you want to provide source, use the command:

`srctool.exe -x`

This tool must be executed on .pdb files that have already been source-indexed for your version control system on a computer that has version control access. This places all source files into a common directory tree. Copy the contents of this tree to the root of the Web site. You can do this as often as you want on any new products or modules that you want to add. There is no worry about files overwriting each other because the directory tree structure keeps dissimilar files separated and uniquely accessible.

Walk

The Walk (Walk.cmd) script is included in Debugging Tools for Windows. This script searches recursively through a directory tree and executes any specified command on any file that matches a specified file mask. The syntax is:

```
walk.cmd FileMask Command
```

where *FileMask* specifies a file mask, with or without an accompanying starting directory, and *Command* specifies the command to be executed.

Here is an example that runs the srctool.exe file extraction command on all .pdb files in c:\symbols and its subdirectories:

```
walk.cmd c:\symbols\*.pdb srctool.exe -x
```

[Send comments about this topic to Microsoft](#)

Modifying the Source Indexing Streams in a .pdb File

For the debugger clients to use the SrcSrv Web site, the .pdb files must be modified to point to it. To do this manually, you make a copy of all the .pdb files, change them, and make them available from a separate location--usually the Web site itself.

Debugging Tools for Windows provides three files to assist in reconfiguring the .pdb files. The Cv2http.cmd and Cv2http.pl files extract the SrcSrv stream, modify it using a Perl script, and put the altered stream back in the .pdb file. The syntax is as follows:

```
cv2http.cmd PDB Alias URL
```

where *PDB* specifies the name of the .pdbfile to modify, *Alias* specifies the logical name to apply to your Web site, and *URL* specifies the full URL of the site. Note that the *Alias* parameter is stored in the PDB as a variable name that can be overridden on the debugger client in Scrsrv.ini, should you ever move the location of the Web site.

This script requires that all the standard SrcSrv tools be available in the path because it calls both SrcTool and PDBStr. Remember that Cv2http.pl is a Perl script and can be modified to meet your needs.

The third file, the Walk (walk.cmd) script, modifies an entire set of .pdb files. For example:

```
walk.cmd *.pdb cv2http.cmd HttpAlias https://source
```

The preceding command calls Cv2http.cmd on every .pdb file in a tree, using HttpAlias for the alias and https://server/source for the URL. For more details on Walk, see [Extracting Source Files](#).

After this command is executed on a tree of .pdb files, they are ready for installation into the Web site or whatever location in which you want to put them. Remember that you can use SrcTool and PDBStr to examine the changes to the .pdb files.

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

Using UNC Shares

The Cv2http.cmd, Cv2http.pl, and Walk (Walk.cmd) scripts are used to provide source files from a simple UNC share. The files Cv2http.cmd and Cv2http.pl extract the SrcSrv stream, modify it using a Perl script, and put the altered stream back in the .pdb file. The syntax is as follows:

```
cv2http.cmd PDB Alias SourceRoot
```

where *PDB* specifies the name of the .pdbfile to modify, *Alias* specifies the logical name to apply to your Web site, and *SourceRoot* specifies the root of the UNC share to which you extracted the source files. Note that the *Alias* parameter is stored in the PDB as a variable name that can be overridden on the debugger client in Scrsrv.ini, should you ever move the location of the Web site.

This script requires that all the standard SrcSrv tools be available in the path because it calls both SrcTool and PDBStr. Remember that Cv2http.pl is a Perl script and can be modified to meet your needs.

The third file, the Walk (walk.cmd) script, modifies an entire set of .pdb files. For example:

```
walk.cmd *.pdb cv2http.cmd SourceRoot \\server\share
```

The preceding command calls Cv2http.cmd on every .pdb file in a tree, using SourceRoot for the alias and \\server\\share for the UNC share. For more details on Walk, see [Extracting Source Files](#).

After this command is executed on a tree of .pdb files, they are ready for installation into the Web site or whatever location in which you want to put them. Remember that you can use SrcTool and PDBStr to examine the changes to the .pdb files.

Using HTTP Sites and UNC Shares in Conjunction with Regular Version Control

You may find that you must support your developers using the standard SrcSrv functionality that extracts files from version control but must also make source files available through a Web site or UNC share. This could happen if you have set up a test lab that does not have access to version control. It is possible to support both users using the same set of .pdb files.

First, extract the source files using SrcTool; see [Extracting Source Files](#) for details. Make the share available as either a Web site or UNC share. For the current purpose, you should not convert the .pdb files using the Cv2http.cmd script.

Now on the computers that will use the HTTP/UNC shares, edit the [Srsrv.ini](#) file that is in the debugger directory. In the variables section of the file, add the following three statements:

```
MY_SOURCE_ROOT=\\server\\share  
SRCSRVCMD=  
SRCRVTRG=%MY_SOURCE_ROOT%\%var2%\%var3%\%var4%\%fnfile%(%var1%)
```

You should replace \\server\\share with the root of the UNC share that you are providing or the URL of the Web site that contains the source files. You can also change MY_SOURCE_ROOT to be any alias you want to describe this location. With these exceptions, everything else should be entered exactly as described.

All debuggers set up in this fashion ignore the standard version control extraction instructions and instead access the source files from the location specified. Meanwhile, all debuggers without these items included in Srsrv.ini use the normal version control mechanism to extract source files.

Security Considerations

This section includes:

[Security Vulnerabilities](#)

[Secure Mode](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

Debug Privilege

The debug privilege allows someone to debug a process that they wouldn't otherwise have access to. For example, a process running as a user with the debug privilege enabled on its token can debug a service running as local system.

Debug privilege is a security policy setting that allows users to attach a debugger to a process or to the kernel. An administrator can modify a security policy for a user group to include or to remove this functionality. Developers who are debugging their own applications do not need this user privilege. Developers who are debugging system components or who are debugging remote components will need this user privilege. This user privilege provides complete access to sensitive and critical operating system components. By default, this property is enabled for users with Administrator rights. A user with Administrator privileges can enable this property for other user groups.

Modifying Debug Privilege for a Process

The following code example shows how to enable the debug privilege in your process. This enables you to debug other processes that you wouldn't have access to otherwise.

```
//  
// SetPrivilege enables/disables process token privilege.  
//  
BOOL SetPrivilege(HANDLE hToken, LPCTSTR lpszPrivilege, BOOL bEnablePrivilege)  
{  
    LUID luid;  
    BOOL bRet=FALSE;  
  
    if (LookupPrivilegeValue(NULL, lpszPrivilege, &luid))  
    {  
        TOKEN_PRIVILEGE tp;  
  
        tp.PrivilegeCount=1;  
        tp.Privileges[0].Luid=luid;  
        tp.Privileges[0].Attributes=(bEnablePrivilege) ? SE_PRIVILEGE_ENABLED: 0;  
        //  
        // Enable the privilege or disable all privileges.  
        //  
        if (AdjustTokenPrivileges(hToken, FALSE, &tp, NULL, (PTOKEN_PRIVILEGES)NULL, (PDWORD)NULL))  
        {  
            //
```

```

    // Check to see if you have proper access.
    // You may get "ERROR_NOT_ALL_ASSIGNED".
    //
    bRet=(GetLastError() == ERROR_SUCCESS);
}
}
return bRet;
}

```

The following example shows how to use this function:

```

HANDLE hProcess=GetCurrentProcess();
HANDLE hToken;

if (OpenProcessToken(hProcess, TOKEN_ADJUST_PRIVILEGES, &hToken))
{
    SetPrivilege(hToken, SE_DEBUG_NAME, TRUE);
    CloseHandle(hToken);
}

```

Security During Kernel-Mode Debugging

Security during kernel-mode debugging is never about protecting the *target* computer. The target is completely vulnerable to the debugger -- this is the very nature of debugging.

If a debugging connection was enabled during boot, it will remain vulnerable through the debugging port until its next boot.

However, you should be concerned about security on the *host* computer. In an ideal situation, the debugger runs as an application on your host computer, but does not interact with other applications on this computer. There are three possible ways in which security problems could arise:

- If you use corrupt or destructive extension DLLs, they could cause your debugger to take unexpected actions, possibly affecting the host computer.
- It is possible that corrupt or destructive symbol files could also cause your debugger to take unexpected actions, possibly affecting the host computer.
- If you are running a remote debugging session, an unexpected client might attempt to link to your server. Or perhaps the client you are expecting might attempt to perform actions that you do not anticipate.

If you want to prevent a remote user from performing actions on your host computer, use [Secure Mode](#).

For suggestions on how to guard against unexpected remote connections, see [Security During Remote Debugging](#).

If you are not performing remote debugging, you should still beware of bad symbol files and extension DLLs. Do not load symbols or extensions that you distrust!

Local Kernel Debugging

Only users who have debug privileges can start a local kernel debugging session. If you are the administrator of a machine that has multiple user accounts, you should be aware that any user with these privileges can start a local kernel debugging session, effectively giving them control of all processes on the computer -- and therefore giving them access to all peripherals as well.

© 2016 Microsoft. All rights reserved.

Security During User-Mode Debugging

When a user-mode debugger is active, it can effectively control any of the processes on the computer.

There are three possible ways in which security problems could arise during user-mode debugging:

- If you use corrupt or destructive extension DLLs, they could cause your debugger to take unexpected actions, possibly affecting applications other than your target.
- It is possible that corrupt or destructive symbol files could also cause your debugger to take unexpected actions, possibly affecting applications other than your target.
- If you are running a remote debugging session, an unexpected client might attempt to link to your server. Or perhaps the client you are expecting might attempt to perform actions that you do not anticipate.

For suggestions on how to guard against unexpected remote connections, see [Security During Remote Debugging](#). After a remote client has joined a user-mode debugging session, there is no way to restrict its access to processes on your computer.

If you are not performing remote debugging, you should still beware of bad symbol files and extension DLLs. do not load symbols or extensions that you distrust!

Security During Postmortem Debugging

Only an administrator can enable [postmortem debugging](#).

However, postmortem debugging is enabled for the entire system, not just for one user. Thus, after it has been enabled, any application crash will activate the debugger that has been chosen -- even if the current user does not have administrative privileges.

Also, a postmortem debugger inherits the same privileges as the application that crashed. Thus, if a Windows service such as CSRSS and LSASS crashes, the debugger will have very high-level privileges.

You should take this into account when choosing to enable postmortem debugging.

Security During Remote Debugging

There are two ways to increase security during remote debugging: by restricting who can connect to your session and by restricting the powers of someone who does connect.

Controlling Access to the Debugging Session

If you are performing [remote debugging through the debugger](#), or using a [process server](#) or [KD connection server](#), any computer on your local network can attempt to attach to your debugging session.

If you are using the TCP, 1394, COM, or named pipe protocols, you can require the Debugging Client to supply a password. However, this password is not encrypted during transmission, and therefore these protocols are not secure.

If you want your Debugging Server to be secure, you must use secure sockets layer (SSL) or secure pipe (SPIPE) protocol.

If you are performing [remote debugging through remote.exe](#), you can use the /u parameter to prohibit connections from unauthorized users.

Restricting the Powers of the Client

If you are setting up a kernel-mode debugging session, you can restrict the debugger's ability to interfere with the host machine by using [Secure Mode](#).

In user mode, Secure Mode is not available. You can stop an intrusive client from issuing Microsoft MS-DOS commands and running external programs by issuing the [.noshell \(Prohibit Shell Commands\)](#) command. However, there are many other ways for a client to interfere with your computer.

Note that both Secure Mode and [.noshell](#) will prevent both the Debugging Client and the Debugging Server from taking certain actions. There is no way to place a restriction on the client but not on the server.

Forgotten Process Servers

When you start a process server on a remote machine, the process server runs silently.

If you perform remote debugging through this process server and then end the session, the process server continues to run.

A forgotten process server is a potential target for an attack. You should always shut down an unneeded process server. Use the Kill.exe utility or Task Manager to terminate the process server.

© 2016 Microsoft. All rights reserved.

Secure Mode

When you are performing kernel-mode debugging, you can run the debugger in *Secure Mode*. This prevents the debugger from affecting the host computer, yet does not significantly decrease its freedom to debug the target computer.

Secure Mode is recommended if you are going to allow remote clients to join your debugging session.

This section includes:

[Features of Secure Mode](#)

[Activating Secure Mode](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

Features of Secure Mode

When Secure Mode is active, all commands that could be used to affect the *host* computer are deactivated, and there are some restrictions on symbol servers and debugger extensions.

The specific effects of Secure Mode are as follows:

- The [.attach \(Attach to Process\)](#), [.create \(Create Process\)](#), [.detach \(Detach from Process\)](#), [.abandon \(Abandon Process\)](#), [.kill \(Kill Process\)](#), [.list \(List Process IDs\)](#), [.dump \(Create Dump File\)](#), [.opendump \(Open Dump File\)](#), [.writemem \(Write Memory to File\)](#), [.netuse \(Control Network Connections\)](#), and [.quit_lock \(Prevent Accidental Quit\)](#) commands are not available.
- The [File | Attach to a Process](#), [File | Open Executable](#), [Debug | Detach Debuggee](#), [Debug | Stop Debugging](#), [File | Open Crash Dump](#) WinDbg menu commands are not available.
- The [.shell \(Command Shell\)](#) command is not available.
- Extension DLLs must be loaded from a local disk; they cannot be loaded from UNC paths.
- Only the two standard types of extension DLLs (wdbgexts.h and dbgeng.h) are permitted. Other types of DLLs cannot be loaded as extensions.
- If you are using a symbol server, there are several restrictions. Only SymSrv (symsrv.dll) is permitted; other symbol server DLLs will not be accepted. You may not use a downstream store for your symbols, and any existing downstream store will be ignored. HTTP and HTTPS connections are not permitted.

After it has been activated, Secure Mode cannot be turned off. For more information see, [Activating Secure Mode](#).

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

Activating Secure Mode

Secure Mode is only available for kernel-mode debugging. It must be activated before the debugging session has begun -- either on the debugger's command line, or when the debugger is completely dormant and is not yet being used as a server.

To activate Secure Mode, use one of the following methods:

- The [-secure command-line option](#)
- The [.secure 1](#) command
- The [.symopt+0x40000](#) command

If you have an existing kernel debugging session and need to discover whether you are already in Secure Mode, use the [.secure](#) command with no arguments. This will tell you the current status of Secure Mode.

After Secure Mode has been activated, it cannot be turned off. Even ending the debugging session will not turn it off. Secure Mode persists as long as the debugger itself is running.

x86 Architecture

The Intel x86 processor uses complex instruction set computer (CISC) architecture, which means there is a modest number of special-purpose registers instead of large quantities of general-purpose registers. It also means that complicated special-purpose instructions will predominate.

The x86 processor traces its heritage at least as far back as the 8-bit Intel 8080 processor. Many peculiarities in the x86 instruction are due to the backward compatibility with that processor (and with its Zilog Z-80 variant).

Microsoft Win32 uses the x86 processor in *32-bit flat mode*. This documentation will focus only on the flat mode.

Registers

The x86 architecture consists of the following unprivileged integer registers.

eax Accumulator
ebx Base register
ecx Count register
edx Double-precision register
esi Source index register
edi Destination index register
ebp Base pointer register
esp Stack pointer

All integer registers are 32 bit. However, many of them have 16-bit or 8-bit subregisters.

ax Low 16 bits of **eax**
bx Low 16 bits of **ebx**
cx Low 16 bits of **ecx**
dx Low 16 bits of **edx**
si Low 16 bits of **esi**

di Low 16 bits of **edi**
bp Low 16 bits of **ebp**
sp Low 16 bits of **esp**
al Low 8 bits of **eax**
ah High 8 bits of **ax**
bl Low 8 bits of **ebx**
bh High 8 bits of **bx**
cl Low 8 bits of **ecx**
ch High 8 bits of **cx**
dl Low 8 bits of **edx**
dh High 8 bits of **dx**

Operating on a subregister affects only the subregister and none of the parts outside the subregister. For example, storing to the **ax** register leaves the high 16 bits of the **eax** register unchanged.

When using the [? \(Evaluate Expression\)](#) command, registers should be prefixed with an "at" sign (@). For example, you should use ?@**ax** rather than ?**ax**. This ensures that the debugger recognizes **ax** as a register rather than a symbol.

However, the (@) is not required in the [r \(Registers\)](#) command. For instance, **r ax=5** will always be interpreted correctly.

Two other registers are important for the processor's current state.

eip instruction pointer
flags flags

The instruction pointer is the address of the instruction being executed.

The flags register is a collection of single-bit flags. Many instructions alter the flags to describe the result of the instruction. These flags can then be tested by conditional jump instructions. See [x86 Flags](#) for details.

Calling Conventions

The x86 architecture has several different calling conventions. Fortunately, they all follow the same register preservation and function return rules:

- Functions must preserve all registers, except for **eax**, **ecx**, and **edx**, which can be changed across a function call, and **esp**, which must be updated according to the calling convention.
- The **eax** register receives function return values if the result is 32 bits or smaller. If the result is 64 bits, then the result is stored in the **edx:eax** pair.

The following is a list of calling conventions used on the x86 architecture:

- Win32 ([__stdcall](#))

Function parameters are passed on the stack, pushed right to left, and the callee cleans the stack.

- Native C++ method call (also known as [thiscall](#))

Function parameters are passed on the stack, pushed right to left, the "this" pointer is passed in the **ecx** register, and the callee cleans the stack.

- COM ([__stdcall](#) for C++ method calls)

Function parameters are passed on the stack, pushed right to left, then the "this" pointer is pushed on the stack, and then the function is called. The callee cleans the stack.

- [__fastcall](#)

The first two DWORD-or-smaller arguments are passed in the **ecx** and **edx** registers. The remaining parameters are passed on the stack, pushed right to left. The callee cleans the stack.

- [__cdecl](#)

Function parameters are passed on the stack, pushed right to left, and the caller cleans the stack. The [__cdecl](#) calling convention is used for all functions with variable-length parameters.

Debugger Display of Registers and Flags

Here is a sample debugger register display:

```

eax=00000000 ebx=008b6f00 ecx=01010101 edx=ffffffff esi=00000000 edi=00465000
eip=77f9d022 esp=05cffc48 ebp=05cffc54 iopl=0 nv up ei ng nz na po nc
cs=001b ss=0023 ds=0023 es=0023 fs=0038 gs=0000 efl=00000286
  
```

In user-mode debugging, you can ignore the **iopl** and the entire last line of the debugger display.

x86 Flags

In the preceding example, the two-letter codes at the end of the second line are *flags*. These are single-bit registers and have a variety of uses.

The following table lists the x86 flags:

Flag Code	Flag Name	Value	Flag Status	Status Description
of	Overflow Flag	0 1	nfov	No overflow Overflow
df	Direction Flag	0 1	updn	Direction up Direction down
if	Interrupt Flag	0 1	diei	Interrupts disabled Interrupts enabled
sf	Sign Flag	0 1	plng	Positive (or zero) Negative
zf	Zero Flag	0 1	nzzr	Nonzero Zero
af	Auxiliary Carry Flag	0 1	naac	No auxiliary carry Auxiliary carry
pf	Parity Flag	0 1	pepo	Parity even Parity odd
cf	Carry Flag	0 1	nccy	No carry Carry
tf	Trap Flag			If tf equals 1, the processor will raise a STATUS_SINGLE_STEP exception after the execution of one instruction. This flag is used by a debugger to implement single-step tracing. It should not be used by other applications.
iopl	I/O Privilege Level			This is a two-bit integer, with values between zero and 3. It is used by the operating system to control access to hardware. It should not be used by applications.

When registers are displayed as a result of some command in the Debugger Command window, it is the *flag status* that is displayed. However, if you want to change a flag using the [r \(Registers\)](#) command, you should refer to it by the *flag code*.

In the Registers window of WinDbg, the flag code is used to view or alter flags. The flag status is not supported.

Here is an example. In the preceding register display, the **ng** appears. This means that the sign flag is currently set to 1. To change this, use the following command:

```
r sf=0
```

This sets the sign flag to zero. If you do another register display, the **ng** status code will not appear. Instead, the **pl** status code will be displayed.

The Sign Flag, Zero Flag, and Carry Flag are the most commonly-used flags.

Conditions

A *condition* describes the state of one or more flags. All conditional operations on the x86 are expressed in terms of conditions.

The assembler uses a one or two letter abbreviation to represent a condition. A condition can be represented by multiple abbreviations. For example, AE ("above or equal") is the same condition as NB ("not below"). The following table lists some common conditions and their meaning.

Condition Name Flags	Meaning
Z	ZF=1 Result of last operation was zero.
NZ	ZF=0 Result of last operation was not zero.
C	CF=1 Last operation required a carry or borrow. (For unsigned integers, this indicates overflow.)
NC	CF=0 Last operation did not require a carry or borrow. (For unsigned integers, this indicates overflow.)
S	SF=1 Result of last operation has its high bit set.
NS	SF=0 Result of last operation has its high bit clear.
O	OF=1 When treated as a signed integer operation, the last operation caused an overflow or underflow.
NO	OF=0 When treated as signed integer operation, the last operation did not cause an overflow or underflow.

Conditions can also be used to compare two values. The **cmp** instruction compares its two operands, and then sets flags as if subtracted one operand from the other. The following conditions can be used to check the result of **cmp value1, value2**.

Condition Name	Flags	Meaning after a CMP operation.
E	ZF=1	<i>value1 == value2</i> .
NE	ZF=0	<i>value1 != value2</i> .
GE	SF=OF	<i>value1 >= value2</i> .
NL	SF=OF	Values are treated as signed integers.
LE	ZF=1 or SF!=OF	<i>value1 <= value2</i> . Values are treated as signed integers.
NG	ZF=0 and SF=OF	<i>value1 > value2</i> . Values are treated as signed integers.
G		
NLE		
L	SF!=OF	<i>value1 < value2</i> . Values are treated as signed integers.
NGE		
AE	CF=0	<i>value1 >= value2</i> . Values are treated as unsigned integers.
NB	CF=0	<i>value1 >= value2</i> . Values are treated as unsigned integers.
BE	CF=1 or ZF=1	<i>value1 <= value2</i> . Values are treated as unsigned integers.
NA		

A NBE	CF=0 and ZF=0	<i>value1 > value2</i> . Values are treated as unsigned integers.
B NAE	CF=1	<i>value1 < value2</i> . Values are treated as unsigned integers.

Conditions are typically used to act on the result of a **cmp** or **test** instruction. For example,

```
cmp eax, 5
jz equal
```

compares the **eax** register against the number 5 by computing the expression (**eax** - 5) and setting flags according to the result. If the result of the subtraction is zero, then the **zf** flag will be set, and the **jz** condition will be true so the jump will be taken.

Data Types

- byte: 8 bits
- word: 16 bits
- dword: 32 bits
- qword: 64 bits (includes floating-point doubles)
- tword: 80 bits (includes floating-point extended doubles)
- oword: 128 bits

Notation

The following table indicates the notation used to describe assembly language instructions.

Notation	Meaning
r, r1, r2...	Registers
m	Memory address (see the succeeding Addressing Modes section for more information.)
#n	Immediate constant
r/m	Register or memory
r/#n	Register or immediate constant
r/m/#n	Register, memory, or immediate constant
cc	A condition code listed in the preceding Conditions section.
T	"B", "W", or "D" (byte, word or dword)
accT	Size <i>T</i> accumulator: al if <i>T</i> = "B", ax if <i>T</i> = "W", or eax if <i>T</i> = "D"

Addressing Modes

There are several different addressing modes, but they all take the form **T ptr [expr]**, where **T** is some data type (see the preceding Data Types section) and **expr** is some expression involving constants and registers.

The notation for most modes can be deduced without much difficulty. For example, **BYTE PTR [esi+edx*8+3]** means "take the value of the **esi** register, add to it eight times the value of the **edx** register, add three, then access the byte at the resulting address."

Pipelining

The Pentium is dual-issue, which means that it can perform up to two actions in one clock tick. However, the rules on when it is capable of doing two actions at once (known as *pairing*) are very complicated.

Because x86 is a CISC processor, you do not have to worry about jump delay slots.

Synchronized Memory Access

Load, modify, and store instructions can receive a **lock** prefix, which modifies the instruction as follows:

1. Before issuing the instruction, the CPU will flush all pending memory operations to ensure coherency. All data prefetches are abandoned.
2. While issuing the instruction, the CPU will have exclusive access to the bus. This ensures the atomicity of the load/modify/store operation.

The **xchg** instruction automatically obeys the previous rules whenever it exchanges a value with memory.

All other instructions default to nonlocking.

Jump Prediction

Unconditional jumps are predicted to be taken.

Conditional jumps are predicted to be taken or not taken, depending on whether they were taken the last time they were executed. The cache for recording jump history is limited in size.

If the CPU does not have a record of whether the conditional jump was taken or not taken the last time it was executed, it predicts backward conditional jumps as taken and forward conditional jumps as not taken.

Alignment

The x86 processor will automatically correct unaligned memory access, at a performance penalty. No exception is raised.

A memory access is considered aligned if the address is an integer multiple of the object size. For example, all BYTE accesses are aligned (everything is an integer multiple of 1), WORD accesses to even addresses are aligned, and DWORD addresses must be a multiple of 4 in order to be aligned.

The **lock** prefix should not be used for unaligned memory accesses.

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

x86 Instructions

In the lists in this section, instructions marked with an asterisk (*) are particularly important. Instructions not so marked are not critical.

On the x86 processor, instructions are variable-sized, so disassembling backward is an exercise in pattern matching. To disassemble backward from an address, you should start disassembling at a point further back than you really want to go, then look forward until the instructions start making sense. The first few instructions may not make any sense because you may have started disassembling in the middle of an instruction. There is a possibility, unfortunately, that the disassembly will never synchronize with the instruction stream and you will have to try disassembling at a different starting point until you find a starting point that works.

For well-packed **switch** statements, the compiler emits data directly into the code stream, so disassembling through a **switch** statement will usually stumble across instructions that make no sense (because they are really data). Find the end of the data and continue disassembling there.

Instruction Notation

The general notation for instructions is to put the destination register on the left and the source on the right. However, there can be some exceptions to this rule.

Arithmetic instructions are typically two-register with the source and destination registers combining. The result is stored into the destination.

Some of the instructions have both 16-bit and 32-bit versions, but only the 32-bit versions are listed here. Not listed here are floating-point instructions, privileged instructions, and instructions that are used only in segmented models (which Microsoft Win32 does not use).

To save space, many of the instructions are expressed in combined form, as shown in the following example.

* MOV r1, r/m/#n r1 = r/m/#n

means that the first parameter must be a register, but the second can be a register, a memory reference, or an immediate value.

To save even more space, instructions can also be expressed as shown in the following.

* MOV r1/m, r/m/#n r1/m = r/m/#n

which means that the first parameter can be a register or a memory reference, and the second can be a register, memory reference, or immediate value.

Unless otherwise noted, when this abbreviation is used, you cannot choose memory for both source and destination.

Furthermore, a bit-size suffix (8, 16, 32) can be appended to the source or destination to indicate that the parameter must be of that size. For example, r8 means an 8-bit register.

Memory, Data Transfer, and Data Conversion

Memory and data transfer instructions do not affect flags.

Effective Address

Load effective address.

* LEA r, m
(r = address of m)

For example, **LEA eax, [esi+4]** means **eax = esi + 4**. This instruction is often used to perform arithmetic.

Data Transfer

* MOV r1/m, r2/m/#n r1/m = r/m/#n

* MOVSX r1, r/m Move with sign extension.

* MOVZX **r1**, **r/m** Move with zero extension.

MOVSX and **MOVZX** are special versions of the **mov** instruction that perform sign extension or zero extension from the source to the destination. This is the only instruction that allows the source and destination to be different sizes. (And in fact, they must be different sizes.)

Stack Manipulation

The stack is pointed to by the **esp** register. The value at **esp** is the top of the stack (most recently pushed, first to be popped); older stack elements reside at higher addresses.

* PUSH	r/m/#n	Push value onto stack.
* POP	r/m	Pop value from stack.
PUSHFD		Push flags onto stack.
POPFD		Pop flags from stack.
PUSHAD		Push all integer registers.
POPAD		Pop all integer registers.
ENTER	#n, #n	Build stack frame.
* LEAVE		Tear down stack frame

The C/C++ compiler does not use the **enter** instruction. (The **enter** instruction is used to implement nested procedures in languages like Algol or Pascal.)

The **leave** instruction is equivalent to:

```
mov esp, ebp
pop ebp
```

Data Conversion

CBW	Convert byte (al) to word (ax).
CWD	Convert word (ax) to dword (dx:ax).
CWDE	Convert word (ax) to dword (eax).
CDQ	convert dword (eax) to qword (edx:eax).

All conversions perform sign extension.

Arithmetic and Bit Manipulation

All arithmetic and bit manipulation instructions modify flags.

Arithmetic

* ADD r1/m, r2/m/#n	r1/m += r2/m/#n
ADC r1/m, r2/m/#n	r1/m += r2/m/#n + carry
* SUB r1/m, r2/m/#n	r1/m -= r2/m/#n
SBB r1/m, r2/m/#n	r1/m -= r2/m/#n + carry
* NEG r1/m	r1/m = -r1/m
* INC r/m	r/m += 1
* DEC r/m	r/m -= 1
* CMP r1/m, r2/m/#n	Compute r1/m - r2/m/#n

The **cmp** instruction computes the subtraction and sets flags according to the result, but throws the result away. It is typically followed by a conditional **jmp** instruction that tests the result of the subtraction.

MUL r/m8	ax = al * r/m8
MUL r/m16	dx:ax = ax * r/m16
* MUL r/m32	edx:eax = eax * r/m32
IMUL r/m8	ax = al * r/m8
IMUL r/m16	dx:ax = ax * r/m16
* IMUL r/m32	edx:eax = eax * r/m32
* IMUL r1, r2/m	r1 *= r2/m
* IMUL r1, r2/m, #n	r1 = r2/m * #n

Unsigned and signed multiplication. The state of flags after multiplication is undefined.

```
DIV r/m8 (ah, al) = (ax % r/m8, ax / r/m8)
DIV r/m16 (dx, ax) = dx:ax / r/m16
```

* DIV r/m32 (edx, eax) = edx:eax / r/m32
 IDIV r/m8 (ah, al) = ax / r/m8
 IDIV r/m16 (dx, ax) = dx:ax / r/m16
 * IDIV r/m32 (edx, eax) = edx:eax / r/m32

Unsigned and signed division. The first register in the pseudocode explanation receives the remainder and the second receives the quotient. If the result overflows the destination, a division overflow exception is generated.

The state of flags after division is undefined.

* SETcc r/m8 Set r/m8 to 0 or 1

If the condition *cc* is true, then the 8-bit value is set to 1. Otherwise, the 8-bit value is set to zero.

Binary-coded Decimal

You will not see these instructions unless you are debugging code written in COBOL.

DAA Decimal adjust after addition.

DAS Decimal adjust after subtraction.

These instructions adjust the **al** register after performing a packed binary-coded decimal operation.

AAA ASCII adjust after addition.

AAS ASCII adjust after subtraction.

These instructions adjust the **al** register after performing an unpacked binary-coded decimal operation.

AAM ASCII adjust after multiplication.

AAD ASCII adjust after division.

These instructions adjust the **al** and **ah** registers after performing an unpacked binary-coded decimal operation.

Bits

* AND r1/m, r2/m/#n r1/m = r1/m and r2/m/#n
 * OR r1/m, r2/m/#n r1/m = r1/m or r2/m/#n
 * XOR r1/m, r2/m/#n r1/m = r1/m xor r2/m/#n
 * NOT r1/m r1/m = bitwise not r1/m
 * TEST r1/m, r2/m/#n Compute r1/m and r2/m/#n

The **test** instruction computes the logical AND operator and sets flags according to the result, but throws the result away. It is typically followed by a conditional jump instruction that tests the result of the logical AND.

* SHL r1/m, cl/#n r1/m <= cl/#n
 * SHR r1/m, cl/#n r1/m >= cl/#n zero-fill
 * SAR r1/m, cl/#n r1/m >= cl/#n sign-fill

The last bit shifted out is placed in the carry.

SHLD r1, r2/m, cl/#n Shift left double.

Shift **r1** left by **cl/#n**, filling with the top bits of **r2/m**. The last bit shifted out is placed in the carry.

SHRD r1, r2/m, cl/#n Shift right double.

Shift **r1** right by **cl/#n**, filling with the bottom bits of **r2/m**. The last bit shifted out is placed in the carry.

ROL r1, cl/#n Rotate **r1** left by **cl/#n**.

ROR **r1, cl/#n** Rotate **r1** right by **cl/#n**.
 RCL **r1, cl/#n** Rotate **r1/C** left by **cl/#n**.
 RCR **r1, cl/#n** Rotate **r1/C** right by **cl/#n**.

Rotation is like shifting, except that the bits that are shifted out reappear as the incoming fill bits. The C-language version of the rotation instructions incorporate the carry bit into the rotation.

BT **r1, r2/#n** Copy bit **r2/#n** of **r1** into carry.
 BTS **r1, r2/#n** Set bit **r2/#n** of **r1**, copy previous value into carry.
 BTC **r1, r2/#n** Clear bit **r2/#n** of **r1**, copy previous value into carry.

Control Flow

- * Jcc dest Branch conditional.
- * JMP dest Jump direct.
- * JMP r/m Jump indirect.
- * CALL dest Call direct.
- * CALL r/m Call indirect.

The **call** instruction pushes the return address onto the stack then jumps to the destination.

* RET #n Return

The **ret** instruction pops and jumps to the return address on the stack. A nonzero **#n** in the **RET** instruction indicates that after popping the return address, the value **#n** should be added to the stack pointer.

LOOP Decrement **ecx** and jump if result is nonzero.
 LOOPZ Decrement **ecx** and jump if result is nonzero and **zf** was set.
 LOOPNZ Decrement **ecx** and jump if result is nonzero and **zf** was clear.
 JCXZ Jump if **ecx** is zero.

These instructions are remnants of the x86's CISC heritage and in recent processors are actually slower than the equivalent instructions written out the long way.

String Manipulation

- * MOVST Move **T** from **esi** to **edi**.
- CMPST Compare **T** from **esi** with **edi**.
- SCAST Scan **T** from **edi** for acc**T**.
- LODST Load **T** from **esi** into acc**T**.
- * STOST Store **T** to **edi** from acc**T**.

After performing the operation, the source and destination register are incremented or decremented by sizeof(**T**), according to the setting of the direction flag (up or down).

The instruction can be prefixed by **REP** to repeat the operation the number of times specified by the **ecx** register.

The **rep mov** instruction is used to copy blocks of memory.

The **rep stos** instruction is used to fill a block of memory with acc**T**.

Flags

- LAHF Load **ah** from flags.
- SAHF Store **ah** to flags.
- STC Set carry.
- CLC Clear carry.
- CMC Complement carry.
- STD Set direction to *down*.
- CLD Set direction to *up*.
- STI Enable interrupts.
- CLI Disable interrupts.

Interlocked Instructions

XCHG **r1, r/m** Swap **r1** and **r/m**.
 XADD **r1, r/m** Add **r1** to **r/m**, put original value in **r1**.
 CMPXCHG **r1, r/m** Compare and exchange conditional.

The **cmpxchg** instruction is the atomic version of the following:

```
    cmp      accT, r/m
    jz      match
    mov      accT, r/m
    jmp      done
match:
    mov      r/m, r1
done:
```

Miscellaneous

INT #n Trap to kernel.
 BOUND **r, m** Trap if **r** not in range.
 * NOP No operation.
 XLATB **al** = [**ebx** + **al**]
 BSWAP **r** Swap byte order in register.

Here is a special case of the **int** instruction.

INT 3 Debugger breakpoint trap.

The opcode for **INT 3** is 0xCC. The opcode for **NOP** is 0x90.

When debugging code, you may need to patch out some code. You can do this by replacing the offending bytes with 0x90.

Idioms

- * XOR **r, r** = 0
- * TEST **r, r** Check if **r** = 0.
- * ADD **r, r** Shift **r** left by 1.

Annotated x86 Disassembly

The following section will walk you through a disassembly example.

Source Code

The following is the code for the function that will be analyzed.

```
HRESULT CUserView::CloseView(void)
{
    if (_m_fDestroyed) return S_OK;

    BOOL fViewObjectChanged = FALSE;
    ReleaseAndNull(&m_pdtgt);

    if (_m_psv) {
        _m_psb->EnableModelessSB(FALSE);
        if(_m_pws) _m_pws->ViewReleased();

        IShellView* psv;

        HWND hwndCapture = GetCapture();
        if (hwndCapture && hwndCapture == _m_hwnd) {
            SendMessage(_m_hwnd, WM_CANCELMODE, 0, 0);
        }

        _m_fHandsOff = TRUE;
        _m_fRecursing = TRUE;
        NotifyClients(_m_psv, NOTIFY_CLOSING);
        _m_fRecursing = FALSE;
    }
}
```

```

m_psv->UIActivate(SVUIA_DEACTIVATE);

psv = m_psv;
m_psv = NULL;

ReleaseAndNull(&_pctView);

if (_pvo) {
    IAdviseSink *pSink;
    if (SUCCEEDED(_pvo->GetAdvise(NULL, NULL, &pSink)) && pSink) {
        if (pSink == (IAdviseSink *)this)
            _pvo->SetAdvise(0, 0, NULL);
        pSink->Release();
    }
}

fViewObjectChanged = TRUE;
ReleaseAndNull(&_pvo);
}

if (psv) {
    psv->SaveViewState();
    psv->DestroyViewWindow();
    psv->Release();
}

m_hwndView = NULL;
m_fHandsOff = FALSE;

if (_pcache) {
    GlobalFree(_pcache);
    _pcache = NULL;
}

_m_psbs->EnableModelessSB(TRUE);

CancelPendingActions();
}

ReleaseAndNull(&_psf);

if (fViewObjectChanged)
    NotifyViewClients(DVASPECT_CONTENT, -1);

if (_pszTitle) {
    LocalFree(_pszTitle);
    _pszTitle = NULL;
}

SetRect(&_m_rcBounds, 0, 0, 0, 0);
return S_OK;
}
}

```

Assembly Code

This section contains the annotated disassembly example.

Functions which use the **ebp** register as a frame pointer start out as follows:

```

HRESULT CUserView::CloseView(void)
SAMPLE!CUserView__CloseView:
71517134 55          push    ebp
71517135 8bec         mov     ebp,esp

```

This sets up the frame so the function can access its parameters as positive offsets from **ebp**, and local variables as negative offsets.

This is a method on a private COM interface, so the calling convention is **_stdcall**. This means that parameters are pushed right to left (in this case, there are none), the "this" pointer is pushed, and then the function is called. Thus, upon entry into the function, the stack looks like this:

```

[esp+0] = return address
[esp+4] = this

```

After the two preceding instructions, the parameters are accessible as:

```

[ebp+0] = previous ebp pushed on stack
[ebp+4] = return address
[ebp+8] = this

```

For a function that uses **ebp** as a frame pointer, the first pushed parameter is accessible at **[ebp+8]**; subsequent parameters are accessible at consecutive higher DWORD addresses.

```

71517137 51          push    ecx
71517138 51          push    ecx

```

This function requires only two local stack variables, so a **sub esp, 8** instruction. The pushed values are then available as **[ebp-4]** and **[ebp-8]**.

For a function that uses **ebp** as a frame pointer, stack local variables are accessible at negative offsets from the **ebp** register.

```

71517139 56          push    esi

```

Now the compiler saves the registers that are required to be preserved across function calls. Actually, it saves them in bits and pieces, interleaved with the first line of actual code.

```
7151713a 8b7508      mov     esi,[ebp+0x8]    ; esi = this
7151713d 57          push    edi             ; save another registers
```

It so happens that CloseView is a method on ViewState, which is at offset 12 in the underlying object. Consequently, **this** is a pointer to a ViewState class, although when there is possible confusion with another base class, it will be more carefully specified as (*ViewState**)**this**.

```
if (m_fDestroyed)
7151713e 33ff         xor     edi,edi        ; edi = 0
```

XORing a register with itself is a standard way of zeroing it out.

```
71517140 39beac000000  cmp     [esi+0xac],edi    ; this->m_fDestroyed == 0?
71517146 7407         jz      NotDestroyed (7151714f) ; jump if equal
```

The **cmp** instruction compares two values (by subtracting them). The **jz** instruction checks if the result is zero, indicating that the two compared values are equal.

The cmp instruction compares two values: a subsequent j instruction jumps based on the result of the comparison.

```
return S_OK;
71517148 33c0         xor     eax,eax       ; eax = 0 = S_OK
7151714a e972010000  jmp     ReturnNoEBX (715172c1) ; return, do not pop EBX
```

The compiler delayed saving the EBX register until later in the function, so if the program is going to "early-out" on this test, then the exit path needs to be the one that does not restore EBX.

```
BOOL fViewObjectChanged = FALSE;
ReleaseAndNull(&m_pdtgt);
```

The execution of these two lines of code is interleaved, so pay attention.

```
NotDestroyed:
7151714f 8d86c0000000  lea     eax,[esi+0xc0]    ; eax = &m_pdtgt
```

The **lea** instruction computes the effect address of a memory access and stores it in the destination. The actual memory address is not dereferenced.

The lea instruction takes the address of a variable.

```
71517155 53          push    ebx
```

You should save that EBX register before it is damaged.

```
71517156 8b1d10195071  mov     ebx,[_imp__ReleaseAndNull]
```

Because you will be calling **ReleaseAndNull** frequently, it is a good idea to cache its address in EBX.

```
7151715c 50          push    eax           ; parameter to ReleaseAndNull
7151715d 897dfc      mov     [ebp-0x4],edi   ; fViewObjectChanged = FALSE
71517160 ffd3         call    ebx           ; call ReleaseAndNull
if (m_psv) {
71517162 397e74      cmp     [esi+0x74],edi    ; this->m_psv == 0?
71517165 0f841010000  je      No_Psv (7151727c) ; jump if zero
```

Remember that you zeroed out the EDI register a while back and that EDI is a register preserved across function calls (so the call to **ReleaseAndNull** did not change it). Therefore, it still holds the value zero and you can use it to quickly test for zero.

```
m_psb->EnableModelessSB(FALSE);
7151716b 8b4638      mov     eax,[esi+0x38]    ; eax = this->m_psb
7151716e 57          push    edi           ; FALSE
7151716f 50          push    eax           ; "this" for callee
71517170 8b08         mov     ecx,[eax]      ; ecx = m_psb->lpVtbl
71517172 ff5124      call    [ecx+0x24]    ; __stdcall EnableModelessSB
```

The above pattern is a telltale sign of a COM method call.

COM method calls are pretty popular, so it is a good idea to learn to recognize them. In particular, you should be able to recognize the three IUnknown methods directly from their Vtable offsets: QueryInterface=0, AddRef=4, and Release=8.

```
if(m_pws) m_pws->ViewReleased();
71517175 8b8614010000  mov     eax,[esi+0x114]    ; eax = this->m_pws
7151717b 3bc7         cmp     eax,edi        ; eax == 0?
7151717d 7406         jz      NOWS (71517185) ; if so, then jump
7151717f 8b08         mov     ecx,[eax]      ; ecx = m_pws->lpVtbl
71517181 50          push    eax           ; "this" for callee
71517182 ff510c      call    [ecx+0xc]    ; __stdcall ViewReleased
NowS:
```

```
HWND hwndCapture = GetCapture();
71517185 ff15e01a5071  call    [_imp__GetCapture]    ; call GetCapture
```

Indirect calls through globals is how function imports are implemented in Microsoft Win32. The loader fixes up the globals to point to the actual address of the target. This is a handy way to get your bearings when you are investigating a crashed machine. Look for the calls to imported functions and in the target. You will usually have the name of some imported function, which you can use to determine where you are in the source code.

```
if (hwndCapture && hwndCapture == m_hwnd) {
    SendMessage(m_hwnd, WM_CANCELMODE, 0, 0);
```

```

    }
7151718b 3bc7      cmp     eax,edi          ; hwndCapture == 0?
7151718d 7412      jz      No_Capture (715171a1) ; jump if zero

The function return value is placed in the EAX register.

7151718f 8b4e44      mov     ecx,[esi+0x44]   ; ecx = this->m_hwnd
71517192 3bc1      cmp     eax,ecx          ; hwndCapture == ecx?
71517194 750b      jnz      No_Capture (715171a1) ; jump if not

71517196 57      push    edi          ; 0
71517197 57      push    edi          ; 0
71517198 6a1f      push    0x1f          ; WM_CANCELMODE
7151719a 51      push    ecx          ; hwndCapture
7151719b ff1518195071  call    [_imp__SendMessageW] ; SendMessage
No_Capture:
    m_fHandsOff = TRUE;
    m_fRecurse = TRUE;
715171a1 66818e0c0100000180 or word ptr [esi+0x10c],0x8001 ; set both flags at once

    NotifyClients(m_psv, NOTIFY_CLOSING);
715171aa 8b4e20      mov     ecx,[esi+0x20]   ; ecx = (CNotifySource*)this.vtbl
715171ad 6a04      push    0x4          ; NOTIFY_CLOSING
715171af 8d4620      lea     eax,[esi+0x20]   ; eax = (CNotifySource*)this
715171b2 ff7674      push    [esi+0x74]    ; m_psv
715171b5 50      push    eax          ; "this" for callee
715171b6 ff510c      call    [ecx+0xc]    ; __stdcall NotifyClients

```

Notice how you had to change your "this" pointer when calling a method on a different base class from your own.

```

    m_fRecurse = FALSE;
715171b9 80a60d0100007f and byte ptr [esi+0x10d],0x7f
    m_psv->UIActivate(SVUIA_DEACTIVATE);
715171c0 8b4674      mov     eax,[esi+0x74]   ; eax = m_psv
715171c3 57      push    edi          ; SVUIA_DEACTIVATE = 0
715171c4 50      push    eax          ; "this" for callee
715171c5 8b08      mov     ecx,[eax]    ; ecx = vtbl
715171c7 ff511c      call    [ecx+0x1c]    ; __stdcall UIActivate
    psv = m_psv;
    m_psv = NULL;
715171ca 8b4674      mov     eax,[esi+0x74]   ; eax = m_psv
715171cd 897e74      mov     [esi+0x74],edi ; m_psv = NULL
715171d0 8945f8      mov     [ebp-0x8],eax ; psv = eax

```

The first local variable is psv.

```

    ReleaseAndNull(&_pctView);
715171d3 8d466c      lea     eax,[esi+0x6c]   ; eax = &_pctView
715171d6 50      push    eax          ; parameter
715171d7 ffd3      call    ebx          ; call ReleaseAndNull
    if (m_pvo) {
715171d9 8b86a8000000  mov     eax,[esi+0xa8]   ; eax = m_pvo
715171df 8dbea8000000  lea     edi,[esi+0xa8]   ; edi = &m_pvo
715171e5 85c0      test   eax,edx          ; eax == 0?
715171e7 7448      jz      No_Pvo (71517231) ; jump if zero

```

Note that the compiler speculatively prepared the address of the m_pvo member, because you are going to use it frequently for a while. Thus, having the address handy will result in smaller code.

```

    if (SUCCEEDED(m_pvo->GetAdvise(NULL, NULL, &pSink)) && pSink) {
715171e9 8b08      mov     ecx,[eax]    ; ecx = m_pvo->lpVtbl
715171eb 8d5508      lea     edx,[ebp+0x8]   ; edx = &pSink
715171ee 52      push    edx          ; parameter
715171ef 6a00      push    0x0          ; NULL
715171f1 6a00      push    0x0          ; NULL
715171f3 50      push    eax          ; "this" for callee
715171f4 ff5120      call    [ecx+0x20]    ; __stdcall GetAdvise
715171f7 85c0      test   eax,edx          ; test bits of eax
715171f9 7c2c      jl      No_Advise (71517227) ; jump if less than zero
715171fb 33c9      xor    ecx,ecx          ; ecx = 0
715171fd 394d08      cmp     [ebp+0x8],ecx ; pSink == ecx?
71517200 7425      jz      No_Advise (71517227)

```

Notice that the compiler concluded that the incoming "this" parameter was not required (because it long ago stashed that into the ESI register). Thus, it reused the memory as the local variable pSink.

If the function uses an EBP frame, then incoming parameters arrive at positive offsets from EBP and local variables are placed at negative offsets. But, as in this case, the compiler is free to reuse that memory for any purpose.

If you are paying close attention, you will see that the compiler could have optimized this code a little better. It could have delayed the `lea edi, [esi+0xa8]` instruction until after the two `push 0x0` instructions, replacing them with `push edi`. This would have saved 2 bytes.

```
if (pSink == (IAdviseSink *)this)
```

These next several lines are to compensate for the fact that in C++, `(IAdviseSink *)NULL` must still be `NULL`. So if your "this" is really `"(ViewState*)NULL"`, then the result of the cast should be `NULL` and not the distance between `IAdviseSink` and `IBrowserService`.

```

71517202 8d46ec      lea     eax,[esi-0x14]   ; eax = -(IAdviseSink*)this
71517205 8d5614      lea     edx,[esi+0x14]   ; edx = (IAdviseSink*)this
71517208 f7d8      neg    eax          ; eax = -eax (sets carry if != 0)
7151720a 1bc0      sbb    eax,eax        ; eax = eax - eax - carry

```

```
7151720c 23c2          and      eax,edx           ; eax = NULL or edx
```

Although the Pentium has a conditional move instruction, the base i386 architecture does not, so the compiler uses specific techniques to simulate a conditional move instruction without taking any jumps.

The general pattern for a conditional evaluation is the following:

```
neg    r
sbb    r, r
and   r, (val1 - val2)
add    r, val2
```

The **neg r** sets the carry flag if **r** is nonzero, because **neg** negates the value by subtracting from zero. And, subtracting from zero will generate a borrow (set the carry) if you subtract a nonzero value. It also damages the value in the **r** register, but that is acceptable because you are about to overwrite it anyway.

Next, the **sbb r, r** instruction subtracts a value from itself, which always results in zero. However, it also subtracts the carry (borrow) bit, so the net result is to set **r** to zero or -1, depending on whether the carry was clear or set, respectively.

Therefore, **sbb r, r** sets **r** to zero if the original value of **r** was zero, or to -1 if the original value was nonzero.

The third instruction performs a mask. Because the **r** register is zero or -1, "this" serves either to leave **r** zero or to change **r** from -1 to **(val1 - val1)**, in that ANDing any value with -1 leaves the original value.

Therefore, the result of "and r, (val1 - val1)" is to set **r** to zero if the original value of **r** was zero, or to "(val1 - val2)" if the original value of **r** was nonzero.

Finally, you add **val2** to **r**, resulting in **val2** or **(val1 - val2) + val2 = val1**.

Thus, the ultimate result of this series of instructions is to set **r** to **val2** if it was originally zero or to **val1** if it was nonzero. This is the assembly equivalent of **r = r ? val1 : val2**.

In this particular instance, you can see that **val2 = 0** and **val1 = (IAdviseSink*)this**. (Notice that the compiler elided the final **add eax, 0** instruction because it has no effect.)

```
7151720e 394508      cmp     [ebp+0x8],eax ; pSink == (IAdviseSink*)this?
71517211 750b        jnz    No_SetAdvise (7151721e) ; jump if not equal
```

Earlier in this section, you set EDI to the address of the **m_pvo** member. You are going to be using it now. You also zeroed out the ECX register earlier.

```
71517213 8b07        mov     eax,[edi]           ; eax = m_pvo
71517215 51          push    ecx               ; NULL
71517216 51          push    ecx               ; 0
71517217 51          push    ecx               ; 0
71517218 8b10        mov     edx,[eax]          ; edx = m_pvo->lpVtbl
7151721a 50          push    eax               ; "this" for callee
7151721b ff521c      call    [edx+0x1c]         ; __stdcall SetAdvise
No_SetAdvise:
    psink->Release();
7151721e 8b4508      mov     eax,[ebp+0x8]        ; eax = pSink
71517221 50          push    eax               ; "this" for callee
71517222 8b08        mov     ecx,[eax]          ; ecx = pSink->lpVtbl
71517224 ff5108      call    [ecx+0x8]          ; __stdcall Release
No_Advise:
```

All these COM method calls should look very familiar.

The evaluation of the next two statements is interleaved. Do not forget that EBX contains the address of **ReleaseAndNull**.

```
fViewObjectChanged = TRUE;
ReleaseAndNull(&m_pvo);
71517227 57          push    edi               ; &m_pvo
71517228 c745fc01000000  mov     dword ptr [ebp-0x4],0x1 ; fViewObjectChanged = TRUE
7151722f ffd3        call    ebx               ; call ReleaseAndNull
No_Pvo:
if (psv) {
71517231 8b7df8      mov     edi,[ebp-0x8]        ; edi = psv
71517234 85ff        test   edi,edi            ; edi == 0?
71517236 7412        jz    No_Psv2 (7151724a) ; jump if zero
    psv->SaveViewState();
71517238 8b07        mov     eax,[edi]          ; eax = psv->lpVtbl
7151723a 57          push    edi               ; "this" for callee
7151723b ff5034      call    [eax+0x34]         ; __stdcall SaveViewState
```

Here are more COM method calls.

```
psv->DestroyViewWindow();
7151723e 8b07        mov     eax,[edi]          ; eax = psv->lpVtbl
71517240 57          push    edi               ; "this" for callee
71517241 ff5028      call    [eax+0x28]         ; __stdcall DestroyViewWindow
    psv->Release();
71517244 8b07        mov     eax,[edi]          ; eax = psv->lpVtbl
71517246 57          push    edi               ; "this" for callee
71517247 ff5008      call    [eax+0x8]          ; __stdcall Release
No_Psv2:
    m_hwndView = NULL;
7151724a 83667c00    and    dword ptr [esi+0x7c],0x0 ; m_hwndView = 0
```

ANDing a memory location with zero is the same as setting it to zero, because anything AND zero is zero. The compiler uses this form because, even though it is slower, it is much shorter than the equivalent **mov** instruction. (This code was optimized for size, not speed.)

```

    m_fHandsOff = FALSE;
7151724e 83a60c010000fe    and     dword ptr [esi+0x10c],0xfe
    if (_m_pcache) {
71517255 8b4670          mov     eax,[esi+0x70] ; eax = _m_pcache
71517258 85c0            test    eax, eax ; eax == 0?
7151725a 740b            jz      No_Cache (71517267) ; jump if zero
        GlobalFree(_m_pcache);
7151725c 50              push    eax ; _m_pcache
7151725d ff15b4135071    call    [_imp__GlobalFree] ; call GlobalFree
        _m_pcache = NULL;
71517263 83667000    and     dword ptr [esi+0x70],0x0 ; _m_pcache = 0
No_Cache:
    m_psb->EnableModelessSB(TRUE);
71517267 8b4638          mov     eax,[esi+0x38] ; eax = this->m_psb
7151726a 6a01            push    0x1 ; TRUE
7151726c 50              push    eax ; "this" for callee
7151726d 8b08            mov     ecx,[eax] ; ecx = m_psb->lpVtbl
7151726f ff5124          call    [ecx+0x24] ; __stdcall EnableModelessSB
    CancelPendingActions();

```

In order to call **CancelPendingActions**, you have to move from (**ViewState***)this to (**CUserView***)this. Note also that **CancelPendingActions** uses the **_thiscall** calling convention instead of **_stdcall**. According to **_thiscall**, the "this" pointer is passed in the ECX register instead of being passed on the stack.

```

71517272 8d4eec          lea     ecx,[esi-0x14] ; ecx = (CUserView*)this
71517275 e832fbffff    call    CUserView::CancelPendingActions (71516dac) ; __thiscall
    ReleaseAndNull(&_psf);
7151727a 33ff            xor     edi,edi ; edi = 0 (for later)
No_Psv:
7151727c 8d4678          lea     eax,[esi+0x78] ; eax = &_psf
7151727f 50              push    eax ; parameter
71517280 ffd3            call    ebx ; call ReleaseAndNull
    if (fViewObjectChanged)
71517282 397dfc          cmp     [ebp-0x4],edi ; fViewObjectChanged == 0?
71517285 740d            jz      NoNotifyViewClients (71517294) ; jump if zero
        NotifyViewClients(DVASPECT_CONTENT,-1);
71517287 8b46ec          mov     eax,[esi-0x14] ; eax = ((CUserView*)this)->lpVtbl
7151728a 8d4eec          lea     ecx,[esi-0x14] ; ecx = (CUserView*)this
7151728d 6aff            push    0xff ; -1
7151728f 6a01            push    0x1 ; DVASPECT_CONTENT = 1
71517291 ff5024          call    [eax+0x24] ; __thiscall NotifyViewClients
NoNotifyViewClients:
    if (_pszTitle)
71517294 8b8680000000    mov     eax,[esi+0x80] ; eax = _m_pszTitle
7151729a 8d9e80000000    lea     ebx,[esi+0x80] ; ebx = &_m_pszTitle (for later)
715172a0 3bc7            cmp     eax,edi ; eax == 0?
715172a2 7409            jz      No_Title (715172ad) ; jump if zero
    LocalFree(_m_pszTitle);
715172a4 50              push    eax ; _m_pszTitle
715172a5 ff1538125071    call    [_imp__LocalFree]
    _m_pszTitle = NULL;

```

Remember that EDI is still zero and EBX is still **&m_pszTitle**, because those registers are preserved by function calls.

```

715172ab 893b            mov     [ebx],edi ; _m_pszTitle = 0
No_Title:
    SetRect(&_rcBounds, 0, 0, 0, 0);
715172ad 57              push    edi ; 0
715172ae 57              push    edi ; 0
715172af 57              push    edi ; 0
715172b0 81c6fc000000    add    esi,0xfc ; esi = &this->m_rcBounds
715172b6 57              push    edi ; 0
715172b7 56              push    esi ; &m_rcBounds
715172b8 ff15e41a5071    call    [_imp__SetRect]

```

Notice that you do not need the value of "this" any more, so the compiler uses the **add** instruction to modify it in place instead of using up another register to hold the address. This is actually a performance win due to the Pentium u/v pipelining, because the v pipe can do arithmetic, but not address computations.

```

    return S_OK;
715172be 33c0            xor     eax,eax ; eax = S_OK

```

Finally, you restore the registers you are required to preserve, clean up the stack, and return to your caller, removing the incoming parameters.

```

715172c0 5b              pop    ebx ; restore
ReturnNoEBX:
715172c1 5f              pop    edi ; restore
715172c2 5e              pop    esi ; restore
715172c3 c9              leave  ; restores EBP and ESP simultaneously
715172c4 c20400           ret    0x4 ; return and clear parameters

```

x64 Architecture

The x64 architecture is a backwards-compatible extension of x86. It provides a legacy 32-bit mode, which is identical to x86, and a new 64-bit mode.

The term "x64" includes both AMD 64 and Intel64. The instruction sets are close to identical.

Registers

x64 extends x86's 8 general-purpose registers to be 64-bit, and adds 8 new 64-bit registers. The 64-bit registers have names beginning with "r", so for example the 64-bit extension of **eax** is called **rax**. The new registers are named **r8** through **r15**.

The lower 32 bits, 16 bits, and 8 bits of each register are directly addressable in operands. This includes registers, like **esi**, whose lower 8 bits were not previously addressable. The following table specifies the assembly-language names for the lower portions of 64-bit registers.

64-bit register Lower 32 bits Lower 16 bits Lower 8 bits

rax	eax	ax	al
rbx	ebx	bx	bl
rcx	ecx	cx	cl
rdx	edx	dx	dl
rsi	esi	si	sil
rdi	edi	di	dil
rbp	ebp	bp	bp
rsp	esp	sp	sp
r8	r8d	r8w	r8b
r9	r9d	r9w	r9b
r10	r10d	r10w	r10b
r11	r11d	r11w	r11b
r12	r12d	r12w	r12b
r13	r13d	r13w	r13b
r14	r14d	r14w	r14b
r15	r15d	r15w	r15b

Operations that output to a 32-bit subregister are automatically zero-extended to the entire 64-bit register. Operations that output to 8-bit or 16-bit subregisters are *not* zero-extended (this is compatible x86 behavior).

The high 8 bits of **ax**, **bx**, , and **dx** are still addressable as **ah**, **bh**, **ch**, **dh**, but cannot be used with all types of operands.

The instruction pointer, **eip**, and **flags** register have been extended to 64 bits (**rip** and **rflags**, respectively) as well.

The x64 processor also provides several sets of floating-point registers:

- Eight 80-bit x87 registers.
- Eight 64-bit MMX registers. (These overlap with the x87 registers.)
- The original set of eight 128-bit SSE registers is increased to sixteen.

Calling Conventions

Unlike the x86, the C/C++ compiler only supports one calling convention on x64. This calling convention takes advantage of the increased number of registers available on x64:

- The first four integer or pointer parameters are passed in the **rcx**, **rdx**, **r8**, and **r9** registers.
- The first four floating-point parameters are passed in the first four SSE registers, **xmm0-xmm3**.
- The caller reserves space on the stack for arguments passed in registers. The called function can use this space to spill the contents of registers to the stack.
- Any additional arguments are passed on the stack.

- An integer or pointer return value is returned in the **rax** register, while a floating-point return value is returned in **xmm0**.
- **rax, rcx, rdx, r8-r11** are volatile.
- **rbx, rbp, rdi, rsi, r12-r15** are nonvolatile.

The calling convention for C++ is very similar: the **this** pointer is passed as an implicit first parameter. The next three parameters are passed in registers, while the rest are passed on the stack.

Addressing Modes

The addressing modes in 64-bit mode are similar to, but not identical to, x86.

- Instructions that refer to 64-bit registers are automatically performed with 64-bit precision. (For example **mov rax, [rbx]** moves 8 bytes beginning at **rbx** into **rax**.)
- A special form of the **mov** instruction has been added for 64-bit immediate constants or constant addresses. For all other instructions, immediate constants or constant addresses are still 32 bits.
- x64 provides a new **rip**-relative addressing mode. Instructions that refer to a single constant address are encoded as offsets from **rip**. For example, the **mov rax, [addr]** instruction moves 8 bytes beginning at **addr + rip** to **rax**.

Instructions, such as **jmp**, **call**, **push**, and **pop**, that implicitly refer to the instruction pointer and the stack pointer treat them as 64 bits registers on x64.

x64 Instructions

Most x86 instructions continue to be valid for x64 in 64-bit mode. Some rarely-used operations are no longer supported in 64-bit mode, such as:

- binary-coded decimal arithmetic instructions: AAA, AAD, AAM, AAS, DAA, DAS
- BOUND
- PUSHAD and POPAD
- most operations that dealt with segment registers, such as PUSH DS and POP DS. (Operations that use the FS or GS segment registers are still valid.)

The x64 instruction set includes recent additions to the x86, such as SSE 2. Programs compiled for x64 can freely use these instructions.

Data Transfer

The x64 provides new variants of the MOV instruction that can handle 64-bit immediate constants or memory addresses.

```
MOV r,#n    r = #n
MOV rax, m Move contents at 64-bit address to rax.
MOV m, rax Move contents of rax to 64-bit address.
```

The x64 also provides a new instruction to sign-extend 32-bit operands to 64 bits.

```
MOVSXD r1, r/m Move DWORD with sign extension to QWORD.
```

Ordinary MOV operations into 32-bit subregisters automatically zero extend to 64 bits, so there is no MOVZXD instruction.

Two SSE instructions can be used to move 128-bit values (such as GUIDs) from memory to an **xmmn** register or vice versa.

```
MOVDQA r1/m, r2/m Move 128-bit aligned value to xmmn register, or vice versa.
MOVDQU r1/m, r2/m Move 128-bit value (not necessarily aligned) to register, or vice versa.
```

Data Conversion

```
CDQE Convert dword (eax) to qword (rax).
CQO convert qword (rax) to oword (rdx:rax).
```

String Manipulation

MOVSQ Move qword from **rsi** to **rdi**.
 CMPSQ Compare qword at **rsi** with **rdi**.
 SCASQ Scan qword at **rdi**. Compares qword at **rdi** to **rax**.
 LODSQ Load qword from **rsi** into **rax**.
 STOSQ Store qword to **rdi** from **rax**.

Annotated x64 Disassembly

The following very simple function illustrates the x64 calling convention.

```
int Simple(int i, int j)
{
    return i*5 + j + 3;
}
```

This compiles to code like this:

```
01001080 lea     eax,[rdx+rcx*4]      ; eax = rdx+rcx*4
01001083 lea     eax,[rcx+rax+0x3]    ; eax = rcx+rax+3
01001087 ret
```

The *i* and *j* parameters are passed in the **ecx** and **edx** registers, respectively. Since there are only two parameters, the routine does not use the stack at all.

The particular code generated exploits three tricks, one of which is specific to the x64:

1. The **lea** operation can be used to perform a series of simple arithmetic operations as a single operation. The first instruction stores $j+i*4$ in **eax**, and the second instruction adds $i+3$ to the result, for a total of $j+i*5+3$.
2. Many operations, such as addition and multiplication, can be done with extra precision, and then truncated to the correct precision. In this instance, the code uses 64-bit addition and multiplication. We can safely truncate the result to 32 bits.
3. On the x64, any operation that outputs to a 32-bit register automatically zero-extends the result. In this case, outputting to **eax** has the effect of truncating the result to 32 bits.

Return values are passed in the **rax** register. In this case, the result is already in the **rax** register, so the function returns.

Next we consider a more complicated function to demonstrate typical x64 disassembly:

```
HRESULT Meaningless(IDispatch *pdisp, DISPID dispid, BOOL fUnique, LPCWSTR pszExe)
{
    IQueryAssociations *pqa;
    HRESULT hr = AssocCreate(CLSID_QueryAssociations, IID_IQueryAssociations, (void**)&pqa);
    if (SUCCEEDED(hr)) {
        hr = pqa->Init(ASSOCF_INIT_BYEXENAME, pszExe, NULL, NULL);
        if (SUCCEEDED(hr)) {
            WCHAR wszName[MAX_PATH];
            DWORD cchName = MAX_PATH;
            hr = pqa->GetString(0, ASSOCSTR_FRIENDLYAPPNAME, NULL, wszName, &cchName);
            if (SUCCEEDED(hr)) {
                VARIANTARG rgvarg[2] = { 0 };
                V_VT(&rgvarg[0]) = VT_BSTR;
                V_BSTR(&rgvarg[0]) = SysAllocString(wszName);
                if (V_BSTR(&rgvarg[0])) {
                    DISPPARAMS dp;
                    LONG lUnique = InterlockedIncrement(&lCounter);
                    V_VT(&rgvarg[1]) = VT_I4;
                    V_I4(&rgvarg[1]) = fUnique ? lUnique : 0;
                    dp.rgvarg = rgvarg;
                    dp.cArgs = 2;
                    dp.rgdispidNamedArgs = NULL;
                    dp.cNamedArgs = 0;
                    hr = pdisp->Invoke(dispid, IID_NULL, 0, DISPATCH_METHOD, &dp, NULL, NULL, NULL);
                    VariantClear(&rgvarg[0]);
                    VariantClear(&rgvarg[1]);
                } else {
                    hr = E_OUTOFMEMORY;
                }
            }
            pqa->Release();
        }
        return hr;
    }
}
```

We'll go through this function and the equivalent assembly line by line.

When entered, the function's parameters are stored as follows:

- **rcx** = *pdisp*.
- **rdx** = *dispid*.
- **r8** = *fUnique*.
- **r9** = *pszExe*.

Recall that the first four parameters are passed in registers. Since this function has only four registers, none are passed on the stack.

The assembly begins as follows:

```
Meaningless:
010010e0 push    rbx          ; save
010010e1 push    rsi          ; save
010010e2 push    rdi          ; save
010010e3 push    r12d         ; save
010010e5 push    r13d         ; save
010010e7 push    r14d         ; save
010010e9 push    r15d         ; save
010010eb sub     rsp,0x2c0   ; reserve stack
010010f2 mov     rbx,r9      ; rbx = pszExe
010010f5 mov     r12d,r8d    ; r12 = fUnique (zero-extend)
010010f8 mov     r13d,edx    ; r13 = dispid (zero-extend)
010010fb mov     rsi,rcx    ; rsi = pdisp
```

The function begins by saving nonvolatile registers, and then reserving stack space for local variables. It then saves parameters in nonvolatile registers. Note that the destination of the middle two **mov** instructions is a 32-bit register, so they are implicitly zero-extended to 64 bits.

```
IQueryAssociations *pqa;
HRESULT hr = AssocCreate(CLSID_QueryAssociations, IID_IQueryAssociations, (void**)&pqa);
```

The first parameter to **AssocCreate** is a 128-bit CLSID passed by value. Since this doesn't fit in a 64-bit register, the CLSID is copied to the stack, and a pointer to the stack location is passed instead.

```
010010fe movdqu  xmm0, oword ptr [CLSID_QueryAssociations (01001060)]
01001106 movdqu  oword ptr [rsp+0x60],xmm0 ; temp buffer for first parameter
0100110c lea     r8,[rsp+0x58]           ; arg3 = &pqa
01001111 lea     rdx,[IID_IQueryAssociations (01001070)] ; arg2 = &IID_IQueryAssociations
01001118 lea     rcx,[rsp+0x60]           ; arg1 = &temporary
0100111d call    qword ptr [_imp__AssocCreate (01001028)] ; call
```

The **movdqu** instruction transfers 128-bit values to and from **xmmn** registers. In this instance, the assembly code uses it to copy the CLSID to the stack. The pointer to the CLSID is passed in **r8**. The other two arguments are passed in **rcx** and **rdx**.

```
if (SUCCEEDED(hr)) {
01001123 test    eax,eax
01001125 jl     ReturnEAX (01001281)
```

The code checks to see if the return value is a success.

```
hr = pqa->Init(ASSOCF_INIT_BYEXENAME, pszExe, NULL, NULL);

0100112b mov     rcx,[rsp+0x58]           ; arg1 = pqa
01001130 mov     rax,[rcx]                ; rax = pqa.vtbl
01001133 xor     r14d,r14d              ; r14 = 0
01001136 mov     [rsp+0x20],r14           ; arg5 = 0
0100113b xor     r9d,r9d                ; arg4 = 0
0100113e mov     r8,rbx                 ; arg3 = pszExe
01001141 mov     r15d,0x2                ; r15 = 2 (for later)
01001147 mov     edx,r15d                ; arg2 = 2 (ASSOCF_INIT_BY_EXENAME)
0100114a call    qword ptr [rax+0x18]       ; call Init method
```

This is an indirect function call using a C++ vtable. The **this** pointer is passed in **rcx** as the first parameter. The first three parameters are passed in registers, while the final parameter is passed on the stack. The function reserves 16 bytes for the parameters passed in registers, so the fifth parameter begins at **rsp+0x20**.

```
if (SUCCEEDED(hr)) {
0100114d mov     ebx,eax                ; ebx = hr
0100114f test    ebx,ebx                ; FAILED?
01001151 jl     ReleasePQA (01001274) ; jump if so
```

The assembly-language code saves the result in **ebx**, and checks to see if it's a success code.

```
WCHAR wszName[MAX_PATH];
DWORD cchName = MAX_PATH;
hr = pqa->GetString(0, ASSOCSTR_FRIENDLYAPPNAME, NULL, wszName, &cchName);
if (SUCCEEDED(hr)) {

01001157 mov     dword ptr [rsp+0x50],0x104 ; cchName = MAX_PATH
0100115f mov     rcx,[rsp+0x58]           ; arg1 = pqa
01001164 mov     rax,[rcx]                ; rax = pqa.vtbl
01001167 lea     rdx,[rsp+0x50]           ; rdx = &cchName
0100116c mov     [rsp+0x28],rdx           ; arg6 = cchName
01001171 lea     rdx,[rsp+0xb0]           ; rdx = &wszName[0]
01001179 mov     [rsp+0x20],rdx           ; arg5 = &wszName[0]
0100117e xor     r9d,r9d                ; arg4 = 0
01001181 mov     r8d,0x4                ; arg3 = 4 (ASSOCSTR_FRIENDLYNAME)
01001187 xor     edx,edx                ; arg2 = 0
01001189 call    qword ptr [rax+0x20]       ; call GetString method
0100118c mov     ebx,eax                ; ebx = hr
0100118e test    ebx,ebx                ; FAILED?
```

```
01001190 jl      ReleasePQA (01001274) ; jump if so
```

Once again, we set up the parameters and call a function, then test the return value for success.

```
VARIANTARG rgvarg[2] = { 0 };

01001196 lea     rdi,[rsp+0x82]        ; rdi = &rgvarg
0100119e xor    eax,eax            ; eax = 0
010011a0 mov     ecx,0x2e          ; rcx = sizeof(rgvarg)
010011a5 rep     stosb             ; Zero it out
```

The idiomatic method for zeroing out a buffer on x64 is the same as x86.

```
V_VT(&rgvarg[0]) = VT_BSTR;
V_BSTR(&rgvarg[0]) = SysAllocString(wszName);
if (V_BSTR(rgvarg[0])) {

010011a7 mov     word ptr [rsp+0x80],0x8 ; V_VT(&rgvarg[0]) = VT_BSTR
010011b1 lea     rcx,[rsp+0xb0]        ; arg1 = &wszName[0]
010011b9 call    qword ptr _imp_SysAllocString (01001010) ; call
010011bf mov     [rsp+0x88],rax       ; V_BSTR(&rgvarg[0]) = result
010011c7 test   rax,rax            ; anything allocated?
010011ca je     OutOfMemory (0100126f) ; jump if failed

DISPPARAMS dp;
LONG lUnique = InterlockedIncrement(&lCounter);

010011d0 lea     rax,[lCounter (01002000)]
010011d7 mov     ecx,0x1           ; interlocked exchange and add
010011dc lock   xadd [rax],ecx
010011e0 add     ecx,0x1
```

InterlockedIncrement compiles directly to machine code. The **lock xadd** instruction performs an atomic exchange and add. The final result is stored in **ecx**.

```
V_VT(&rgvarg[1]) = VT_I4;
V_I4(&rgvarg[1]) = fUnique ? lUnique : 0;

010011e3 mov     word ptr [rsp+0x98],0x3    ; V_VT(&rgvarg[1]) = VT_I4;
010011ed mov     eax,r14d            ; rax = 0 (r14d is still zero)
010011f0 test   r12d,r12d          ; fUnique set?
010011f3 cmovne eax,ecx          ; if so, then set rax=lCounter
010011f6 mov     [rsp+0xa0],eax       ; V_I4(&rgvarg[1]) = ...
```

Since x64 supports the **cmove** instruction, the **?:** construct can be compiled without using a jump.

```
dp.rgvarg = rgvarg;
dp.cArgs = 2;
dp.rgdispidNamedArgs = NULL;
dp.cNamedArgs = 0;

010011fd lea     rax,[rsp+0x80]        ; rax = &rgvarg[0]
01001205 mov     [rsp+0x60],rax       ; dp.rgvarg = rgvarg
0100120a mov     [rsp+0x70],r15d        ; dp.cArgs = 2 (r15 is still 2)
0100120f mov     [rsp+0x68],r14        ; dp.rgdispidNamedArgs = NULL
01001214 mov     [rsp+0x74],r14d        ; dp.cNamedArgs = 0
```

This code initializes the rest of the members of DISPPARAMS. Note that the compiler reuses the space on the stack previously used by the CLSID.

```
hr = pdisp->Invoke(dispid, IID_NULL, 0, DISPATCH_METHOD, &dp, NULL, NULL, NULL);

01001219 mov     rax,[rsi]           ; rax = pdisp.vtbl
0100121c mov     [rsp+0x40],r14        ; arg9 = 0
01001221 mov     [rsp+0x38],r14        ; arg8 = 0
01001226 mov     [rsp+0x30],r14        ; arg7 = 0
0100122b lea     rcx,[rsp+0x60]        ; rcx = &dp
01001230 mov     [rsp+0x28],rcx        ; arg6 = &dp
01001235 mov     word ptr [rsp+0x20],0x1  ; arg5 = 1 (DISPATCH_METHOD)
0100123c xor     r9d,r9d            ; arg4 = 0
0100123f lea     r8,[GUID_NULL (01001080)] ; arg3 = &IID_NULL
01001246 mov     edx,r13d            ; arg2 = dispid
01001249 mov     rcx,rsi            ; arg1 = pdisp
0100124c call    qword ptr [rax+0x30]    ; call Invoke method
0100124f mov     ebx,eax            ; hr = result
```

The code then sets up the parameters and calls the **Invoke** method.

```
VariantClear(&rgvarg[0]);
VariantClear(&rgvarg[1]);

01001251 lea     rcx,[rsp+0x80]        ; arg1 = &rgvarg[0]
01001259 call    qword ptr _imp_VariantClear (01001018)
0100125f lea     rcx,[rsp+0x98]        ; arg1 = &rgvarg[1]
01001267 call    qword ptr _imp_VariantClear (01001018)
0100126d jmp     ReleasePQA (01001274)
```

The code finishes up the current branch of the conditional, and skips over the **else** branch.

```
} else {
    hr = E_OUTOFMEMORY;
}

OutOfMemory:
0100126f mov     ebx,0x8007000e        ; hr = E_OUTOFMEMORY
    pga->Release();
ReleasePQA:
```

```
01001274 mov    rcx,[rsp+0x58]          ; arg1 = pqa
01001279 mov    rax,[rcx]              ; rax = pqa.vtbl
0100127c call   qword ptr [rax+0x10]      ; release
```

The **else** branch.

```
    return hr;
}

0100127f mov    eax,ebx               ; rax = hr (for return value)
ReturnEAX:
01001281 add    rsp,0x2c0             ; clean up the stack
01001288 pop   r15d                ; restore
0100128a pop   r14d                ; restore
0100128c pop   r13d                ; restore
0100128e pop   r12d                ; restore
01001290 pop   rdi                 ; restore
01001291 pop   rsi                 ; restore
01001292 pop   rbx                 ; restore
01001293 ret                  ; return (do not pop arguments)

Debugger Engine and Extension APIs

This section includes:

[Debugger Engine Overview](#)

[Using the Debugger Engine API](#)

[Writing DbgEng Extensions](#)

[EngExtCpp Extensions](#)

[Writing WdbgExts Extensions](#)

[Customizing Debugger Output Using DML](#)

[Using JavaScript to Extend the Capabilities of the Debugger](#)

This documentation describes how to use the debugger engine and how to write extensions that will run in WinDbg, KD, CDB, and NTSD. These debugger extensions can be used when performing user-mode or kernel-mode debugging on Microsoft Windows.

Debugger Engine

The debugger engine provides an interface for examining and manipulating debugging targets in user-mode and kernel-mode on Microsoft Windows.

The debugger engine can acquire targets, set breakpoints, monitor events, query symbols, read and write memory, and control threads and processes in a target.

You can use the debugger engine to write both debugger extension libraries and stand-alone applications. Such applications are *debugger engine applications*. A debugger engine application that uses the full functionality of the debugger engine is a *debugger*. For example, WinDbg, CDB, NTSD, and KD are debuggers; the debugger engine provides the core of their functionality.

The debugger engine API is specified by the prototypes in the header file dbgeng.h.

For more information, see [Debugger Engine Overview](#) and [Using the Debugger Engine API](#).

Extensions

You can create your own debugging commands by writing and building an extension DLL. For example, you might want to write an extension command to display a complex data structure.

There are three different types of debugger extension DLLs:

- *DbgEng extension DLLs*. These are based on the prototypes in the dbgeng.h header file. Each DLL of this type may export DbgEng extension commands. These extension commands use the Debugger Engine API and may also use the WdbgExts API.

For more information, see [Writing DbgEng Extensions](#).

- *EngExtCpp extension DLLs*. These are based on the prototypes in the engextcpp.h and dbgeng.h header files. Each DLL of this type may export DbgEng extension commands. These extension commands use both the Debugger Engine API and the EngExtCpp extension framework, and may also use the WdbgExts API.

- *WdbgExts extension DLLs*. These are based on the prototypes in the wdbgexsts.h header file. Each DLL of this type exports one or more WdbgExts extension commands. These extension commands use the WdbgExts API exclusively. For more information see [Writing WdbgExts Extensions](#).

The DbgEng API can be used to create extensions or stand-alone applications. The WdbgExts API contains a subset of the functionality of the debugger engine API and can be used only by extensions.

All debugger extensions should be compiled and built by using the Build utility. The Build utility is included in the Windows Driver Kit (WDK).

Extension code samples are installed as part of the Debugging Tools for Windows package if you perform a custom installation and select the **SDK** component and all its subcomponents. They can be found in the sdk\samples subdirectory of the Debugging Tools for Windows installation directory.

The easiest way to write new debugger extensions is to study the sample extensions. Each sample extension includes makefile and sources files for use with the Build utility. Both types of extensions are represented in the samples.

Writing Custom Analysis Debugger Extensions

You can extend the capabilities of the [!analyze](#) debugger command by writing an analysis extension plugin. By providing an analysis extension plugin, you can participate in the analysis of a bug check or an exception in a way that is specific to your own component or application. When you write an analysis extension plugin, you also write a metadata file that describes the situations for which you want your plugin to be called. When [!analyze](#) runs, it locates, loads, and runs the appropriate analysis extension plugins. For more information, see [Writing Custom Analysis Debugger Extensions](#).

Customizing Debugger Output Using DML

You can customize debugger output using DML. For more information see [Customizing Debugger Output Using DML](#).

Using JavaScript to Extend the Capabilities of the Debugger

Use JavaScript to create scripts that understand debugger objects and extend and customize the capabilities of the debugger. JavaScript providers bridge a scripting language to the debugger's internal object model. The JavaScript debugger scripting provider, allows the use of JavaScript with the debugger. For more information, see [JavaScript Debugger Scripting](#).

Debugger Engine Overview

The *debugger engine* (DbgEng.dll), typically referred to as the *engine*, provides an interface for examining and manipulating debugging targets in *user mode* and *kernel mode* on Microsoft Windows.

The debugger engine can acquire targets, set [breakpoints](#), monitor [events](#), query [symbols](#), read and write to memory, and control [threads](#) and [processes](#) in a target.

You can use the debugger engine to write both debugger extension libraries and stand-alone applications. Such applications are referred to as *debugger engine applications*. A debugger engine application that uses the full functionality of the debugger engine is called a *debugger*. For example, WinDbg, CDB, NTSD, and KD are debuggers; the debugger engine provides the core of their functionality.

Engine Concepts:

[Debugging Session and Execution Model](#)

[Client Objects](#)

[Input and Output](#)

Examining and Manipulating Targets:

Debugging Session and Execution Model

The debugger engine can debug multiple targets, simultaneously. A *debugging session* begins when the engine acquires a target and continues until all of the targets have been discarded. A debugging session is *inaccessible* while the targets are executing and *accessible* when the current target is suspended. The engine can only be used to examine and manipulate targets while the session is accessible.

The main loop of a debugger typically consists of setting the execution status, calling the method [WaitForEvent](#) and handling the generated [events](#). When [WaitForEvent](#) is called, the session becomes inaccessible.

When an event occurs in a target, the engine suspends all targets and the session becomes accessible. The engine then notifies the event callbacks of the event and follows the event filter rules. The event callbacks and event filters determine how execution in the target should proceed. If they determine that the engine should break into the debugger, the [WaitForEvent](#) method returns and the session remains accessible; otherwise, the engine will resume execution of the target in the manner determined by the event callbacks and event filters, and the session becomes inaccessible again.

For the duration of the [WaitForEvent](#) call--in particular, while notifying the event callbacks and processing the filter rules--the engine is in a state referred to as "inside a wait". While in this state, [WaitForEvent](#) cannot be called (it is not reentrant).

There are two steps involved in initiating execution in a target: setting the execution status, and then calling [WaitForEvent](#). The execution status can be set using the method [SetExecutionStatus](#) or by executing a debugger command that sets the execution status--for example, [g\(Go\)](#) and [p\(Step\)](#).

If a sequence of debugger commands are executed together--for example, "[g ; ? @\\$ip](#)"--an *implicit wait* will occur after any command that requires execution in the target if that command is not the last command in the sequence. An implicit wait cannot occur when the debugger engine is in the state "inside a wait"; in this case, the execution of the commands will stop and the current command--the one that attempted to cause the implicit wait--will be interpreted as an indication of how execution in the target should proceed. The rest of the commands will be discarded.

Note When determining whether the session is accessible or inaccessible, limited execution of a target (for example, stepping) is considered execution by the engine. When the limited execution is complete, the session becomes accessible.

Host Engine

When debugging remotely, you can use multiple instances of the debugger engine. Exactly one of these instances maintains the debugging session; this instance is called the *host engine*.

All debugger operations are relative to the host engine, for example, symbol loading and extension loading.

Client Objects

Almost all interaction with the [debugger engine](#) is through *client objects*, often simply referred to as *clients*. Each client provides an implementation of the top-level engine interfaces. Each interface provides a different set of methods, which can be used to interact with the engine and, through the engine, the targets. An instance of the engine can have many clients, each with its own state.

Primary Clients

A *primary client* is a client that has joined the current debugging session. Initially, when a new client object is created, it is not a primary client. A client becomes a primary client when it is used to acquire a target (for example, by calling [CreateProcess2](#)) or is connected to the debugging session using [ConnectSession](#). The debugger command [clients](#) lists only the primary clients.

Callback Objects

Callback objects can be registered with each client. There are three types of callback objects:

1. **Input Callback Objects** (or *input callbacks*): the engine calls input callbacks to request input. For example, a debugger with a console window could register an input callback to provide the engine with input from the user, or a debugger might register an input callback to provide the engine with input from a file.
2. **Output Callback Objects** (or *output callbacks*): the engine calls output callbacks to display output. For example, a debugger with a console window could register an output callback to present the debugger's output to the user, or a debugger might register an output callback to send the output to a log file.
3. **Event Callback Objects** (or *event callbacks*): the engine calls event callbacks whenever an event occurs in a target (or there is a change in the engine's state). For example, a debugger extension library could register an event callback to monitor certain events or perform automated actions when a particular event occurs.

Remote Debugging

Client objects facilitate communication to remote instances of the host engine. The [DebugConnect](#) function creates a client object that is connected to a remote engine instance; methods called on this client are executed by the remote engine and callback objects registered locally with the client will be called when the remote engine makes callback calls.

Additional Information

For details about creating and using client objects, see [Using Client Objects](#). For details about registering callback objects, see [Using Callback Objects](#).

Input and Output

The input and output facilities of the [debugger engine](#) can be used for interactive debugger operation and logging. The input usually represents commands and responses that are typed by the user, and the output usually represents information presented to the user or sent to log files.

The debugger engine maintains an *input stream* and an *output stream*. Input can be requested from the input stream, and output sent to the output stream.

When the [Input](#) method is called to request input from the engine's input stream, the engine will call all the registered [input callbacks](#) to inform them that it is waiting for input. It then waits for the input callbacks to provide the input by calling the [ReturnInput](#) method.

When output is sent to the engine's output stream, the engine will call the registered [output callbacks](#) passing the output to them. When sending output to the output stream, it can be filtered by the client object; in which case, only output callbacks that are registered with particular client objects will receive the output.

The input and output streams are transparently available to the remote clients. Remote clients can request input and send output to the engine's input and output stream, and the engine will call the callbacks registered with remote clients to request input or send output.

Additional Information

For details about using input and output, see [Using Input and Output](#). For more information about client objects and input and output callbacks, see [Client Objects](#).

Remote Debugging

Remote debugging occurs when a client's communication with a target is indirect, for example, through a network connection. When remote debugging, more than one instance of the debugger engine can be involved in debugging a target. However, exactly one of these instances is responsible for the debugging session; this instance is called the *host engine*.

There are many possible configurations: the client object can be created in the host engine (smart clients), or a different instance of the engine (debugging clients); the host engine can be connected directly to the target (debugging server); or a proxy can be directly connected to the target (process server and kernel connection server).

Multiple clients can simultaneously connect to the host engine. And the host engine can connect to multiple targets in the same debugging session. Optionally, there can be one or more proxies between the clients and the host engine and between the host engine and each target.

Smart clients are client objects that communicate directly with the host engine. A debugging client is created by calling [DebugConnect](#); the client communicates with the host engine using RPC calls that represent method calls in the engine's API (including calls that the host engine makes to the client's [callback objects](#)).

A debugging server is an engine instance that communicates directly with the target and is also the host engine. Process servers and kernel connection servers communicate directly with the target but are not the host engine. The host engine communicates with the process server, or kernel connection server, by sending low-level memory, processor, and operating system requests, and the server sends back the results.

Note A typical two-computer setup for kernel debugging--where one computer is the target and the other the host computer--is not considered to be remote debugging as there is only one instance of the engine (on the host computer) and it communicates directly with the target.

Additional Information

For details about performing remote debugging, see [Remote Targets](#).

[Send comments about this topic to Microsoft](#)

Targets

The [debugger engine](#) supports debugging different types of targets, [user-mode](#) and [kernel-mode](#) targets, live targets and crash dump files, and local and remote targets. There are different methods for connecting the engine to these different types of targets.

Crash Dump Files

Both user-mode, and kernel-mode crash-dump files are opened with [OpenDumpFile](#). The engine is also able to create dump files from a target with [WriteDumpFile2](#).

Live, User-Mode Targets

The debugger engine can both create and attach to user-mode processes.

Creating a process is done by providing a command line, and optionally an initial directory and environment, for the new process. The engine can then connect to the new process, or keep the new process suspended while it connects to another process. For example, when debugging an application that consists of both a client and server, it is possible to create a client in a suspended state and attach to an already running server, allowing server breakpoints to be set before the client runs and provokes server operations.

When detaching from a process, the engine can optionally leave the process running normally, kill the process, or abandon the process (leaving it suspended until another debugger attaches to it or it is killed).

The engine can be queried for information about all of the user-mode processes that are running on the computer, including the process ID and name of the executable image that is used to start the process. This information can be used to help locate a process to debug.

Live, Kernel-Mode Targets

The method [AttachKernel](#) connects the debugger engine to a Windows kernel.

Remote Targets

When using the debugger engine to debug remotely, there are potentially two extra steps:

1. Connect to the host engine. If the host engine is not the local engine instance, use [DebugConnect](#) to create a client object that is connected to the host engine.
2. Connect the host engine to the process server or kernel connection server. If the host engine does not connect directly to the target, it must connect to a process server or kernel connection server that does.

Now the client can tell the host engine to acquire a target through the process server or kernel connection server.

Acquiring Targets

When acquiring a target, the acquisition of the target is not complete until the target generates an event. Typically, this means first calling a method to attach the debugger to the target, then calling [WaitForEvent](#) to let the target generate an event. This still holds true when the target is a crash dump file, as these always store an event—typically the event that caused the dump file to be created.

Additional Information

For details about attaching to targets, see [Connecting to Targets](#).

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

Events

The debugger engine provides facilities for monitoring and responding to events in the target. When an event occurs, the engine suspends the target (often only briefly), it then notifies all of the clients of the event, who in turn instruct the engine on how execution should proceed in the target.

To notify a client of an event, the engine calls the event callback object that is registered with the client. The engine provides each event callback with details of the event, and the event callback instructs the engine on how execution should proceed in the target. When different event callbacks provide conflicting instructions, the engine acts on the instruction with the highest precedence (see [DEBUG_STATUS_XXX](#)), which typically means choosing the instruction that involves the least execution of the target.

Note While the event callback is handling the event, the target is suspended and the debugging session is accessible; however, because the engine was waiting for an event—either explicitly during a [WaitForEvent](#) call or implicitly by executing a command such as [g \(Go\)](#) or [p \(Step\)](#)—the event callback cannot call [WaitForEvent](#), and if it attempts to execute any commands that would cause the debugger to execute, for example [g \(Go\)](#) or [p \(Step\)](#), the engine will interpret these commands as an instruction on how to proceed.

Event Filters

The debugger engine also provides *event filters*, which are a simpler alternative for basic event monitoring. The event filters provide a few simple rules that specify whether an event should be printed to the debugger's output stream or break into the debugger. They can also be used to execute debugger commands when an event occurs.

Additional Information

For details about monitoring events, see [Monitoring Events](#).

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

Breakpoints

The [debugger engine](#) can create and monitor breakpoints in the target.

There are two types of breakpoints that the engine can insert into a target: software breakpoints and processor breakpoints.

- *Software breakpoints* are inserted into the target's code by modifying the processor instruction at the breakpoint's location. The debugger engine keeps track of such breakpoints; they are invisible to the clients reading and writing memory at that location. A software breakpoint is triggered when the target executes the modified instruction.
- *Processor breakpoints* are inserted into the target's processor by the debugger engine. A processor breakpoint can be triggered by different actions, for example, executing an instruction at the location (like software breakpoints), or reading or writing memory at the breakpoint's location. Support for processor breakpoints is dependent on the processor in the target's computer.

A breakpoint's address can be specified by an explicit address, by an expression that evaluates to an address, or by an expression that might evaluate to an address at a future time. In the last case, each time a module is loaded or unloaded in the target, the engine will attempt to reevaluate the expression and insert the breakpoint if it can determine the address; this makes it possible to set breakpoints in modules before they are loaded.

A number of parameters can be associated with a breakpoint to control its behavior:

- A breakpoint can be associated with a particular thread in the target and will only be triggered by that thread.
- A breakpoint can have debugger commands associated with it; these commands will automatically be executed when the breakpoint is triggered.
- A breakpoint can be flagged as inactive until the target has passed it a specified number of times.
- A breakpoint can be automatically removed the first time it is triggered.

Additional Information

For details about using breakpoints, see [Using Breakpoints](#).

[Send comments about this topic to Microsoft](#)

Symbols

A *symbol* is a named unit of data or code from a source file that appears in a module. Information about symbols can include the name, type (if applicable), the address or register where it is stored, and any parent or child symbols. Examples of symbols include variables (local and global), functions, and any entry point into a module.

The symbol information is used by the engine to help interpret data and code in the target. With this information, the engine can search for symbols by name or location in memory and provide a description of a symbol.

The engine gets its information about symbols from symbol files, which are located on the local file system or loaded from a symbol server. When using a symbol server, the engine will automatically use the correct version of the symbol file to match the module in the target. Symbol files can be loaded whenever the corresponding module is loaded, or they can be loaded as needed.

Note Often optimizing compilers do not include accurate information in symbol files. This can cause the engine to misinterpret the value of some variables as the variable's location or lifetime might be incorrectly described, causing the engine to look at the wrong piece of memory or think a variable value is live when it is dead (or vice versa). It is also possible for an optimizing compiler to change the order of execution or to split a function into several pieces. Best results are usually obtained when debugging unoptimized code.

Additional Information

For details about using symbols, see [Using Symbols](#). For an overview of using symbol files and symbol servers, see [Symbols](#) in the Debuggers section of this documentation.

Memory

The [debugger engine](#) can directly read and write the target's main memory, registers, and other data spaces. In kernel-mode debugging, all of the target's memory is available, including virtual memory, physical memory, registers, Model Specific Registers (MSRs), System Bus Memory, Control-Space Memory, and I/O Memory. In user-mode debugging, only the virtual memory and registers are available.

The engine exposes, to the clients, all memory in the target using 64-bit addresses. If the target uses 32-bit addresses, when communicating with the target and the clients, the engine will automatically convert between 32-bit and 64-bit addresses, as needed. If a 32-bit address is recovered from the target—for example, by reading from memory or a register—it must be sign-extended to 64 bits before it can be used in the debugger engine API. Sign extension is performed automatically by the [ReadPointersVirtual](#) method.

Additional Information

For details about reading and writing memory, see [Memory Access](#).

Threads and Processes

Terminology

Thread and a process concepts are different between user-mode debugging and kernel-mode debugging.

- In *user-mode debugging*, a *process* is an operating system process and a *thread* is an operating system thread.
- In *kernel-mode debugging*, the [debugger engine](#) creates a *virtual process* for each target; this process represents the kernel and does not correspond to any operating system process. For each physical processor in the target computer, the debugger creates a *virtual thread*; these threads represent the processors and do not correspond to any operating system threads.

When an event occurs, the engine sets the *event process* and *event thread* to the process and thread (operating system or virtual) in which the event occurred.

The *current thread* is the thread (operating system or virtual) that the engine is currently controlling. The *current process* is the process (operating system or virtual) that the engine is currently controlling. When an event occurs, the current thread and process are initially set to the event thread and process; but, they can be changed using the clients while the session is accessible.

In kernel mode, the debugger keeps track of an implicit process and implicit thread. The *implicit process* is the operating system process that determines the translation from virtual to physical memory addresses.

The *implicit thread* is the operating system thread that determines the target's registers, including call stack, stack frame, and instruction offset.

When an event occurs, the implicit thread and implicit process are initially set to the event thread and process; they can be changed while the session is accessible.

Thread and Process Data

The engine maintains several pieces of information about each thread and process. This includes the system thread and process ID and system handles, and the process environment (PEB), the thread environment block (TEB), and their locations in target's memory.

Additional Information

For details about using thread and processes, see [Controlling Threads and Processes](#).

Interacting with the Engine

Commands and Expressions

The debugger engine API provides methods to execute commands and evaluate expressions, like those typed into WinDbg's [Debugger Command Window](#). To execute a debugger command, use [Execute](#). Or, to execute all of the commands in a file, use [ExecuteCommandFile](#).

The method [Evaluate](#) will evaluate expressions using the C++ or MASM syntax. The syntax used by the debugger engine to evaluate expressions--such as in the [Evaluate](#) method--is given by [GetExpressionSyntax](#) and can be changed using [SetExpressionSyntaxByName](#) and [SetExpressionSyntax](#). The number of different syntaxes that are recognized by the debugger is returned by [GetNumberExpressionSyntaxes](#), and their names are returned by [GetExpressionSyntaxNames](#).

The type of value that is returned by [Evaluate](#) is determined by the symbols and constants used in the string that was evaluated. The value is contained in a [DEBUG_VALUE](#) structure and can be cast to different types using [CoerceValue](#) and [CoerceValues](#).

Aliases

Aliases are character strings that are automatically replaced with other character strings when used in debugger commands and expressions. For an overview of aliases, see [Using Aliases](#). The debugger engine has several classes of aliases.

The *fixed-name aliases* are indexed by number and have the names **\$u0**, **\$u1**, ..., **\$u9**. The values of these aliases can be set using the [SetTextMacro](#) method and can be retrieved using [GetTextMacro](#) method.

The *automatic aliases* and *user-named aliases* can have any name. The automatic aliases are defined by the debugger engine and the user-named aliases are defined by the user through debugger commands or the debugger engine API. To define or remove a user-named alias, use the [SetTextReplacement](#) method. The [GetTextReplacement](#) method returns the name and value of an automatic alias or a user-named alias. All the user-named aliases can be removed using the [RemoveTextReplacements](#) method. The [GetNumberTextReplacements](#) method will return the number of user-name and automatic aliases; this can be used with [GetTextReplacement](#) to iterate over all these aliases. The [OutputTextReplacements](#) method will print a list of all the user-named aliases, including their names and values.

Note if a user-named alias is given the same name as an automatic alias, the user-named alias will hide the automatic alias so that when retrieving the value of the alias by name, the user-named alias will be used.

Engine Options

The engine has a number of options that control its behavior. These options are listed in [DEBUG_ENGOPT_XXX](#). They are returned by [GetEngineOptions](#) and can be set using [SetEngineOptions](#). Individual options can be set using [AddEngineOptions](#) and unset using [RemoveEngineOptions](#).

Interrupts

An interrupt is a way to force a break into the debugger or to tell the engine to stop processing the current command, for example, by pressing Ctrl+Break in WinDbg.

To request a break into the debugger, or to interrupt the debugger's current task, use [SetInterrupt](#). To check if there has been an interrupt, use [GetInterrupt](#).

Note When undertaking a long task from a debugger extension, it is recommended that the extension check [GetInterrupt](#) regularly and stop processing if an interrupt has been requested.

When requesting a break into the debugger, the engine might time out if it takes too long for the target to carry out the break-in. This can occur if the target is in a non-responsive state or if the break-in request is blocked or delayed by resource contention. The length of time the engine will wait is returned by [GetInterruptTimeout](#) and can be set using [SetInterruptTimeout](#).

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

Using Client Objects

For an overview of the role of client objects in interacting with the debugger engine, see [Client Objects](#).

In general, a client's methods may be called only from the thread in which the client was created. Typically, methods called from the wrong thread will fail immediately. The notable exception to this rule is the method [CreateClient](#); this method may be called from any thread, and returns a new client that can be used in the thread from which it was called. Other exceptions are documented in the reference section.

A string describing a client object is returned by the method [GetIdentity](#) or can be written to the engine's output stream using [OutputIdentity](#).

COM Interfaces

The debugger engine API contains several COM like interfaces; they implement the **IUnknown** interface.

The interfaces described in the section [Debug Engine Interfaces](#) is implemented by the client (though not necessarily at the latest version). You may use the COM method [IUnknown::QueryInterface](#) to obtain each of these interfaces from any of the others.

The clients implement the **IUnknown** COM interface and use it for maintaining reference counts and interface selection. However, the clients are not registered COM objects. The method [IUnknown::AddRef](#) is used to increment the reference count on the object, and the method [IUnknown::Release](#) is used to decrement the reference count. When [IUnknown::QueryInterface](#) is called, the reference count is incremented, so when a client interface pointer is no longer needed [IUnknown::Release](#) should be called to decrement the reference count.

The reference count will be initialized to one when the client object is created using [DebugCreate](#) or [DebugConnect](#).

See the Platform SDK for more information about when reference counts should be incremented and decremented.

IUnknown::QueryInterface, **DebugCreate**, and **DebugConnect** each take an interface ID as one of their arguments. This interface ID can be obtained using the `__uuidof` operator. For example:

```
IDebugClient * debugClient;
HRESULT Hr = DebugCreate( __uuidof(IDebugClient), (void **)&debugClient );
```

Important The `IDebug*` interfaces such as [IDebugEventCallbacks](#) interface, although COM like, are not proper COM APIs. Calling these interfaces from managed code is an unsupported scenario. Issues such as garbage collection and thread ownership, lead to system instability when the interfaces are called with managed code.

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

Using Callback Objects

There are three callback COM like interfaces that are used by the engine: [IDebugEventCallbacks](#) for notifying [debugger extensions](#) and applications of changes to the engine or target, [IDebugInputCallbacks](#) for requesting input, and [IDebugOutputCallbacks](#) for sending output.

Callback objects are registered with clients. At most, one instance of each of the three callback interfaces can be registered with each client (the Unicode and ASCII versions of a interface count as the same interface).

When a client is created, the engine remembers the thread in which it was created. The engine uses this same thread whenever it makes a call to a callback instance registered with the client. If the thread is in use, the engine will queue the calls it needs to make. To allow the engine to make these calls, the method [DispatchCallbacks](#) should be called whenever a client's thread is idle. The method [ExitDispatch](#) will cause [DispatchCallbacks](#) to return. If the thread is the same thread that was used to start the debugger session, then the engine can make the callback calls during the [WaitForEvent](#) method, and [DispatchCallbacks](#) does not need to be called.

The method [FlushCallbacks](#) tells the engine to send all buffered output to the output callbacks.

Event Callback Objects

The [IDebugEventCallbacks](#) interface is used by the engine to notify the debugger extensions and applications of [events](#) and changes to the engine and target. An implementation of [IDebugEventCallbacks](#) can be registered with a client using [SetEventCallbacks](#). The current implementation registered with a client can be found using [GetEventCallbacks](#). The number of event callbacks registered across all clients can be found using [GetNumberEventCallbacks](#).

For details on how the engine manages events, see [Monitoring Events](#).

Input Callback Objects

The [IDebugInputCallbacks](#) interface is used by the engine to request input from debugger extensions and applications. An implementation of [IDebugInputCallbacks](#) can be registered with a client using [SetInputCallbacks](#). The current implementation registered with a client can be found using [GetInputCallbacks](#). The number of input callbacks registered across all clients can be found using [GetNumberInputCallbacks](#).

For details on how the engine manages input, see [Input and Output](#).

Output Callback Objects

The [IDebugOutputCallbacks](#) interface is used by the engine to send output to the debugger extensions and applications. An implementation of [IDebugOutputCallbacks](#)

can be registered with a client using [SetOutputCallbacks](#). The current implementation registered with a client can be found using [GetOutputCallbacks](#). The number of output callbacks registered across all clients can be found using [GetNumberOutputCallbacks](#).

For details on how the engine manages output, see [Input and Output](#).

Note As is typical for COM objects, the engine will call **IUnknown::AddRef** on a callback COM object when it is registered with a client, and **IUnknown::Release** when the object is replaced or the client is deleted.

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

Using Input and Output

For an overview of the input and output streams in the debugger engine, see [Input and Output](#).

Input

The engine will ask for input from all its clients if the [Input](#) method is called on a client. The input is returned to the caller of [Input](#).

Input Callbacks

When the engine asks for input from a client, it uses the [IDebugInputCallbacks](#) object registered with that client. An [IDebugInputCallbacks](#) object may be registered with a client using [SetInputCallbacks](#). Each client can have at most one [IDebugInputCallbacks](#) object registered with it.

The request for input begins with the engine calling the [IDebugInputCallbacks::StartInput](#) method. This informs the [IDebugInputCallbacks](#) object that the engine is now waiting for input.

If the [IDebugInputCallbacks](#) object has some input for the engine, it can call the [ReturnInput](#) method of [any](#) client. Once the [ReturnInput](#) method has been called, the engine will not take any more input. Subsequent callers of this method will be informed that the input was not received.

The engine will then call [IDebugInputCallbacks::EndInput](#) to indicate that it has stopped waiting for input.

Finally, the engine will echo this input to the registered [IDebugOutputCallbacks](#) object of every client (except the one used to provide the input) by using [IDebugOutputCallbacks::Output](#) with the bit-mask set to `DEBUG_OUTPUT_PROMPT`.

Output

Output may be sent to the engine using several client methods -- for example [Output](#) and [OutputVaList](#). Upon receiving output, the engine sends it to some clients.

Clients use an *output mask* to indicate which types of output they are interested in. Whenever output is produced by the engine, it is accompanied by a mask specifying its output type. If the type of output matches the output mask of the client, the client will receive the output. The output mask may be set by calling [SetOutputMask](#) and queried using [GetOutputMask](#). See [DEBUG_OUTPUT_XXX](#) for details of the output mask values.

The list of clients that the engine will send output to is controlled by the *output control*. Typically, the output control is set to send output to all clients; however, it can be temporarily changed using [ControlledOutput](#) and [ControlledOutputVaList](#). See [DEBUG_OUTCTL_XXX](#) for details about output control values.

Output may be buffered by the engine. If multiple pieces of output are passed to the engine, it may collect them and send them to the clients in one large piece. To flush this buffer, use [FlushCallbacks](#).

Each client object has an *output width*, which is the width of the output display for the client object. While this width is only used as a hint, some commands and extension functions format their output based on this width. The width is returned by the [GetOutputWidth](#) method and can be set using the [SetOutputWidth](#) method.

Output Callbacks

When the engine sends output to a client, it uses the [IDebugOutputCallbacks](#) object registered with the client. An [IDebugOutputCallbacks](#) object may be registered with a client using [SetOutputCallbacks](#). Each client can have at most one [IDebugOutputCallbacks](#) object registered with it.

To send the output, the engine calls the [IDebugOutputCallbacks::Output](#) method.

Output Line Prefix

Each client object has an *output line prefix* which is prepended to every line of output sent to the output callback associated with the client object. This can be used for indentation or to place identifying marks on each line of output.

The output line prefix is returned by [GetOutputLinePrefix](#) and can be set using [SetOutputLinePrefix](#). To temporarily change the output line prefix and later change it back again, use [PushOutputLinePrefix](#) and [PopOutputLinePrefix](#).

Log Files

The debugger engine supports opening a log file to record a debugging session. At most, one log file can be open at a time. Output sent to the output callbacks is also sent to this log file (unless it is flagged to not be logged).

To open a log file, use [OpenLogFile2](#) (or [OpenLogFile](#)). The method [GetLogFile2](#) (or [GetLogFile](#)) returns the currently open log file. To close the log file, use [CloseLogFile](#).

The method [SetLogMask](#) can be used to filter the output sent to the log file, and [GetLogMask](#) will return the current log file filter.

Prompt

In an interactive debugging session, a prompt can be used to indicate to the user that the debugger is waiting for user input. The prompt is sent to the output callbacks using the [OutputPrompt](#) and [OutputPromptVaList](#) methods. The contents of the standard prompt are returned by [GetPromptText](#).

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

Monitoring Events

For an overview of events in the [debugger engine](#), see [Events](#).

Events occurring in a target or the debugger engine may be monitored using the [IDebugEventCallbacks](#) interface. An **IDebugEventCallbacks** object may be registered with a client using [SetEventCallbacks](#). Each client can only have at most one **IDebugEventCallbacks** object registered with it.

When an **IDebugEventCallbacks** object is registered with a client, the engine will call the object's [IDebugEventCallbacks::GetInterestMask](#) to determine which events the object is interested in. Only events in which the object is interested will be sent to it.

For each type of event, the engine calls a corresponding callback method on [IDebugEventCallbacks](#). For events from the target, the [DEBUG_STATUS_XXX](#) value returned from these calls specifies how the execution of the target should proceed. The engine collects these return values from each **IDebugEventCallbacks** object it calls and acts on the one with the highest precedence.

Events from the Target That Break into the Debugger by Default

The following events break into the debugger by default:

- Breakpoint Events
- Exception Events (not documented here)
- System Error

Events from the Target that Do Not Break into the Debugger by Default

The following events do not break into the debugger by default:

- Create Process Event
- Exit Process Event
- Create Thread Event
- Exit Thread Event
- Load Module Event
- Unload Module Event

Internal Engine Changes

The following are not actual events, but are merely internal engine changes:

- Target Change
- Engine Change
- Engine Symbol Change
- Session Status Change

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

Event Filters

Event filters provide simple event filtering; they influence how the debugger engine proceeds after an event occurs in a target. When an event occurs, the engine determines whether that event matches an event filter. If it does, the break status for the event filter influences whether the debugger will break into the target. If the event is an exception event, the handling status determines whether the exception should be considered handled or not-handled in the target.

Note If more sophisticated event filtering is required, event callbacks can be used.

Event filters are divided into three categories.

1. *Specific event filters*. These are the filters for all the non-exception events. See [DEBUG FILTER XXX](#) for a list of these events.
2. *Specific exception filters*. The first specific exception filter is the *default exception filter*. The rest are filters for those exceptions for which the engine has built-in filters. See [Specific Exceptions](#) for a list of the specific exception filters.
3. *Arbitrary exception filters*. These are filters for exception events that have been added manually.

The filters in categories 1 and 2 are collectively known as *specific filters*, and the filters in categories 2 and 3 are collectively known as *exception filters*. The number of filters in each category is returned by [GetNumberEventFilters](#).

An event matches a specific event filter if the type of the event is the same as the type of the filter. Some event filters have an additional parameter which further restricts the events they match.

An exception event matches an exception filter if the exception code for the exception event is the same as the exception code for the exception filter. If there is no exception filter with the same exception code as the exception event, the exception event will be handled by the default exception filter.

Commands and Parameters

Event filters can have a debugger command associated with them. This command is executed by the engine when an event matching the filter occurs. [GetEventFilterCommand](#) and [SetEventFilterCommand](#) can be used to get and set this command. For exception filters, this command is executed on the first-chance of the exception. A separate second-chance command can be executed upon the second-chance exception event. To get and set the second-chance command, use [GetExceptionFilterSecondCommand](#) and [SetExceptionSecondChanceCommand](#).

The parameters for specific event filters and exception filters are returned by [GetSpecificFilterParameters](#) and [GetExceptionFilterParameters](#). The break status and handling status for event filters can be set using [SetSpecificFilterParameters](#) and [SetExceptionFilterParameters](#).

[SetExceptionFilterParameters](#) can also be used to add and remove arbitrary exception filters.

A short description of specific filters is returned by [GetEventFilterText](#).

Some specific filters take arguments that restrict which events the filter matches. [GetSpecificFilterArgument](#) and [SetSpecificFilterArgument](#) will get and set arguments for those specific filters which support arguments. If a specific filter has no argument, there is no restriction on which events it matches. The following table lists the event filters that take arguments and how they restrict the events which match them:

Event	Match criteria
Create Process	The name of the created process must match the argument.1
Exit Process	The name of the exited process must match the argument.1
Load Module	The name of the loaded module must match the argument.1
Unload Module	The base address of the unloaded module must be the same as the argument.2
Target Output	The debug output from the target must match the argument.3

Note

1. The argument uses the [string wildcard syntax](#) and is compared with the image name (ignoring path) when the event occurs. If the name of the module or process is not available, it is considered a match.
2. The argument is an expression that is evaluated by the engine when the argument is set.
3. The argument uses the string wildcard syntax and is compared with the debug output from the target. If the output is not known, it is considered a match.

Index and Exception Code

Each event filter has an index. The index is a number between zero and one less than the total number of filters (inclusive). The index range for each category of filters can be found from the *SpecificEvents*, *SpecificExceptions*, and *ArbitraryExceptions* values returned by [GetNumberEventFilters](#), as described in the following table:

Event Filters	Index of first filter	Number of filters
Specific event filters	0	<i>SpecificEvents</i>
specific exception filters	<i>SpecificEvents</i>	<i>SpecificExceptions</i>
arbitrary exception filters	<i>SpecificEvents</i> + <i>SpecificExceptions</i>	<i>ArbitraryExceptions</i>

The indices for the specific event filters are found in the first table located in the topic [DEBUG FILTER XXX](#). The index of the default exception filter (the first specific exception filter) is *SpecificEvents*. When an arbitrary exception filter is removed, the indices of the other arbitrary exception filters can change.

The exception filters are usually specified by exception code. However, some methods require the index of the exception. To find the index of an exception filter for a given exception, use [GetExceptionFilterParameters](#) to iterate over all the exception filters until you find the one with the same exception code as the exception. The exception codes for the specific exception filters can be found in the topic [Specific Exceptions](#).

System Errors

When a system error occurs, the engine will break into the debugger or print the error to the output stream, if the error occurs at or below specified levels. These levels are returned by [GetSystemErrorControl](#) and can be changed using [SetSystemErrorControl](#).

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

Event Information

Whenever a debugging session is accessible, there is a *last event*. This is the event that caused the session to become accessible. The *event target* is the target which generated the last event. When the session becomes accessible, the current target is set to the event target. The details of the last event are returned by [GetLastEventInformation](#). The instruction pointer for the last event and the memory at the instruction pointer when the event occurred are returned by the [Request](#) operations [DEBUG REQUEST GET CAPTURED EVENT CODE OFFSET](#) and [DEBUG REQUEST READ CAPTURED EVENT CODE STREAM](#).

If the target is a crash dump file, the *last event* is the last event that occurred before the dump file was created. This event is stored in the dump file and the engine generates it for the event callbacks when the dump file is acquired as a debugging target.

If the target is a kernel-mode target and a *bug check* occurred, the bug check code and related parameters can be found using [ReadBugCheckData](#).

If the target is a user-mode Minidump, the dump file generator may store an additional event. Typically, this is the event that provoked the generator to save the dump file. Details of this event are returned by [GetStoredEventInformation](#) and the [Request](#) operations [DEBUG REQUEST TARGET EXCEPTION CONTEXT](#), [DEBUG REQUEST TARGET EXCEPTION THREAD](#), and [DEBUG REQUEST TARGET EXCEPTION RECORD](#).

Dump files may contain a static list of events. Each event represents a snapshot of the target at a particular point in time. The number of events in this list is returned by [GetNumberEvents](#). For a description of each event in the list, use [GetEventIndexDescription](#). To set an event from this list as the current event, use the method [SetNextEventIndex](#); after calling [WaitForEvent](#), the event becomes the current event. To determine which event in the list is the current event, use [GetCurrentEventIndex](#).

Using Breakpoints

Breakpoints are event triggers which, when the breakpoint's conditions are satisfied, will halt execution of the target and break into the debugger. Breakpoints allow the user to analyze and perhaps modify the target when execution reaches a certain point or when a certain memory location is accessed.

The debugger engine inserts a *software breakpoint* into a target by modifying the processor instruction at the breakpoint's location; this modification is invisible to the engine's clients. A software breakpoint is triggered when the target executes the instruction at the breakpoint location. A *processor breakpoint* is inserted into the target's processor by the debugger engine; its capabilities are processor-specific. It is triggered by the processor when the memory at the breakpoint location is accessed; what type of access will trigger this breakpoint is specified when the breakpoint is created.

This topic includes:

[Setting Breakpoints](#)[Controlling Breakpoint Flags and Parameters](#)[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

Setting Breakpoints

Breakpoints are created with the [AddBreakpoint](#) method. This method creates an [IDebugBreakpoint](#) object that represents the breakpoint. It also set the *breakpoint type* (software breakpoint or processor breakpoint). Once a breakpoint has been created, its type cannot be changed.

Breakpoints are deleted with the [RemoveBreakpoint](#) method. This also deletes the [IDebugBreakpoint](#) object; this object may not be used again.

Note Although [IDebugBreakpoint](#) implements the [IUnknown](#) interface, the methods [IUnknown::AddRef](#) and [IUnknown::Release](#) are not used to control the lifetime of the breakpoint. These methods have no effect on the lifetime of the breakpoint. Instead, an [IDebugBreakpoint](#) object is deleted after the method [RemoveBreakpoint](#) is called.

When the breakpoint is created, it is given a unique *breakpoint ID*. This identifier will not change. However, after the breakpoint has been deleted, its ID may be used for another breakpoint. For details on how to receive notification of the removal of a breakpoint, see [Monitoring Events](#).

When a breakpoint is created, it is initially disabled; this means that it will not cause the target to stop executing. This breakpoint may be enabled by using the method [AddFlags](#) to add the [DEBUG_BREAKPOINT_ENABLED](#) flag.

When a breakpoint is first created, it has the memory location 0x00000000 associated with it. The location can be changed by using [SetOffset](#) with an address, or by using [SetOffsetExpression](#) with a symbolic expression. The breakpoint's location should be changed from its initial value before it is used.

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

Controlling Breakpoint Flags and Parameters

There are a number of methods that can be used to determine basic information about breakpoints:

- [GetId](#) returns the breakpoint ID.
- [GetType](#) returns the breakpoint type (software or processor) and the type of the effective processor on which the breakpoint is set.
- [GetAdder](#) returns the client that added the breakpoint.
- [GetOffset](#) returns the address of a breakpoint.
- [GetOffsetExpression](#) returns the expression string that specifies the location of the breakpoint.

In addition to its location and breakpoint type, a breakpoint has several parameters controlling its behavior.

Breakpoint parameters can be controlled through a variety of specific methods. In addition, most of the parameters may be queried together using [GetParameters](#).

Breakpoint Flags

Breakpoint flags are one kind of breakpoint parameters.

Breakpoint flags can be queried using [GetFlags](#). They can be changed by using [AddFlags](#), [RemoveFlags](#), or [SetFlags](#).

Breakpoint flags form a bit field. The possible flags that can be used in this bit field, and their meanings, are as follows:

DEBUG_BREAKPOINT_ENABLED

When this flag is set, the breakpoint is *enabled* and will have its normal effect. When this flag is not set, the breakpoint is *disabled* and will not have any effect. If you wish to temporarily deactivate a breakpoint, you can remove this flag; it is then easy to add this flag back when you want to re-enable this breakpoint.

DEBUG_BREAKPOINT_ADDER_ONLY

When this flag is set, the breakpoint is a *private breakpoint*. This breakpoint is visible only to the client that added it. In this case, other clients will not be able to query the engine for the breakpoint, and the engine will not send events generated by the breakpoint to other clients. All callbacks (event and [output](#)) related to this breakpoint will be sent only to this client. See [GetAdder](#).

DEBUG_BREAKPOINT_GO_ONLY

When this flag is set, the breakpoint will only be triggered if the target is in unrestricted execution. It will not be triggered if the engine is stepping through instructions in the target.

DEBUG_BREAKPOINT_ONE_SHOT

When this flag is set, the breakpoint will automatically remove itself the first time it is triggered.

DEBUG_BREAKPOINT_DEFERRED

When this flag is set, the breakpoint is *deferred*. This flag is set by the engine when the offset of the breakpoint is specified using a symbolic expression, and the engine cannot evaluate the expression. Every time a module is loaded or unloaded in the target, the engine will attempt reevaluate the expression for all breakpoints whose location is specified using an expression. Those that cannot be evaluated are flagged as deferred. [This flag cannot be modified by any client](#).

Other Breakpoint Parameters

Breakpoint parameters also include:

Pass count

If the breakpoint has a pass count associated with it, it will not be activated until the target has passed the breakpoint the specified number of times. The pass count that was originally set can be found by using [GetPassCount](#). The number of times remaining that the engine will pass the breakpoint before it is activated can be found using [GetCurrentPassCount](#). The pass count can be reset to a new value by using [SetPassCount](#).

Match thread

If the breakpoint has a thread associated with it, it will be ignored by the engine when it is encountered by any other thread. The thread can be found by using [GetMatchThreadId](#), and can be changed by using [SetMatchThreadId](#).

Command

The breakpoint may have a command associated with it. The command is executed when the breakpoint is activated. This command can be found by using [GetCommand](#), and can be changed by using [SetCommand](#).

Size

If the breakpoint is a processor breakpoint, it must have a specified size. This determines the size of the block of memory whose access will activate the breakpoint -- the beginning of the block is the breakpoint's location. The size can be found by using [GetDataParameters](#), and can be changed by using [SetDataParameters](#).

Access type

If the breakpoint is a processor breakpoint, it must have an access type. This determines the type of access that will activate the breakpoint. For example, the breakpoint may be activated if the target reads from, writes to, or executes the memory specified by the breakpoint. The access type can be found by using [GetDataParameters](#), and can be changed by using [SetDataParameters](#).

Valid Parameters for Processor Breakpoints

The following access types are available for processor breakpoints:

Value	Description
DEBUG_BREAK_READ	The breakpoint will be triggered when the CPU reads memory in the breakpoint's memory block.
DEBUG_BREAK_WRITE	The breakpoint will be triggered when the CPU writes memory in the breakpoint's memory block.
DEBUG_BREAK_READ DEBUG_BREAK_WRITE	The breakpoint will be triggered when the CPU reads or writes memory in the breakpoint's memory block.
DEBUG_BREAK_EXECUTE	The breakpoint will be triggered when the CPU fetches the instruction in the breakpoint's memory block.
DEBUG_BREAK_IO	The breakpoint will be triggered when the I/O port in the breakpoints memory block is accessed. (Windows XP and Microsoft Windows Server 2003 only, kernel mode only, x86 only)

Not all access types and sizes are supported on all processors. The following access types and sizes are supported:

x86

All access types are supported. DEBUG_BREAK_READ behaves like DEBUG_BREAK_READ | DEBUG_BREAK_WRITE. The size must be 1, 2, or 4. The breakpoint's address must be a multiple of the size.

x64

All access types are supported. DEBUG_BREAK_READ behaves like DEBUG_BREAK_READ | DEBUG_BREAK_WRITE. The size must be 1, 2, 4, or 8. The breakpoint's address must be a multiple of the size.

Itanium

All access types except DEBUG_BREAK_IO are supported. The size must be a power of two; for DEBUG_BREAK_EXECUTE, the size must be 16. The breakpoint's address must be a multiple of the size.

Itanium running in x86 mode

The is the same as for x86, except that DEBUG_BREAK_IO is not supported.

Memory Access

The [debugger engine](#) provides *interfaces* to directly read from and write to the target's main memory, registers, and other data spaces.

In user-mode debugging, only the virtual memory and registers can be accessed; the physical memory and other data spaces cannot be accessed.

The debugger engine API always uses 64-bit addresses when referring to memory locations on the target.

If the target uses 32-bit addresses, the native 32-bit address will automatically be sign-extended by the engine to 64-bit addresses. The engine will automatically convert between 64-bit addresses and native 32-bit addresses when communicating with the target.

This section includes:

[Virtual and Physical Memory](#)

[Registers](#)

[Other Data Spaces](#)

[Send comments about this topic to Microsoft](#)

Virtual and Physical Memory

The engine provides a number of methods for reading and writing the virtual and physical memory of a target.

Virtual Memory

When specifying a location in the virtual memory of a target, the target's virtual address space is used. In user-mode debugging, this is the virtual address space of the current process. In kernel-mode debugging, this is the virtual address space of the implicit process. See [Threads and Processes](#) for more information about the current and implicit process.

The virtual memory (of the target) can be read by using [ReadVirtual](#) and written using [WriteVirtual](#).

Pointers in the target's memory can be read and written by using the convenience methods [ReadPointersVirtual](#) and [WritePointersVirtual](#). These methods will automatically convert between the 64-bit pointers used by the engine and the native pointers used by the target. These methods are useful when requesting memory that contains pointers that will be used for subsequent requests -- for example, a pointer to a string.

The [SearchVirtual](#) and [SearchVirtual2](#) methods can be used to search the target's virtual memory for a pattern of bytes.

The [FillVirtual](#) method can be used to copy a pattern of bytes, multiple times, to the target's virtual memory.

The target's virtual memory can also be read and written in a way that bypasses the debugger engine's virtual memory cache using the methods [ReadVirtualUncached](#) and [WriteVirtualUncached](#). These uncached versions are useful for reading virtual memory that is inherently volatile, such as memory-mapped device areas, without contaminating or invalidating the cache. Uncached memory access should only be used in situations when it is required, as the performance of uncached access can be significantly lower than cached access.

The engine provides some convenience methods to read strings from the target's virtual memory. To read a multibyte string from the target, use [ReadMultiByteStringVirtual](#) and [ReadMultiByteStringVirtualWide](#). To read a Unicode string from the target, use [ReadUnicodeStringVirtual](#) and [ReadUnicodeStringVirtualWide](#).

To find information about a memory location, use [GetOffsetInformation](#). Not all of the virtual address space in the target contains valid memory. To find valid memory within a region, use [GetValidRegionVirtual](#). When manually searching for valid memory in a target, the method [GetNextDifferentlyValidOffsetVirtual](#) will find the next location where the validity may change.

Physical Memory

The physical memory can only be directly accessed in kernel-mode debugging.

Physical memory on the target can be read by using [ReadPhysical](#) and [ReadPhysical2](#), and written by using [WritePhysical](#) and [WritePhysical2](#).

The [FillPhysical](#) method can be used to copy a pattern of bytes, multiple times, to the target's physical memory.

An address in the target's virtual address space can be translated to a physical address on the target by using the [VirtualToPhysical](#) method. The system's paging structures used to translate a virtual address to a physical address can be found by using [GetVirtualTranslationPhysicalOffsets](#).

Events

When the virtual or physical memory of the target is changed, the [IDebugEventCallbacks::ChangeDebuggeeState](#) callback method is called.

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

Registers

The [debugger engine](#) can be used to examine and alter the target's registers.

The registers available on the target depend on its processor architecture. For a description of the registers for the x86 and Itanium processors, see [Processor Architecture](#). For a complete description of the registers available for a processor, see that processor's documentation.

The Register Set

The [GetNumberRegisters](#) method can be used to find the number of registers on the target.

Each register is referred to by its index. The index of the first register is zero, and the index of the last register is the number of registers minus one. To find the index of a register whose name is known, use [GetIndexByName](#).

The method [GetDescription](#) returns information about a register. This includes the register's name, the type of values it can hold, and whether it is a subregister.

A *subregister* is a register that is contained within another register. When the subregister changes, the register that contains it also changes. For example, on an x86 processor, the **ax** subregister is the same as the low 16 bits of the 32-bit **eax** register.

There are three special registers whose values may be found by using the following methods. The interpretation of the values of these registers is platform dependent.

- The location of the current instruction may be found with [GetInstructionOffset](#) and [GetInstructionOffset2](#).
- The location of the current processor stack slot may be found with [GetStackOffset](#) and [GetStackOffset2](#).
- The location of the stack frame for the current function may be found with [GetFrameOffset](#) and [GetFrameOffset2](#).

Manipulating Registers

The value of a register can be read by using the method [GetValue](#). Multiple registers can be read by using [GetValues](#) and [GetValues2](#).

A value can be written to a register by using the method [SetValue](#). Multiple registers can be written by using [SetValues](#) and [SetValues2](#).

When writing a value to a register, if the value supplied has a different type to the type of the register then the value is converted into the register's type. This conversion is the same as that performed by the method [CoerceValue](#). This conversion may result in data loss if the register's type is not capable of holding the value supplied.

Pseudo-Registers

Pseudo-registers are variables maintained by the debugger engine that hold certain values, for example, \$teb is the name of the pseudo-register whose value is the address of the current thread's Thread Environment Block (TEB). For more information, and a list of the pseudo-registers, see [Pseudo-Register Syntax](#).

Each pseudo-register has an index. The index is a number between zero and the number of pseudo-registers - (returned by [GetNumberPseudoRegisters](#)) minus one. To find the index of a pseudo-register by its name, use [GetPseudoIndexByName](#). The values of pseudo-registers can be read using [GetPseudoValues](#), and values can be written to pseudo-registers using [SetPseudoValues](#). For a description of a pseudo-register, including its type, use [GetPseudoDescription](#).

Note Not all of the pseudo-registers are available in all debugging sessions or at all times in a particular session.

Displaying Registers

The methods [OutputRegisters](#) and [OutputRegisters2](#) format the target's registers and sends them to the clients as output.

Events

Whenever the values of the target's registers change, the engine will call the [IDebugEventCallbacks::ChangeDebuggeeState](#) callback method with the parameter *Flags* set to DEBUG_CDS_REGISTERS.

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

Other Data Spaces

In kernel-mode debugging, it is possible to read and write data to a variety of data spaces in addition to the main memory and registers. The following data spaces can be accessed:

System Bus

The methods [ReadBusData](#) and [WriteBusData](#) read and write system bus data.

Control-Space Memory

The methods [ReadControl](#) and [WriteControl](#) read and write control-space memory.

I/O Memory.

The methods [ReadIo](#) and [WriteIo](#) read and write system and bus I/O memory.

Model Specific Register (MSR)

The methods [ReadMsr](#) and [WriteMsr](#) read and write MSRs, which are control registers that enable and disable features, and support debugging, for a particular model of CPU.

Handles

In user-mode debugging, information about system objects can be obtained using system handles owned by a target process. The method [ReadHandleData](#) can be used to read this information.

System handles for thread and process system objects can be obtained by using the [GetCurrentThreadHandle](#) and [GetCurrentProcessHandle](#) methods. These handles are also provided to the [IDebugEventCallbacks::CreateThread](#) and [IDebugEventCallbacks::CreateProcess](#) callback methods when create-thread and create-process debugging event occur.

Note In kernel mode, the process and thread handles are artificial handles. They are not system handles.

[Send comments about this topic to Microsoft](#)

Examining the Stack Trace

A *call stack* contains the data for the function calls made by a thread. The data for each function call is called a *stack frame* and includes the return address, parameters passed to the function, and the function's local variables. Each time a function call is made a new stack frame is pushed onto the top of the stack. When that function returns, the stack frame is popped off the stack.

Each thread has its own call stack, representing the calls made in that thread.

To get a stack trace, use the methods [GetStackTrace](#) and [GetContextStackTrace](#). A stack trace can be printed using [OutputStackTrace](#) and [OutputContextStackTrace](#).

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

Controlling Threads and Processes

For an overview of threads and processes in the debugger engine, see [Threads and Processes](#).

When an event occurs, the event thread and event process are set to the thread and process (operating system or virtual) in which the event occurred. They can be found using [GetEventThread](#) and [GetEventProcess](#), respectively.

Implicit Threads and Processes

In kernel-mode debugging the debugger engine will use the *implicit process* to determine which virtual address space to use when performing virtual to physical address translation -- for example, in the methods [VirtualToPhysical](#) and [ReadVirtual](#). When an event occurs, the implicit process is set to the current process.

The implicit process may be changed by using [SetImplicitProcessDataOffset](#). To determine the implicit process use [GetImplicitProcessDataOffset](#).

Note When setting [breakpoints](#) during a live kernel debugging session, the debugger engine will pass the virtual address of the breakpoint to the target, and the target will set the breakpoint. In this case, only the process context of the target is used when handling the breakpoint; the value of the implicit process is irrelevant.

In kernel-mode debugging, the debugger engine will use the *implicit thread* to determine some of the target's [registers](#). This includes the processor stack (see [GetStackOffset](#)), the frame offset (see [GetFrameOffset](#)), and the instruction offset (see [GetInstructionOffset](#)). When an event occurs, the implicit thread is set to the current thread.

The implicit thread may be changed by using [SetImplicitThreadIdDataOffset](#). To determine the implicit thread, use [GetImplicitThreadIdDataOffset](#).

Not all registers are determined by the implicit thread. Some registers will remain the same when the implicit thread is changed.

Warning The implicit process and implicit thread are independent. If the implicit thread does not belong to the implicit process, then user and session state for the implicit thread will be in the wrong virtual address space and attempts to access this information will cause errors or provide incorrect results. This problem does not occur when accessing kernel memory, since kernel memory addresses are constant across all virtual address spaces. Thus information for the implicit thread located in kernel memory may be accessed independent of the implicit process.

Threads

The *engine thread ID* is used by the debugger engine to identify each operating system thread and each virtual thread for a target.

While a target is stopped, each thread also has an index relative to the process to which it belongs. For any process, the index of the first thread in the process is zero, and the index of the last thread is the number of threads in the process minus one. The number of threads in the current process can be found by using [GetNumberOfThreads](#). The total number of threads in all processes in the current target can be found by using [GetTotalNumberOfThreads](#).

The engine thread ID and system thread ID for one or more threads in the current process can be found from their index by using [GetThreadIdsByIndex](#).

The engine maintains several pieces of information about each thread. This information may be queried for the current thread, and may be used to find the engine thread ID for a thread.

system thread ID (user-mode debugging only)

The system thread ID of the current thread can be found by using [GetCurrentThreadSystemId](#). For a given system thread ID, the corresponding engine thread ID may be found by using [GetThreadIdBySystemId](#).

thread environment block (TEB)

The address of the TEB for the current thread can be found by using [GetCurrentThreadTeb](#). For a given TEB address, the corresponding engine thread ID may be found by using [GetThreadIdByTeb](#). In kernel-mode debugging, the TEB of a (virtual) thread is the TEB of the system thread that was running on the corresponding processor when the last event occurred.

data offset

In user-mode debugging, the data offset of a (system) thread is the location of the TEB for that thread. In kernel-mode debugging the data offset of a (virtual) thread is the KTHREAD structure for the system thread that was running on the corresponding processor when the last event occurred. The data offset of the current thread can be found by using [GetCurrentThreadDataOffset](#). For a given data offset, the corresponding engine thread ID may be found by using [GetThreadIdByDataOffset](#).

system handle

The system handle of the current thread can be found by using [GetCurrentThreadHandle](#). For a given system handle, the corresponding engine thread ID may be found by using [GetThreadIdByHandle](#). In kernel-mode debugging, an artificial handle is created for each (virtual) process. This handle can only be used with debugger engine API queries.

Processes

The *engine process ID* is used by the debugger engine to identify each operating system process and each virtual process for a target.

While a target is stopped, each process has an index relative to the target. The index of the first process in the target is zero, and the index of the last process is the number of processes in the target minus one. The number of processes in the current target can be found by using [GetNumberOfProcesses](#).

The engine process ID and system process ID for one or more threads in the current target can be found from their index by using [GetProcessIdsByIndex](#).

The engine maintains several pieces of information about each process. This information may be queried for the current process, and may be used to find the engine process ID for a process.

system process ID (user-mode debugging only)

The system process ID of the current process can be found by using [GetCurrentProcessSystemId](#). For a given system process ID, the corresponding engine process ID may be found by using [GetProcessIdBySystemId](#).

process environment block (PEB)

The address of the PEB for the current process can be found by using [GetCurrentProcessPeb](#). For a given PEB address, the corresponding engine process ID may be found by using [GetProcessIdByPeb](#). In kernel-mode debugging, the PEB of the (virtual) process is the PEB of the system process that was running when the last event occurred.

data offset

In user-mode debugging, the data offset of a (system) process is the location of the PEB of that process. In kernel-mode debugging, the data offset of the (virtual) process is the KPROCESS structure for the system process that was running when the last event occurred. The data offset of the current process can be found by using [GetCurrentProcessDataOffset](#). For a given data offset, the corresponding engine process ID may be found by using [GetProcessIdByDataOffset](#).

system handle

The system handle of the current process can be found by using [GetCurrentProcessHandle](#). For a given system handle, the corresponding engine process ID may be found by using [GetProcessIdByHandle](#). In kernel-mode debugging, an artificial handle is created for the (virtual) process. This handle can only be used with debugger engine queries.

Events

In live user-mode debugging, whenever a thread is created or exits in a target, the create-thread and exit-thread debugging events are generated. These events result in calls to the [IDebugEventCallbacks::CreateThread](#) and [IDebugEventCallbacks::ExitThread](#) callback methods.

In live user-mode debugging, whenever a process is created or exits in a target, the create-process and exit-process debugging events are generated. These events result in calls to the [IDebugEventCallbacks::CreateProcess](#) and [IDebugEventCallbacks::ExitProcess](#) callback methods.

For more information about events, see [Monitoring Events](#).

Additional Information

For more information about threads and processes, including the TEB, KTHREAD, PEB, and KPROCESS structures, see *Microsoft Windows Internals* by David Solomon and Mark Russinovich.

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

Using Symbols

For an overview of symbols, including using symbol files and symbol servers, see [Symbols](#).

Symbol Names and Locations

To find the location of a symbol given its name, use [GetOffsetByName](#). For details on the syntax used to specify symbol names, see [Symbol Syntax and Symbol Matching](#).

If the exact name of a symbol is not known, or multiple symbols have the same name, [StartSymbolMatch](#) will begin a search for symbols whose names match a given pattern. For details on the syntax, see [String Wildcard Syntax](#).

To find the name of a symbol given its location, use [GetNameByOffset](#). To find the names of symbols in a module near a given location, use [GetNearNamebyOffset](#).

Note Whenever possible, qualify the symbol with the module name -- for example `mymodule!main`. Otherwise, if the symbol does not exist (for example, because of a typographical error) the engine will have to load and search the symbols for every module; this can be a slow process, especially for kernel-mode debugging. If the symbol name was qualified with a module name, the engine will only need to search the symbols for that module.

A symbol is uniquely identified using the structure [DEBUG_MODULE_AND_ID](#). This structure is returned by the methods [GetSymbolEntriesByName](#) and [GetSymbolEntriesByOffset](#), which search for symbols based on their name and location, respectively.

The method [GetSymbolEntryInformation](#) returns a description of a symbol using the [DEBUG_SYMBOL_ENTRY](#) structure.

To find the offset of a field within a structure, use [GetFieldOffset](#). To find the name of a field given its index within a structure, use [GetFieldName](#). To find the name of an enumeration constant given its value, use [GetConstantName](#).

The method [GetSymbolInformation](#) can perform several requests for information about symbols.

Symbol Options

A number of options control how the symbols are loaded and unloaded. For a description of these options, see [Setting Symbol Options](#).

Symbol options may be turned on by using [AddSymbolOptions](#), and turned off by using [RemoveSymbolOptions](#).

[GetSymbolOptions](#) returns the current symbol options. To set all the symbol options at once, use [SetSymbolOptions](#).

Reloading Symbols

After loading symbol files, the engine stores the symbol information in an internal cache. To flush this cache, use [Reload](#). These symbols will have to be loaded again now or at a later time.

Synthetic Symbols

Synthetic symbols are a way to label an arbitrary address for easy reference. Synthetic symbols can be created in any existing module. The method [AddSyntheticSymbol](#) creates a new synthetic symbol. Synthetic symbols can be removed using [RemoveSyntheticSymbol](#). Reloading the symbols for the module deletes all synthetic symbols associated with that module.

Symbol Path

To add a directory or symbol server to the symbol path, use the method [AppendSymbolPath](#). The whole symbol path is returned by [GetSymbolPath](#) and can be changed using [SetSymbolPath](#).

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

Modules

An *image* is an executable, DLL, or driver that Windows has loaded as part of a user-mode process or the kernel. The file from which the image was loaded is referred to as its *image file*.

The [debugger engine](#) caches a list of *modules* for each process (or, in kernel-mode, the virtual process). Typically each module in this list represents an image in the process. The engine's module list can be synchronized with the target using [Reload](#).

Note In kernel-mode debugging, the engine's module list for the virtual process contains both the system-wide kernel-mode modules and the current process's user-mode modules.

A module can be specified by its base address in the target's virtual address space, or by its index in the list of modules the engine maintains for the target. The module's index equals its position in the list of modules, and therefore this index will change if a module with a lower index is unloaded. All unloaded modules have indexes; these are always higher than the indexes of loaded modules. The base address of a module will not change as long as it remains loaded; in some cases it may change if the module is unloaded and then reloaded.

The index is a number between zero and the number of modules in the target minus one. The number of modules in the current process can be found by calling [GetNumberModules](#).

The index can be used to find the base address by calling [GetModuleByIndex](#). The base address of a module owning a symbol with a given name can be found using [GetSymbolModule](#).

The following methods return both the index and base address of the specified module:

- To find a module with a given module name, use [GetModuleByModuleName](#).
- The module whose virtual address range contains a given address is returned by [GetModuleByOffset](#). This method can be used to find the module index given the base address of the module.

The following methods return information about modules specified either by base address or index:

- The names of a module are returned by [GetModuleNames](#) and [GetModuleNameString](#).
- Version information for the module is returned by [GetModuleVersionInformation](#).
- Some of the parameters used to describe a module are returned by [GetModuleParameters](#). For details on the parameters returned by this method, see [DEBUG_MODULE_PARAMETERS](#).

Unloaded Modules

During user-mode debugging, unloaded modules are tracked only in Windows Server 2003 and later versions of Windows. Earlier versions of Windows only tracked unloaded modules in kernel mode. When they are tracked, they are indexed after the loaded modules. Hence any method that searches the target's modules will search all the loaded modules and then the unloaded modules. Unloaded modules can be used to analyze failures caused by an attempt to call unloaded code.

Synthetic Modules

Synthetic modules can be created as a way to label a region of memory. These modules cannot contain real symbols, but they can contain synthetic symbols. The method

[AddSyntheticModule](#) creates a new synthetic module. Synthetic modules can be removed using [RemoveSyntheticModule](#). Reloading all the modules in the target deletes all synthetic modules.

Image Path

The *executable image path* is used by the engine when searching for executable images.

The executable image path can consist of several directories separated by semicolons (;). These directories are searched in order.

For an overview of the executable image path, see [Executable Image Path](#).

To add a directory to the executable image path, use the method [AppendImagePath](#). The whole executable image path is returned by [GetImagePath](#) and can be changed using [SetImagePath](#).

Additional Information

For more information about processes and virtual processes, see [Threads and Processes](#).

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

Types

Type information from a module's symbol file is identified by two pieces of information: a type ID and the base address of the module to which the type belongs. The following methods can be used to find a type ID:

- [GetTypeId](#) returns the type ID for a given type name.
- [GetSymbolTypeId](#) returns the type ID for the type of a symbol with the given name.
- [GetOffsetTypeId](#) returns the type ID for the symbol found at the given location.

The name and size of a type are returned by [GetType](#) and [GetTypeSize](#), respectively.

The following convenience methods can be used for reading and writing typed data in the target's physical and virtual memory:

[ReadTypedDataPhysical](#)
[WriteTypedDataPhysical](#)
[ReadTypedDataVirtual](#)
[WriteTypedDataVirtual](#)

Printing Typed Data

To format typed data and send it to the output callbacks, use [OutputTypedDataPhysical](#) and [OutputTypedDataVirtual](#) for data in the target's physical and virtual memory respectively.

The type options described in [DEBUG_TYPEOPTS_XXX](#) affect how the engine formats typed data before sending it to the output callbacks.

The type options may be turned on by using [AddTypeOptions](#), and turned off by using [RemoveTypeOptions](#).

[GetTypeOptions](#) returns the current type options. To set all the type options at once, use [SetTypeOptions](#).

Interpreting Raw Data Using Type Information

The debugger engine API supports interpreting typed data. This provides a way to walk object hierarchies on the target, including finding members of structures, dereferencing pointers, and locating array elements.

Typed data is described by instances of the [DEBUG_TYPED_DATA](#) structure and represents regions of memory on the target cast to a particular type. The [DEBUG_REQUEST_EXT_TYPED_DATA_ANSI](#) Request operation is used to manipulate these instances. They can be initialized to the result of expressions or by casting regions of memory to a specified type. For a list of all the sub-operations that the DEBUG_REQUEST_EXT_TYPED_DATA_ANSI Request operation supports, see [EXT_TDOP](#).

Additional Information

For details on output callbacks, see [Input and Output](#).

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

Scopes and Symbol Groups

A *symbol group* contains a set of symbols for efficient manipulation as a group. A symbol group can be created and populated manually or can be automatically generated and updated based on symbols in lexical scopes, such as local variables and function arguments. The interface [IDebugSymbolGroup](#) is used to represent a symbol group.

There are two ways to create a symbol group. An empty symbol group is returned by [CreateSymbolGroup](#), and the symbol group for the current lexical scope is returned by [GetScopeSymbolGroup](#).

Note The symbol group generated from the current scope is a snapshot of the local variables. If any execution occurs in the target, the symbols may no longer be accurate. Also, if the current scope changes, the symbol group will no longer represent the *current* scope (because it will continue to represent the scope for which it was created).

Symbols can be added to a symbol group using [AddSymbol](#), and removed using [RemoveSymbolByIndex](#) or [RemoveSymbolByName](#). The method [OutputAsType](#) tells the debugger to use a different symbol type when handling a symbol's data.

Note The values for scoped symbols may not be accurate. In particular, the machine architecture and compiler optimizations may prevent the debugger from accurately determining a symbol's value.

The *symbol entry information* is a description of a symbol, including its location and its type. To find this information for a symbol in a module, use the [IDebugSymbols3::GetSymbolEntryInformation](#). To find this information for a symbol in a symbol group, use [IDebugSymbolGroup2::GetSymbolEntryInformation](#). See [DEBUG_SYMBOL_ENTRY](#) for details of the symbol entry information.

The following methods return information about a symbol in a symbol group:

- [GetSymbolName](#) returns the name of the symbol.
- [GetSymbolOffset](#) returns the absolute address in the target's virtual address space of the symbol, if the symbol has an absolute address.
- [GetSymbolRegister](#) returns the register containing the symbol, if the symbol is contained in a register.
- [GetSymbolSize](#) returns the size of the data for the symbol.
- [GetSymbolTypeName](#) returns the name of the symbol's type.
- [GetSymbolValueText](#) returns the value of the symbol as a string.

If a symbol is stored in a register or in a memory location known to the debugger engine, its value can be changed using [WriteSymbol](#).

A symbol is a *parent symbol* if it contains other symbols. For example, a structure contains its members. A symbol is a *child symbol* if it is contained in another symbol. A symbol may be both a parent and child symbol. Each symbol group has a flat structure and contains parent symbols and their children. Each symbol has a *depth* -- symbols without parents in the symbol group have a depth of zero, and the depth of each child symbol is one greater than the depth of its parent. The children of a parent symbol may or may not be present in the symbol group. When the children are present in the symbol group, the parent symbol is referred to as *expanded*. To add or remove the children of a symbol in a symbol group, use [ExpandSymbol](#).

The number of symbols in a symbol group is returned by [GetNumberSymbols](#). The *index* of a symbol in a symbol group is an identification number; the index ranges from zero to the number of symbols minus one. Each time a symbol is added to or removed from a symbol group -- for example, by expanding a symbol -- the index of all the symbols in the symbol group may change.

The symbol parameters, including information about parent-child relationships, can be found by using [GetSymbolParameters](#). This method returns a [DEBUG_SYMBOL_PARAMETERS](#) structure.

The symbols in a symbol group can be printed to the debugger's output stream using the method [OutputSymbols](#).

Scopes

The *current scope*, or *current local context*, determines the local variables exposed by the debugger engine. The scope has three components:

1. A stack frame.
2. A current instruction.
3. A register context.

If the stack frame is at the top of the call stack, the current instruction is the instruction that resulted in the last event. Otherwise the current instruction is the function call which resulted in the next higher stack frame.

The methods [GetScope](#) and [SetScope](#) can be used to get and set the current scope. When an event occurs, the current scope is set to the scope of the event. The current scope can be reset to the scope of the last event using [ResetScope](#).

Thread Context

The *thread context* is the state preserved by Windows when switching threads. This is similar to the register context, except that there is some kernel-only processor state that is part of the register context but not the thread context. This extra state is available as registers during kernel-mode debugging.

The thread context is represented by the CONTEXT structure defined in ntddk.h. This structure is platform-dependent and its interpretation depends on the effective processor type. The methods [GetThreadContext](#) and [SetThreadContext](#) can be used to get and set the thread context.

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

Using Source Files

The [debugger engine](#) maintains a *source path*, which is a list of directories and source servers that contain source code files associated with the current targets. The debugger engine can search these directories and source servers for the source files. With the help of symbol files, the debugger engine can match lines in the source files with locations in the target's memory.

For an overview of using source files with debuggers, see [Debugging in Source Mode](#). For an overview of source paths, see [Source Path](#). For an overview of using source servers from the debugger engine, see [Using a Source Server](#).

Source Path

To add a directory or source server to the source path, use the method [AppendSourcePath](#). The whole source path is returned by [GetSourcePath](#) and can be changed using [SetSourcePath](#). A single directory or source server can be retrieved from the source path using [GetSourcePathElement](#).

To find a source file relative to the source path, use [FindSourceFile](#) or, for more advanced options when using source servers, use [FindSourceFileAndToken](#). [FindSourceFileAndToken](#) can also be used along with [GetSourceFileInformation](#) to retrieve variables related to a file on a source server.

Matching Source Files to Code in Memory

The debugger engine provides three methods for locating the memory locations that correspond to lines in a source file. To map a single line of source code to a memory location, use [GetOffsetByLine](#). To search for memory locations for more than one source line or for nearby source lines, use [GetSourceEntriesByLine](#). The [GetSourceFileLineOffsets](#) method will return the memory location of every line in a source file.

To perform the opposite operation and find the line of a source file that matches a location in the target's memory, use [GetLineByOffset](#).

Note The relationship between memory locations and lines in a source file is not necessarily one-to-one. It is possible for a single line of source code to correspond to multiple memory locations and for a single memory location to correspond to multiple lines of source code.

Connecting to Targets

This section includes:

[Live User-Mode Targets](#)[Live Kernel-Mode Targets](#)[Dump-File Targets](#)[Remote Targets](#)[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

Live User-Mode Targets

The methods for creating and attaching to processes that are listed in this topic can be used for the local computer and for a remote computer running a process server.

A user-mode process can be created using [Create Process](#) or [CreateProcess2](#), which execute a given command to create a process. The method [AttachProcess](#) can be used to attach the [debugger engine](#) to an existing user-mode process. [CreateProcessAndAttach](#) and [CreateProcessAndAttach2](#) create a new user-mode process and attach to it or another user-mode process on the same computer. The [Request](#) operations [DEBUG REQUEST GET ADDITIONAL CREATE OPTIONS](#), [DEBUG REQUEST SET ADDITIONAL CREATE OPTIONS](#), and [DEBUG REQUEST SET LOCAL IMPLICIT COMMAND LINE](#) can be used to set some of the default options for creating processes.

Note The engine doesn't completely attach to the process until the [WaitForEvent](#) method has been called. Only after the process has generated an event -- for example, the process creation event -- does it become available in the debugger session. See [Debugging Session and Execution Model](#) for more details.

The method [GetRunningProcessSystemIds](#) will return the process IDs of all the running processes on the computer. The process ID of a particular program can be found using [GetRunningProcessSystemIdByExecutableName](#). Given a process ID, a description of the process is returned by [GetRunningProcessDescription](#).

Process Options

The process options determine part of the engine's behavior when attached to a user-mode process, including whether or not the debugger engine will automatically attach to

child processes created by the target process and what the engine does with the target processes when it exits. See [DEBUG_PROCESS_XXX](#) for a description of the process options.

The process options can be queried using [GetProcessOptions](#). They can be changed using [AddProcessOptions](#), [RemoveProcessOptions](#), and [SetProcessOptions](#).

Disconnecting from Processes

There are three different ways for the engine to disconnect from a process.

1. *Detach*. Resume all the threads in the process so that it will continue running, no longer being debugged. [DetachCurrentProcess](#) will detach the engine from the current process and [DetachProcesses](#) will detach the engine from all processes. Not all targets support detaching. The [Request](#) operation [DEBUG REQUEST TARGET CAN DETACH](#) can be used to check if the target supports detaching.
2. *Terminate*. Attempt to kill the process. [TerminateCurrentProcess](#) will terminate the current process and [TerminateProcesses](#) will terminate all processes in the debugger session.
3. *Abandon*. Remove the process from the list of processes being debugged. The operating system will still consider the process as being debugged and it will remain suspended until another debugger attaches to it or it is killed. [AbandonCurrentProcess](#) will abandon the current process.

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

Live Kernel-Mode Targets

To attach the [debugger engine](#) to a target computer for kernel-mode debugging, use the method [AttachKernel](#).

Note The engine doesn't completely attach to the kernel until the [WaitForEvent](#) method has been called. Only after the kernel has generated an event -- for example, the [initial breakpoint](#) -- does it become available in the debugger session. See [Debugging Session and Execution Model](#) for more details.

If the debugger engine is attached to a kernel which is not the local kernel and the connection is not an eXDI connection, the connection options used to find the target computer can be queried using [GetKernelConnectionOptions](#). The connection can also be re-synchronized or the connection speed changed using [SetKernelConnectionOptions](#).

The debugger can attach to the local kernel, but only in a limited way and only if the computer was booted with the `/debug` boot switch. (In some Windows installations, local kernel debugging is supported when other switches are used, such as `/debugport`, but this is not a guaranteed feature of Windows and should not be relied on.) [IsKernelDebuggerEnabled](#) is used to determine if the local computer is available for debugging. For more information about kernel debugging on a single machine, see [Performing Local Kernel Debugging](#).

Dump-File Targets

For an introduction and overview of crash dump files, see [Crash Dump Files](#).

Opening Dump Files

To open a crash dump file for use as a debugger target, use [OpenDumpFile](#) or [OpenDumpfileWide](#). These methods are similar to the [.opendump](#) debugger command.

Note The engine doesn't completely attach to the dump file until the [WaitForEvent](#) method has been called. When a dump file is created from a process or kernel, information about the last event is stored in the dump file. After the dump file is opened, the next time execution is attempted, the engine will generate this event for the event callbacks. Only then does the dump file become available in the debugging session. See [Debugging Session and Execution Model](#) for more details.

Additional files can be used to assist in debugging a crash dump file. The methods [AddDumpInformationFile](#) and [AddDumpInformationFileWide](#) register files containing page-file information to be used when the next dump file is opened. These methods must be called before the dump file is opened. [GetNumberDumpFiles](#) will return the number of such files that were used when the current dump file was opened and [GetDumpFile](#) will return a description of these files.

User-mode minidump files contain several streams of information. These streams can be read using the [Request](#) operation [DEBUG REQUEST READ USER MINIDUMP STREAM](#).

Creating Dump Files

To create a crash dump file of the current target -- user-mode or kernel-mode -- use [WriteDumpFile2](#). This method is similar to the [.dump](#) debugger command.

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

Remote Targets

There are two different forms of remote debugging, depending on which computer (remote client or server) is the host computer. The *host computer* is the computer on which the [debugger engine](#) is active. On the other computer, the debugger engine is merely acting as a proxy relaying commands and data to the host engine.

All debugger operations -- such as executing commands and [extensions](#), and symbol loading -- are performed by the host engine. A debugger session is also relative to the host engine.

To list the debugging servers and process servers currently running on a computer, use [OutputServers](#).

Debugging Servers and Debugging Clients

A *debugging server* is an instance of the debugger engine acting as a host and listening for connections from debugging clients. The method [StartServer](#) will tell the debugger engine to start listening for connections from debugging clients.

A *debugging client* is an instance of the debugger engine acting as a proxy, sending debugger commands and I/O to the debugging server. The function [DebugConnect](#) can be used to connect to the debugging server.

The client object returned by [DebugConnect](#) is not automatically joined to the debugger session on the debugging server. The method [ConnectSession](#) can be used to join the session, synchronizing input and output.

The communication between a debugging server and a debugging client mostly consists of debugger commands and RPC calls sent to the server, and command output sent back to the client.

Process Servers, Kernel Connection Servers, and Smart Clients

Process servers and *kernel connection servers* are both instances of the debugger engine acting as proxies, listening for connections from smart clients, and performing memory, processor, or operating system operations as requested by these remote clients. A *process server* facilitates the debugging of processes that are running on the same computer. A *kernel connection server* facilitates the debugging of a Windows kernel debugging target that is connected to the computer that is running the connection server. A process server can be started using the method [StartProcessServer](#) or the program [DbgSrv](#). The method [WaitForProcessServerEnd](#) will wait for a process server started with [StartProcessServer](#) to end. A kernel connection server can be activated using the program [KdSrv](#).

A *smart client* is an instance of the debugger engine acting as a host engine and connected to a process server. The method [ConnectProcessServer](#) will connect to a process server. Once connected, the methods described in [Live User-Mode Targets](#) can be used.

When the remote client is finished with the process server, it can disconnect using [DisconnectProcessServer](#), or it can use [EndProcessServer](#) to request that the process server shut down. To shut down the process server from the computer that it is running on, use Task Manager to end the process. If the instance of the debugger engine that used [StartProcessServer](#) is still running, it can use [Execute](#) to issue the debugger command [.endsrv 0](#), which will end the process server (this is an exception to the usual behavior of [.endsrv](#), which generally does not affect process servers).

The communication between a process server and a smart client typically consists of low-level memory, processor, and operating system operations and requests that are sent from the remote client to the server. Their results are then sent back to the client.

[Send comments about this topic to Microsoft](#)

Target Information

The method [GetDebuggeeType](#) returns the nature of the current target (for example, whether it is a kernel-mode or user-mode target), and how the [debugger engine](#) is connected to it.

If the target is a crash dump file file, the method [GetDumpFormatFlags](#) will indicate what information is contained in the dump.

Target's Computer

The page size of the target's computer is returned by [GetPageSize](#). [IsPointer64Bit](#) will indicate if the computer uses 32-bit or 64-bit addresses.

Note Internally, the debugger engine always uses 64-bit addresses for the target. If the target only uses 32-bit addresses, the engine automatically converts them when communicating with the target.

The number of processors in the target's computer is returned by [GetNumberProcessors](#).

There are three different processor types associated with the target's computer:

- The *actual processor type* is the type of the physical processor in the target's computer. This is returned by [GetActualProcessorType](#).
- The *executing processor type* is the type of the processor used in the currently executing processor context. This is returned by [GetExecutingProcessorType](#).
- The *effective processor type* is the processor type the debugger uses when interpreting information from the target -- for example, setting breakpoints, accessing registers, and getting stack traces. The effective processor type is returned by [GetEffectiveProcessorType](#) and can be changed using [SetEffectiveProcessorType](#).

The effective processor type and executing processor type may differ from the actual processor type -- for example, when the physical processor is an x64 processor and it is running in x86 mode.

The different executing processor types that are supported by the physical processor on the target's computer are returned by [GetPossibleExecutingProcessorTypes](#). The number of these is returned by [GetNumberPossibleExecutingProcessorTypes](#).

The list of processor types that is supported by the debugger engine is returned by [GetSupportedProcessorTypes](#). The number of supported processor types is returned by [GetNumberSupportedProcessorTypes](#).

The names (full and abbreviated) of a processor type are returned by [GetProcessorTypeNames](#).

The current time on the target's computer is returned by [GetCurrentTimeDate](#). The length of time the target's computer has been running since the last boot is returned by [GetCurrentSystemUpTime](#). Time information may not be available for all targets.

Target Versions

The Windows version running on the target's computer is returned by [GetSystemVersionValues](#) and the [Request](#) operation [DEBUG REQUEST GET WIN32 MAJOR MINOR VERSIONS](#), and a description of the Windows version is returned by [GetSystemVersionString](#). Some of this information is also returned by [GetSystemVersion](#).

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

Target State

The method [OutputCurrentState](#) will print the current state of the target to the debugger's output stream.

The current execution status of the target is returned by [GetExecutionStatus](#). If the target is suspended, the method [SetExecutionStatus](#) can be used to resume execution in one of the execution modes.

The method [GetReturnOffset](#) returns the address of the instruction that will execute when the current function returns.

[GetNearInstruction](#) returns the location of an instruction relative to a given address.

Examining the Stack Trace

A *call stack* contains the data for the function calls that are made by a thread. The data for each function call is called a *stack frame* and includes the return address, parameters passed to the function, and the function's local variables. Each time a function call is made, a new stack frame is pushed onto the top of the stack. When that function returns, the stack frame is popped off the stack. Each thread has its own call stack, which represents the calls that are made in that thread.

Note Not all of the data for a function call can be stored in the stack frame. Parameters and local variables, at times, can be stored in registers.

To retrieve the call stack or *stack trace*, use the methods [GetStackTrace](#) and [GetContextStackTrace](#). The stack trace can be printed using [OutputStackTrace](#) and [OutputContextStackTrace](#).

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

Calling Extensions and Extension Functions

To load an extension library (or to obtain a handle for an already loaded extension library), use [AddExtension](#). An extension library can be unloaded with [RemoveExtension](#).

Extension commands can be called using [CallExtension](#).

Extension Functions

Extension functions are functions that are exported by extension libraries. They can use any function prototype and are called directly using C function pointers.

They are not extension commands and are not available via debugger commands. Extension functions cannot be called remotely; they must be called directly. Hence they cannot be used from debugging clients. They can only be called when the client object is inside the host engine - when not remotely debugging or when using a smart client.

Extension functions are identified within extension libraries by the "_EFN_" prepended to their names.

To obtain a pointer to an extension function, use [GetExtensionFunction](#). The type of this function pointer should match the prototype of the extension function. The extension function can now be called just like any other function pointer in C.

Example

If the following extension function was included in an extension library and loaded into the debugger engine:

```
HRESULT CALLBACK  
_EFN_GetObject(IDebugClient * client, SomeObject * obj);
```

It could be called using:

```
typedef ULONG (CALLBACK * GET_OBJECT)(IDebugClient * client, SomeObject * obj);

HRESULT status = S_OK;
GET_OBJECT extFn = NULL;
SomeObject myObj;

if (g_DebugControl->
    GetExtensionFunction(0,
        "GetObject",
        (FARPROC *) &extFn) == S_OK &&
    extFn)
{
    status = (*extFn)(client, &myObj);
}
```

Assembling and Disassembling Instructions

The debugger engine supports the use of assembly language for displaying and changing code in the target. For an overview of the use of assembly language in the debugger, see [Debugging in Assembly Mode](#).

Note Assembly language is not supported for all architectures. And on some architectures not all instructions are supported.

To assemble a single assembly-language instruction and place the resulting processor instruction in the target's memory, use [Assemble](#).

To disassemble a single instruction by taking a processor instruction from the target and producing a string that represents the assembly instruction, use [Disassemble](#).

The method [GetDisassembleEffectiveOffset](#) returns the first effective address of the last instruction to be disassembled. For example, if the last instruction to be disassembled is `move ax, [ebp+4]`, the effective address is the value of `ebp+4`. This corresponds to the `$ea` pseudo-register.

To send disassembled instructions to the output callbacks, use the methods [OutputDisassembly](#) and [OutputDisassemblyLines](#).

The debugger engine has some options that control the assembly and disassembly. These options are returned by [GetAssemblyOptions](#). They can be set using [SetAssemblyOptions](#) and some options can be turned on with [AddAssemblyOptions](#) or turned off with [RemoveAssemblyOptions](#).

Client Functions

This section includes:

[DebugConnect](#)
[DebugConnectWide](#)
[DebugCreate](#)
[DebugCreateEx](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

DebugConnect function

The **DebugConnect** and **DebugConnectWide** functions create a new client object and return an interface pointer to it. The client object will be connected to a remote host.

Syntax

```
C++  
HRESULT DebugConnect(  
    _In_     PCSTR  RemoteOptions,  
    _In_     REFIID InterfaceId,  
    _Out_    PVOID   *Interface  
) ;
```

Parameters

RemoteOptions [in]

Specifies how the debugger engine will connect to the remote host. These are the same options that get passed to the **-remote** option on the command line. For details on the syntax of this string, see [Activating a Debugging Client](#).

InterfaceId [in]

Specifies the interface identifier (IID) of the desired debugger engine client interface. This is the type of the interface that will be returned in *Interface*. For information about the interface identifier, see [Using Client Objects](#).

Interface [out]

Receives an interface pointer for the new client. The type of this interface is specified by *InterfaceId*.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

As with **IUnknown::QueryInterface**, when the returned interface is no longer needed, its **IUnknown::Release** method should be called.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

[Client Objects](#)

Process Server and Smart Client

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

DebugConnectWide function

The [DebugConnect](#) and [DebugConnectWide](#) functions create a new [client object](#) and return an interface pointer to it. The client object will be connected to a remote host.

Syntax

```
C++
HRESULT DebugConnectWide(
    _In_     PCSTR  RemoteOptions,
    _In_     REFIID InterfaceId,
    _Out_    PVOID   *Interface
);
```

Parameters

RemoteOptions [in]

Specifies how the debugger engine will connect to the remote host. These are the same options that get passed to the **-remote** option on the command line. For details on the syntax of this string, see [Activating a Debugging Client](#).

InterfaceId [in]

Specifies the interface identifier (IID) of the desired debugger engine client interface. This is the type of the interface that will be returned in *Interface*. For information about the interface identifier, see [Using Client Objects](#).

Interface [out]

Receives an interface pointer for the new client. The type of this interface is specified by *InterfaceId*.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

As with **IUnknown::QueryInterface**, when the returned interface is no longer needed, its **IUnknown::Release** method should be called.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

[Client Functions](#)
[Client Objects](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

DebugCreate function

The [DebugCreate](#) function creates a new client object and returns an interface pointer to it.

Syntax

```
C++
HRESULT DebugCreate(
    _In_     REFIID InterfaceId,
    _Out_    PVOID   *Interface
);
```

Parameters

InterfaceId [in]

Specifies the interface identifier (IID) of the desired debugger engine client interface. This is the type of the interface that will be returned in *Interface*. For information

about the interface identifier, see [Using Client Objects](#).

Interface [out]

Receives an interface pointer for the new client. The type of this interface is specified by *InterfaceId*.

Return value

This method may also return other error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The function was successful.
E_NOINTERFACE	The client object doesn't implement the specified interface.

Remarks

The parameters passed to **DebugCreate** are the same as those passed to **IUnknown::QueryInterface**, and they are treated the same way.

As with **IUnknown::QueryInterface**, when the returned interface is no longer needed, its **IUnknown::Release** method should be called.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

[Client Objects](#)

DebugCreateEx function

The **DebugCreateEx** function creates a new [client object](#) and returns an interface pointer to it.

Syntax

C++

```
HRESULT DebugCreateEx(
    _In_ REFIID InterfaceId,
    _In_ DWORD DbgEngOptions,
    _Out_ PVOID *Interface
);
```

Parameters

InterfaceId [in]

Specifies the interface identifier (IID) of the desired debugger engine client interface. This is the type of the interface that will be returned in *Interface*. For information about the interface identifier, see [Using Client Objects](#).

DbgEngOptions [in]

Supplies debugger option flags.

Interface [out]

Receives an interface pointer for the new client. The type of this interface is specified by *InterfaceId*.

Return value

This method may also return other error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The function was successful.
E_NOINTERFACE	The client object doesn't implement the specified interface.

Remarks

The parameters passed to **DebugCreateEx** are the same as those passed to **IUnknown::QueryInterface**, and they are treated the same way.

As with **IUnknown::QueryInterface**, when the returned interface is no longer needed, its **IUnknown::Release** method should be called.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugAdvanced interface

Members

The **IDebugAdvanced** interface inherits from the **IUnknown** interface. **IDebugAdvanced** also has these types of members:

- [Methods](#)

Methods

The **IDebugAdvanced** interface has these methods.

Method	Description
GetThreadContext	Returns the current thread context.
SetThreadContext	Sets the current thread context.

Requirements

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugAdvanced2](#)
[IDebugAdvanced3](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugAdvanced::GetThreadContext method

The **GetThreadContext** method returns the current [thread context](#).

Syntax

```
C++
HRESULT GetThreadContext(
    [out] PVOID Context,
    [in]   ULONG ContextSize
);
```

Parameters

Context [out]

Receives the current thread context. The type of the thread context is the CONTEXT structure for the target's effective processor. The buffer *Context* must be large enough to hold this structure.

ContextSize [in]

Specifies the size of the buffer *Context*.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

For more information about the thread context, see [Scopes and Symbol Groups](#).

Note The CONTEXT structure varies with operating system and platform. Care should be taken when using the CONTEXT structure.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h or Ntddk.h)

See also

IDebugAdvanced::SetThreadContext method

The **SetThreadContext** method sets the current [thread context](#).

Syntax

```
C++  
HRESULT SetThreadContext(  
    [in] PVOID Context,  
    [in] ULONG ContextSize  
) ;
```

Parameters

Context [in]

Specifies the thread context. The type of the thread context is the CONTEXT structure for the target's effective processor. The buffer *Context* must be large enough to hold this structure.

ContextSize [in]

Specifies the size of the buffer *Context*.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

For more information about the thread context, see [Scopes and Symbol Groups](#).

Note The CONTEXT structure varies with operating system and platform. Care should be taken when using the CONTEXT structure.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugAdvanced2 interface

Members

The IDebugAdvanced2 interface inherits from [IDebugAdvanced](#). IDebugAdvanced2 also has these types of members:

- [Methods](#)

Methods

The IDebugAdvanced2 interface has these methods.

Method	Description
FindSourceFileAndToken	Returns the filename of a source file on the source path or return the value of a variable associated with a file token.
GetSourceFileInfo	Returns specified information about a source file.
GetSymbolInfo	Returns specified information about a symbol.
GetSystemObjectInfo	Returns information about operating system objects on the target.
Request	Performs a variety of different operations.

Requirements

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugAdvanced](#)
[IDebugAdvanced3](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugAdvanced2::FindSourceFileAndToken method

The **FindSourceFileAndToken** method returns the filename of a source file on the source path or return the value of a variable associated with a file token.

Syntax

```
C++  
HRESULT FindSourceFileAndToken(  
    [in]           ULONG   StartElement,  
    [in]           ULONG64 ModAddr,  
    [in]           PCSTR   File,  
    [in]           ULONG   Flags,  
    [in, optional] PVOID   FileToken,  
    [in]           ULONG   FileTokenSize,  
    [out, optional] PULONG  FoundElement,  
    [out, optional] PSTR    Buffer,  
    [in]           ULONG   BufferSize,  
    [out, optional] PULONG  FoundSize  
) ;
```

Parameters

StartElement [in]

Specifies the index of an element within the source path to start searching from. All elements in the source path before *StartElement* are excluded from the search. The index of the first element is zero. If *StartElement* is greater than or equal to the number of elements in the source path, the filing system is checked directly.

This parameter can be used with *FoundElement* to check for multiple matches in the source path.

StartElement is ignored if the flag DEBUG_FIND_SOURCE_TOKEN_LOOKUP is set in *Flags*.

ModAddr [in]

Specifies a location within the memory allocation of the module in the target to which the source file is related. *ModAddr* is used for caching the search results and when querying source servers for the file. *ModAddr* can be **NULL**.

ModAddr is ignored if the flag DEBUG_FIND_SOURCE_TOKEN_LOOKUP is set in *Flags*. And it is not used for querying source servers if *FileToken* is not **NULL**.

File [in]

Specifies the path and filename of the file to search for.

If the flag DEBUG_FIND_SOURCE_TOKEN_LOOKUP is set, the file is already specified by the token in *FileToken*. In this case, *File* specifies the name of a variable on the source server related to the file. The variable must begin and end with the percent sign (%), for example, %SRCRVCMD%. The value of this variable is returned.

Flags [in]

Specifies the flags that control the behavior of this method. For a description of these flags, see [DEBUG_FIND_SOURCE_XXX](#).

FileToken [in, optional]

Specifies a file token representing a file on a source server. A file token can be obtained by setting *Which* to DEBUG_SRCFILE_SYMBOL_TOKEN in the method [GetSourceFileInfo](#).

If the flag DEBUG_FIND_SOURCE_TOKEN_LOOKUP is set, *FileToken* must not be **NULL**.

FileTokenSize [in]

Specifies the size in bytes of the *FileToken* token. If *FileToken* is **NULL**, this parameter is ignored.

FoundElement [out, optional]

Receives the index of the element within the source path that contained the file. If the file was found directly on the filing system (not using the source path), -1 is returned to *FoundElement*. If *FoundElement* is **NULL** or *Flags* contain DEBUG_SRCFILE_SYMBOL_TOKEN, this information is not returned.

Buffer [out, optional]

Receives the name of the file that was found. If the file is not on a source server, this is the name of the file in the local source cache. If the flag DEBUG_FIND_SOURCE_FULL_PATH is set, this is the full canonical path name for the file. Otherwise, it is the concatenation of the directory in the source path with the tail of *File* that was used to find the file.

If the flag DEBUG_SRCFILE_SYMBOL_TOKEN is set in *Flags*, *Buffer* receives the value of the variable named *File* associated with the file token *FileToken*.

If *Buffer* is **NULL**, this information is not returned.

BufferSize [in]

Specifies the size in characters of the *Buffer* buffer. If *Buffer* is **NULL**, this parameter is ignored.

FoundSize [out, optional]

Specifies the size in characters of the name of the file. If *foundSize* is **NULL**, this information is not returned.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
S_FALSE	The method was successful. However, the <i>Buffer</i> buffer was too small to hold the file name or variable value, so the string was truncated to fit in the buffer.

Remarks

When the flag DEBUG_SRCFILE_SYMBOL_TOKEN is set in *Flags*, this method does not search for a file on the source path. Instead, it looks up a variable associated with the file token provided in *FileToken*. These variables are documented in the topic [Language Specification 1](#). For example, to retrieve the value of the variable SRCSRVCMD--the command to extract the source file from source control (also returned by the DEBUG_SRCFILE_SYMBOL_TOKEN_SOURCE_COMMAND_WIDE function of [GetSourceFileInfo](#))--set *File* to %SRCRVCMD%.

The engine uses the following steps--in order--to search for the file:

1. If the source path contains any source servers and the flag DEBUG_FIND_SOURCE_NO_SRCSRV is not set, the source server in the source path is searched first.
The first match found is returned.
2. For each directory in the source path, an attempt is made to find an overlap between the end of the directory path and the beginning of the file path. For example, if the

source path contains a directory C:\a\b\c\d and *File* is c\d\e\foo.c, the file C:\a\b\c\d\e\foo.c is a match.

If the flag DEBUG_FIND_SOURCE_BEST_MATCH is set, the match with the longest overlap is returned; otherwise, the first match is returned.

3. For each directory in the source path, *File* is appended to the directory. If no match is found, this process is repeated and each time the first directory is removed from the beginning of the file path. For example, if the source path contains a directory C:\a\b and *File* is c\d\e\foo.c, the file C:\a\b\c\d\e\foo.c is a match.

The first match found is returned.

4. The file *File* is looked up directly on the filing system.

For more information about source files, see [Using Source Files](#). For an overview of the source path and its syntax, see [Source Path](#).

IDebugAdvanced2::GetSourceFileInfo method

The **GetSourceFileInfo** method returns specified information about a source file.

Syntax

```
C++
HRESULT GetSourceFileInfo(
    [in]           ULONG   Which,
    [in]           PSTR    SourceFile,
    [in]           ULONG64 Arg64,
    [in]           ULONG   Arg32,
    [out, optional] PVOID   Buffer,
    [in]           ULONG   BufferSize,
    [out, optional] PULONG  InfoSize
);
```

Parameters

Which [in]

Specifies the piece of information to return. The *Which* parameter can take one of the values in the following table.

DEBUG_SRCFILE_SYMBOL_TOKEN

Returns a token representing the specified source file on a source server. This token can be passed to [FindSourceFileAndToken](#) to retrieve information about the file. The token is returned to the *Buffer* buffer as an array of bytes. The size of this token is a reflection of the size of the SrcSrv token.

DEBUG_SRCFILE_SYMBOL_TOKEN_SOURCE_COMMAND_WIDE

Queries a source server for the command to extract the source file from source control. This includes the name of the executable file and its command-line parameters. The command is returned to the *Buffer* buffer as a Unicode string.

SourceFile [in]

Specifies the source file whose information is being requested. The source file is looked up on all the source servers in the source path.

Arg64 [in]

Specifies a 64-bit argument. The value of *Which* specifies the module whose symbol token is requested. Regardless of the value of *Which*, *Arg64* is a location within the memory allocation of the module.

Arg32 [in]

Specifies a 32-bit argument. This parameter is currently unused.

Buffer [out, optional]

Receives the requested symbol information. The type of the data returned depends on the value of *Which*. If *Buffer* is **NULL**, this information is not returned.

BufferSize [in]

Specifies the size in bytes of the *Buffer* buffer. If *Buffer* is **NULL**, *BufferSize* must also be **NULL**.

InfoSize [out, optional]

Specifies the size in bytes of the information returned to the *Buffer* buffer. This parameter can be **NULL** if the data is not required.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
S_FALSE	The method was successful. However, the information would not fit in the <i>Buffer</i> buffer, so the information or name was truncated.

Remarks

For more information about source files, see [Using Source Files](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

IDebugAdvanced2::GetSymbolInformation method

The **GetSymbolInformation** method returns specified information about a symbol.

Syntax

```
C++
HRESULT GetSymbolInformation(
    [in]           ULONG   Which,
    [in]           ULONG64 Arg64,
    [in]           ULONG   Arg32,
    [out, optional] PVOID   Buffer,
    [in]           ULONG   BufferSize,
    [out, optional] PULONG  InfoSize,
    [out, optional] PSTR    StringBuffer,
    [in]           ULONG   StringBufferSize,
    [out, optional] PULONG  StringSize
);
```

Parameters

Which [in]

Specifies the piece of information to return. *Which* can take one of the values in the follow table.

Value	Information returned
DEBUG_SYMBOL_BREAKPOINT_SOURCE_LINE	Returns the source code file name and line number for a specified breakpoint. The line number is returned to <i>Buffer</i> as a ULONG. The file name is returned to <i>StringBuffer</i> .
DEBUG_SYMBOL_IMAGEHELP_MODULEW64	Returns an IMAGEHELP_MODULEW64 structure that describes a specified module. For details about this structure, see the IMAGEHELP_MODULE64 topic in the Debug Help Library documentation (dbghelp.chm).

	No string is returned and <i>StringBuffer</i> , <i>StringBufferSize</i> , and <i>StringSize</i> must all be set to zero.
DEBUG_SYMINFO_GET_SYMBOL_NAME_BY_OFFSET_AND_TAG_WIDE	Returns the Unicode name of the symbol specified by location in memory and PDB tag type. The name is returned to <i>Buffer</i> . <i>StringBuffer</i> is not used.
DEBUG_SYMINFO_GET_MODULE_SYMBOL_NAMES_AND_OFFSETS	Returns a list of symbol names and offsets for the symbols in the specified module with the specified PDB tag type. The offsets are returned as an array of ULONG values to <i>Buffer</i> . The names are returned in the same order as the offsets to <i>StringBuffer</i> . Some names might contain embedded zeros because annotations can have multi-part names; hence, each name is terminated with two null characters.

Arg64 [in]

Specifies a 64-bit argument. This parameter has the following interpretations depending on the value of *Which*:

DEBUG_SYMINFO_BREAKPOINT_SOURCE_LINE

Ignored.

DEBUG_SYMINFO_IMAGEHELP_MODULEW64

The base address of the module whose description is being requested.

DEBUG_SYMINFO_GET_SYMBOL_NAME_BY_OFFSET_AND_TAG_WIDE

Specifies the address in the target's memory of the symbol whose name is being requested.

DEBUG_SYMINFO_GET_MODULE_SYMBOL_NAMES_AND_OFFSETS

Specifies the module whose symbols are requested. *Arg64* is a location within the memory allocation of the module.

Arg32 [in]

Specifies a 32-bit argument. This parameter has the following interpretations depending on the value of *Which*:

DEBUG_SYMINFO_BREAKPOINT_SOURCE_LINE

The engine breakpoint ID of the desired breakpoint.

DEBUG_SYMINFO_IMAGEHELP_MODULEW64

Set to zero.

DEBUG_SYMINFO_GET_SYMBOL_NAME_BY_OFFSET_AND_TAG_WIDE

The PDB classification of the symbol. *Arg32* must be one of the values in the **SymTagEnum** enumeration defined in Dbghelp.h. For more information, see PDB documentation.

DEBUG_SYMINFO_GET_MODULE_SYMBOL_NAMES_AND_OFFSETS

The PDB classification of the symbol. *Arg32* must be one of the values in the **SymTagEnum** enumeration defined in Dbghelp.h. For more information, see PDB documentation.

Buffer [out, optional]

Receives the requested symbol information. The type of the data returned depends on the value of *Which*. If *Buffer* is **NULL**, this information is not returned.

BufferSize [in]

Specifies the size, in bytes, of the buffer *Buffer*.

InfoSize [out, optional]

If this method returns **S_OK**, *InfoSize* receives the size, in bytes, of the symbol information returned to *Buffer*. If this method returns **S_FALSE**, the supplied buffer is not big enough, and *InfoSize* receives the required buffer size. If *InfoSize* is **NULL**, this information is not returned.

StringBuffer [out, optional]

Receives the requested string. The interpretation of this string depends on the value of *Which*. If *StringBuffer* is **NULL**, this information is not returned.

StringBufferSize [in]

Specifies the size, in characters, of the string buffer *StringBuffer*.

StringSize [out, optional]

Receives the size, in characters, of the string returned to *StringBuffer*. If *StringSize* is **NULL**, this information is not returned.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
S_FALSE	The method was successful. However, the information would not fit in the buffer <i>Buffer</i> or the string would not fit in the buffer <i>StringBuffer</i> , so the information or name was truncated.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugAdvanced2::GetSystemObjectInformation method

The **GetSystemObjectInformation** method returns information about operating system objects on the target.

Syntax

```
C++
HRESULT GetSystemObjectInformation(
    [in]           ULONG      Which,
    [in]           ULONG64    Arg64,
    [in]           ULONG      Arg32,
    [out, optional] PVOID     Buffer,
    [in]           ULONG      BufferSize,
    [out, optional] PULONG    InfoSize
);
```

Parameters

Which [in]

Specifies the type of object and the type of information to return about that object. *Which* can take the following value.

Value	Information returned
DEBUG_SYSOBJINFO_THREAD_BASIC_INFORMATION	Returns details of the thread specified by engine thread ID.

Arg64 [in]

Specifies a 64-bit argument. This parameter has the following interpretations depending on the value of *Which*:

DEBUG_SYSOBJINFO_THREAD_BASIC_INFORMATION

Not used.

Arg32 [in]

Specifies a 32-bit argument. This parameter has the following interpretations depending on the value of *Which*:

DEBUG_SYSOBJINFO_THREAD_BASIC_INFORMATION

The engine thread ID of the desired thread.

Buffer [out, optional]

Receives the requested information. The type of data returned in *Buffer* depends on the value of *Which*.

Value	Return type
DEBUG_SYSOBJINFO_THREAD_BASIC_INFORMATION	DEBUG_THREAD_BASIC_INFORMATION

BufferSize [in]

Specifies the size, in bytes, of the buffer *Buffer*.

InfoSize [out, optional]

Receives the size of the information that is returned.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
S_FALSE	The method was successful. However, the information would not fit in the buffer <i>Buffer</i> , so the information was truncated.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugAdvanced2::Request method

The **Request** method performs a variety of different operations.

Syntax

C++

```
HRESULT Request(
    [in]           ULONG   Request,
    [in, optional] PVOID   InBuffer,
    [in]           ULONG   InBufferSize,
    [out, optional] PVOID   OutBuffer,
    [in]           ULONG   OutBufferSize,
    [out, optional] PULONG  OutSize
);
```

Parameters

Request [in]

Specifies which operation to perform. **Request** can be one of the values in the following table. Details of each operation can be found by following the link in the "Request" column.

Request	Action
DEBUG REQUEST SOURCE PATH HAS SOURCE SERVER	Check the source path for a source server.
DEBUG REQUEST TARGET EXCEPTION CONTEXT	Return the thread context for the stored event in a user-mode minidump file.
DEBUG REQUEST TARGET EXCEPTION THREAD	Return the operating system thread ID for the stored event in a user-mode minidump file.
DEBUG REQUEST TARGET EXCEPTION RECORD	Return the exception record for the stored event in a user-mode minidump file.
DEBUG REQUEST GET ADDITIONAL CREATE OPTIONS	Return the default process creation options.
DEBUG REQUEST SET ADDITIONAL CREATE OPTIONS	Set the default process creation options.
DEBUG REQUEST GET WIN32 MAJOR MINOR VERSIONS	Return the version of Windows that is currently running on the target.
DEBUG REQUEST READ USER MINIDUMP STREAM	Read a stream from a user-mode minidump target.
DEBUG REQUEST TARGET CAN DETACH	Check to see if it is possible for the debugger engine to detach from the current process (leaving the process running but no longer being debugged).
DEBUG REQUEST SET LOCAL IMPLICIT COMMAND LINE	Set the debugger engine 's implicit command line.
DEBUG REQUEST GET CAPTURED EVENT CODE OFFSET	Return the current event's instruction pointer.
DEBUG REQUEST READ CAPTURED EVENT CODE STREAM	Return up to 64 bytes of memory at the current event's instruction pointer.
DEBUG REQUEST EXT TYPED DATA ANSI	Perform a variety of different operations that aid in the interpretation of typed data.

InBuffer [in, optional]

Specifies the input to this method. The type and interpretation of the input depends on the *Request* parameter.

InBufferSize [in]

Specifies the size of the input buffer *InBuffer*. If the request requires no input, *InBufferSize* should be set to zero.

OutBuffer [out, optional]

Receives the output from this method. The type and interpretation of the output depends on the *Request* parameter. If *OutBuffer* is **NULL**, the output is not returned.

OutBufferSize [in]

Specifies the size of the output buffer *OutBufferSize*. If the type of the output returned to *OutBuffer* has a known size, *OutBufferSize* is usually expected to be exactly that size, even if *OutBuffer* is set to **NULL**.

OutSize [out, optional]

Receives the size of the output returned in the output buffer *OutBuffer*. If *OutSize* is **NULL**, this information is not returned.

Return value

The interpretation of the return value depends on the value of the *Request* parameter. Unless otherwise stated, the following values may be returned.

Return code	Description
S_OK	The method was successful.
S_FALSE	The method was successful. However, the output would not fit in the output buffer <i>OutBuffer</i> , so truncated output was returned.
E_INVALIDARG	The size of the input buffer <i>InBufferSize</i> or the size of the output buffer <i>OutBufferSize</i> was not the expected value.

This method may also return error values. See [Return Values](#) for more details.

Requirements

DEBUG_REQUEST_SOURCE_PATH_HAS_SOURCE_SERVER

The DEBUG_REQUEST_SOURCE_PATH_HAS_SOURCE_SERVER [Request](#) operation checks the source path for a source server.

Parameters

InBuffer

Not used.

OutBuffer

Not used.

Return Value

S_OK

The source path includes a source server

S_FALSE

The source path does not include a source server.

© 2016 Microsoft. All rights reserved.

DEBUG_REQUEST_TARGET_EXCEPTION_CONTEXT

The DEBUG_REQUEST_TARGET_EXCEPTION_CONTEXT [Request](#) operation returns the [thread context](#) for the stored event in a user-mode minidump file.

Parameters

InBuffer

Not used.

OutBuffer

The thread context for the stored event. The type of the thread context is the CONTEXT structure for the target's effective processor at the time of the event. *OutBuffer* must be large enough to hold this structure.

Remarks

This information is also returned to the *Context* parameter by the [GetStoredEventInformation](#) method.

DEBUG_REQUEST_TARGET_EXCEPTION_RECORD

The DEBUG_REQUEST_TARGET_EXCEPTION_RECORD [Request](#) operation returns the exception record for the stored event in a user-mode minidump file.

InBuffer

Not used.

OutBuffer

The exception record for the stored event. The type of the exception record is EXCEPTION_RECORD64, which is defined in winnt.h.

See also[Request](#)

DEBUG_REQUEST_GET_ADDITIONAL_CREATE_OPTIONS control code

The DEBUG_REQUEST_GET_ADDITIONAL_CREATE_OPTIONS [Request](#) operation returns the default process creation options.

Parameters*InBuffer*

Not used.

OutBuffer

The default process creation options. The type of the process creation options is [DEBUG_CREATE_PROCESS_OPTIONS](#).

Remarks

The default process creation options are used by methods [CreateProcess](#) and [CreateProcessAndAttach](#) which, unlike [CreateProcess2](#) and [CreateProcessAndAttach2](#), do not specify the full range of process creation options.

The [CreateFlags](#) field of the [DEBUG_CREATE_PROCESS_OPTIONS](#) structure is not used as a default because all process creation operations provide this information.

DEBUG_REQUEST_SET_ADDITIONAL_CREATE_OPTIONS

The DEBUG_REQUEST_SET_ADDITIONAL_CREATE_OPTIONS [Request](#) operation sets the default process creation options.

Parameters*InBuffer*

The new default process creation options. The type of the process creation options is [DEBUG_CREATE_PROCESS_OPTIONS](#).

OutBuffer

Not used.

Remarks

The default process creation options are used by methods [CreateProcess](#) and [CreateProcessAndAttach](#) which, unlike [CreateProcess2](#) and [CreateProcessAndAttach2](#), do not specify the full range of process creation options.

The [CreateFlags](#) field of the [DEBUG_CREATE_PROCESS_OPTIONS](#) structure is not used as a default because all process creation operations provide this information.

DEBUG_REQUEST_GET_WIN32_MAJOR_MINOR_VERSIONS

The DEBUG_REQUEST_GET_WIN32_MAJOR_MINOR_VERSIONS [Request](#) operation returns the version of Windows that is currently running on the target.

Parameters

InBuffer

Not used.

OutBuffer

The major and minor version numbers for the version of Windows that is currently running on the target. The type of the version numbers is an array containing two ULONG values; the first ULONG in the array is the major version number and the second is the minor version number

The following table lists the major and minor version numbers by operating system.

Version of Windows	Major version number	Minor version number
Windows 2000	5	0
Windows XP	5	1
Windows Server 2003	5	2

DEBUG_REQUEST_READ_USER_MINIDUMP_STREAM

The DEBUG_REQUEST_READ_USER_MINIDUMP_STREAM [Request](#) operation reads a stream from a user-mode minidump target.

Parameters

InBuffer

The stream to read and the buffer into which to place the contents of the stream. The type of this parameter is DEBUG_READ_USER_MINIDUMP_STREAM.

OutBuffer

Not used.

The DEBUG_READ_USER_MINIDUMP_STREAM structure holds the parameters for the DEBUG_REQUEST_READ_USER_MINIDUMP_STREAM [Request](#) operation.

C++

```
typedef struct _DEBUG_READ_USER_MINIDUMP_STREAM
{
    IN ULONG StreamType;
    IN ULONG Flags;
    IN ULONG64 Offset;
    OUT PVOID Buffer;
    IN ULONG BufferSize;
    OUT ULONG BufferUsed;
} DEBUG_READ_USER_MINIDUMP_STREAM, *PDEBUG_READ_USER_MINIDUMP_STREAM;
```

Members

StreamType

Specifies the stream to read from the minidump file. The possible values for **StreamType** come from the MINIDUMP_STREAM_TYPE enumeration.

For a list of possible values and their interpretation, see the MINIDUMP_STREAM_TYPE topic in the Debug Help Library documentation in dbghelp.chm.

Flags

Set to zero.

Offset

Specifies the offset within the stream to start reading. To start reading from the beginning of the stream, set **Offset** to zero.

Buffer

Receives the bytes read from the minidump stream. **Buffer** cannot be **NULL**.

BufferSize

Specifies the size, in bytes, of the buffer **Buffer**.

BufferUsed

Receives the number of bytes read into the buffer **Buffer**.

Remarks

The target must be a user-mode minidump file.

Each minidump file contains a number of *streams*. These streams are blocks of data written to the minidump file.

Requirements

Header Dbgeng.h (include Dbgeng.h)

DEBUG_REQUEST_TARGET_CAN_DETACH

The DEBUG_REQUEST_TARGET_CAN_DETACH [Request](#) operation checks to see if it is possible for the debugger engine to detach from the current process (leaving the process running but no longer being debugged).

Parameters

InBuffer

Not used.

OutBuffer

Not used.

Return Value

S_OK

It is possible to detach the debugger from the current process.

S_FALSE

It is not possible to detach the debugger from the current process.

Remarks

Only targets running on Microsoft Windows XP or later versions of Windows support detaching the debugger from the process.

DEBUG_REQUEST_SET_LOCAL_IMPLICIT_COMMAND_LINE

The DEBUG_REQUEST_SET_LOCAL_IMPLICIT_COMMAND_LINE [Request](#) operation sets the [debugger engine](#)'s implicit command line.

Parameters

InBuffer

The new implicit command line. The type of *InBuffer* is a pointer to a Unicode string (PWSTR). The pointer is copied but the string it points to is not copied.

OutBuffer

Not used.

Remarks

The implicit command line can be used as the command line when creating a process. The process creation options ([DEBUG_CREATE_PROCESS_OPTIONS](#)) contain an option for using the implicit command line instead of a supplied command line when creating a process.

DEBUG_REQUEST_GET_CAPTURED_EVENT_CODE_OFFSET

The DEBUG_REQUEST_GET_CAPTURED_EVENT_CODE_OFFSET [Request](#) operation returns the current event's instruction pointer.

Parameters

InBuffer

Not used.

OutBuffer

The instruction pointer of the current event. The type of the instruction pointer is ULONG64.

Return Value

S_OK

The method was successful.

E_NOINTERFACE

The memory at the instruction pointer for the current event is not valid.

This method may also return error values. See [Return Values](#) for more details.

Remarks

The memory at the instruction pointer for the current event can be read using the [Request](#) operation's [DEBUG_REQUEST_READ_CAPTURED_EVENT_CODE_STREAM](#).

See also

[Request](#)
[DEBUG_REQUEST_READ_CAPTURED_EVENT_CODE_STREAM](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

DEBUG_REQUEST_READ_CAPTURED_EVENT_CODE_STREAM

The DEBUG_REQUEST_READ_CAPTURED_EVENT_CODE_STREAM [Request](#) operation returns up to 64 bytes of memory at the current event's instruction pointer.

Parameters

InBuffer

Not used.

OutBuffer

The memory at the current event's instruction pointer. Up to 64 bytes of memory may be returned.

Remarks

The memory returned is a snapshot of the memory taken when the event occurred. It does not reflect any changes that may have been made to the target's memory since the event.

The current event's instruction pointer is returned by the [Request](#) operation [DEBUG_REQUEST_GET_CAPTURED_EVENT_CODE_OFFSET](#).

DEBUG_REQUEST_EXT_TYPED_DATA_ANSI

The DEBUG_REQUEST_EXT_TYPED_DATA_ANSI [Request](#) operation performs a variety of different sub-operations that aid in the interpretation of typed data.

Parameters

InBuffer

Specifies the [EXT_TYPED_DATA](#) structure that determines the sub-operation to perform. This EXT_TYPED_DATA structure contains the input parameters for that sub-operation along with any (optional) additional data. The additional data is included in *InBuffer* after the EXT_TYPED_DATA structure. The size of *InBuffer* is the total size of the buffer that contains the EXT_TYPED_DATA structure and the additional data. See [EXT_TYPED_DATA](#) for details on this structure and how to include the additional data.

The following sub-operations are supported.

Sub-Operation	Description
EXT_TDOP_COPY	Makes a copy of a typed data description.
EXT_TDOP_RELEASE	Releases a typed data description.
EXT_TDOP_SET_FROM_EXPR	Returns the value of an expression.
EXT_TDOP_SET_FROM_U64_EXPR	Returns the value of an expression. An optional address can be provided as a parameter to the expression.
EXT_TDOP_GET_FIELD	Returns a member of a structure.
EXT_TDOP_EVALUATE	Returns the value of an expression. An optional value can be provided as a parameter to the expression.
EXT_TDOP_GET_TYPE_NAME	Returns the type name for typed data.
EXT_TDOP_OUTPUT_TYPE_NAME	Prints the type name for typed data.
EXT_TDOP_OUTPUT_SIMPLE_VALUE	Prints the value of typed data.
EXT_TDOP_OUTPUT_FULL_VALUE	Prints the type and value for typed data.
EXT_TDOP_HAS_FIELD	Determines if a structure contains a specified member.
EXT_TDOP_GET_FIELD_OFFSET	Returns the offset of a member within a structure.
EXT_TDOP_GET_ARRAY_ELEMENT	Returns an element from an array.
EXT_TDOP_GET_DEREFERENCE	Dereferences a pointer, returning the value it points to.

EXT_TDOP_GET_TYPE_SIZE	Returns the size of the specified typed data.
EXT_TDOP_OUTPUT_TYPE_DEFINITION	Prints the definition of the type for the specified typed data.
EXT_TDOP_GET_POINTER_TO	Returns a new typed data description that represents a pointer to specified typed data.
EXT_TDOP_SET_FROM_TYPE_ID_AND_U64	Creates a typed data description from a type and memory location.
EXT_TDOP_SET_PTR_FROM_TYPE_ID_AND_U64	Creates a typed data description that represents a pointer to a specified memory location with specified type.

OutBuffer

Receives the [EXT_TYPED_DATA](#) structure that contains the output parameters and any additional data for the sub-operation. As with *InBuffer*, the size of *OutBuffer* is the total size of the buffer that contains the EXT_TYPED_DATA structure and any additional data.

The DEBUG_REQUEST_EXT_TYPED_DATA_ANSI operation will initially copy *InBuffer* into *OutBuffer* and then modify the contents of *OutBuffer* in place. This means that *OutBuffer* will be populated with the input parameters of the EXT_TYPED_DATA and any additional data that was provided in *InBuffer*. It also means that the size of *OutBuffer* must be at least as big as the size of *InBuffer*.

Return Value

S_OK

The operation was successful.

This method can also return error values. See [Return Values](#) for more details.

The value returned by this operation is also stored in the **Status** member of *OutBuffer*.

Remarks

The sub-operation performed by the DEBUG_REQUEST_EXT_TYPED_DATA_ANSI [Request](#) operation is determined by the **Operation** member of the EXT_TYPED_DATA structure, which takes a value in the [EXT_TDOP](#) enumeration.

EXT_TDOP_COPY

The EXT_TDOP_COPY sub-operation of the [DEBUG REQUEST EXT_TYPED_DATA ANSI Request](#) operation makes a copy of a typed data description.

Parameters

Operation

Set to EXT_TDOP_COPY for this sub-operation.

InData

Specifies the original instance of the [DEBUG_TYPED_DATA](#) structure.

OutData

Receives the copy of the instance of the [DEBUG_TYPED_DATA](#) structure specified by **InData**.

Status

Receives the status code returned by this sub-operation. This is the same as the value returned by [Request](#).

Remarks

EXT_TDOP_COPY is a value in the [EXT_TDOP](#) enumeration.

The parameters for this sub-operation are members of the [EXT_TYPED_DATA](#) structure. The members of EXT_TYPED_DATA that are not listed in the preceding Parameters section are not used by this sub-operation and should be set to zero. The descriptions of the members in the preceding Parameters section specify what the members are used for. For more details on the members, see [EXT_TYPED_DATA](#).

EXT_TDOP_RELEASE

The EXT_TDOP_RELEASE sub-operation of the [DEBUG_REQUEST_EXT_TYPED_DATA_ANSI Request](#) operation releases a typed data description.

Parameters

Operation

Set to EXT_TDOP_RELEASE for this sub-operation.

InData

Specifies the instance of the [DEBUG_TYPED_DATA](#) structure to release.

Status

Receives the status code returned by this sub-operation. This is the same as the value returned by [Request](#).

Remarks

EXT_TDOP_RELEASE is a value in the [EXT_TDOP](#) enumeration.

The parameters for this sub-operation are members of the [EXT_TYPED_DATA](#) structure. The members of EXT_TYPED_DATA that are not listed in the preceding Parameters section are not used by this sub-operation and should be set to zero. The descriptions of the members in the preceding Parameters section specify only the purpose of the members in this particular setting. See [EXT_TYPED_DATA](#) for more details.

EXT_TDOP_SET_FROM_EXPR

The EXT_TDOP_SET_FROM_EXPR sub-operation of the [DEBUG_REQUEST_EXT_TYPED_DATA_ANSI Request](#) operation returns a typed data description that represents the value of an expression.

Parameters

Operation

Set to EXT_TDOP_SET_FROM_EXPR for this sub-operation.

Flags

Specifies the bit flags that describe the target's memory in which the value of the expression resides. See [EXT_TYPED_DATA](#) for details of these flags.

OutData

Receives the [DEBUG_TYPED_DATA](#) structure that represents the value of the expression.

InStrIndex

Specifies the expression to evaluate. This expression is evaluated by the default expression evaluator.

Status

Receives the status code returned by this sub-operation. This is the same as the value returned by [Request](#).

Remarks

EXT_TDOP_SET_FROM_EXPR is a value in the [EXT_TDOP](#) enumeration.

The parameters for this sub-operation are members of the [EXT_TYPED_DATA](#) structure. The members of EXT_TYPED_DATA that are not listed in the preceding Parameters section are not used by this sub-operation and should be set to zero. The descriptions of the members in the preceding Parameters section specify what the members are used for. See [EXT_TYPED_DATA](#) for more details.

EXT_TDOP_SET_FROM_U64_EXPR

The EXT_TDOP_SET_FROM_U64_EXPR sub-operation of the [DEBUG_REQUEST_EXT_TYPED_DATA_ANSI](#) Request operation returns a typed data description that represents the value of an expression.

Operation

Set to EXT_TDOP_SET_FROM_U64_EXPR for this sub-operation.

Flags

Specifies the bit flags that describe the target's memory in which the value of the expression resides. See [EXT_TYPED_DATA](#) for details of these flags.

InData

Specifies optional typed data whose address in the target's memory can be used in the expression specified by InStrIndex. This address is used by the expression as the pseudo-register \$extin.

OutData

Receives the [DEBUG_TYPED_DATA](#) structure that represents the value of the expression.

InStrIndex

Specifies the expression to evaluate. This expression is evaluated by the default expression evaluator.

Status

Receives the status code returned by this sub-operation. This is the same as the value returned by [Request](#).

Remarks

EXT_TDOP_SET_FROM_U64_EXPR is a value in the [EXT_TDOP](#) enumeration.

The parameters for this sub-operation are members of the [EXT_TYPED_DATA](#) structure. The members of EXT_TYPED_DATA that are not listed in the preceding Parameters section are not used by this sub-operation and should be set to zero. The descriptions of the members in the preceding Parameters section specify what the members are used for. See [EXT_TYPED_DATA](#) for more details.

EXT_TDOP_GET_FIELD

The EXT_TDOP_GET_FIELD sub-operation of the [DEBUG_REQUEST_EXT_TYPED_DATA_ANSI](#) Request operation returns typed data description that represents a member of a given structure.

Parameters**Operation**

Set to EXT_TDOP_GET_FIELD for this sub-operation.

InData

Specifies an instance of [DEBUG_TYPED_DATA](#) that describes the structure whose member is desired.

OutData

Receives an instance of [DEBUG_TYPED_DATA](#) for the requested member.

InStrIndex

Specifies the name of the requested member. The name of the member is a dot-separated path and can contain sub-members - for example, **mymember.mysubmember**. Pointers on this dot-separated path will automatically be dereferenced. However, a dot operator (.) should still be used here instead of the usual C pointer dereference operator (>).

Status

Receives the status code returned by this sub-operation. This is the same as the value returned by [Request](#).

Remarks

EXT_TDOP_GET_FIELD is a value in the [EXT_TDOP](#) enumeration.

The parameters for this sub-operation are members of the [EXT_TYPED_DATA](#) structure. The members of EXT_TYPED_DATA that are not listed in the preceding Parameters section are not used by this sub-operation and should be set to zero. The descriptions of the members in the preceding Parameters section specify what the members are used for. See [EXT_TYPED_DATA](#) for more details.

EXT_TDOP_EVALUATE

The EXT_TDOP_EVALUATE sub-operation of the [DEBUG_REQUEST_EXT_TYPED_DATA_ANSI Request](#) operation returns the typed data description that represents the value of an expression.

Parameters**Operation**

Set to EXT_TDOP_EVALUATE for this sub-operation.

Flags

Specifies the bit flags that describe the target's memory in which the value of the expression resides. See [EXT_TYPED_DATA](#) for details of these flags.

InData

Specifies optional typed data whose value can be used in the expression specified by **InStrIndex**. This value is used by the expression as the pseudo-register \$extin.

OutData

Receives the [DEBUG_TYPED_DATA](#) structure that represents the value of the expression.

InStrIndex

Specifies the expression to evaluate. This expression is evaluated by the default expression evaluator.

Status

Receives the status code returned by this sub-operation. This is the same as the value returned by [Request](#).

Remarks

EXT_TDOP_EVALUATE is a value in the [EXT_TDOP](#) enumeration.

The parameters for this sub-operation are members of the [EXT_TYPED_DATA](#) structure. The members of EXT_TYPED_DATA that are not listed in the preceding Parameters section are not used by this sub-operation and should be set to zero. The descriptions of the members in the preceding Parameters section specify what the members are used for. See [EXT_TYPED_DATA](#) for more details.

EXT_TDOP_GET_TYPE_NAME

The EXT_TDOP_GET_TYPE_NAME sub-operation of the [DEBUG_REQUEST_EXT_TYPED_DATA_ANSI Request](#) operation returns the type name of the specified typed data.

Parameters

Operation

Set to EXT_TDOP_GET_TYPE_NAME for this sub-operation.

InData

Specifies the typed data whose type name is being requested.

StrBufferIndex

Receives the type name.

StrBufferChars

Specifies the size, in characters, of the ANSI string buffer **StrBufferIndex**.

StrCharsNeeded

Receives the size, in characters, of the type name.

Status

Receives the status code returned by this sub-operation. This is the same as the value returned by [Request](#).

Remarks

EXT_TDOP_GET_TYPE_NAME is a value in the [EXT_TDOP](#) enumeration.

The parameters for this sub-operation are members of the [EXT_TYPED_DATA](#) structure. The members of EXT_TYPED_DATA that are not listed in the preceding Parameters section are not used by this sub-operation and should be set to zero. The descriptions of the members in the preceding Parameters section specify what the members are used for. See [EXT_TYPED_DATA](#) for more details.

EXT_TDOP_OUTPUT_TYPE_NAME

The EXT_TDOP_OUTPUT_TYPE_NAME sub-operation of the [DEBUG_REQUEST_EXT_TYPED_DATA_ANSI Request](#) operation prints the type name of the specified typed data.

Parameters

Operation

Set to EXT_TDOP_OUTPUT_TYPE_NAME for this sub-operation.

InData

Specifies the typed data whose type name will be printed.

Status

Receives the status code returned by this sub-operation. This is the same as the value returned by [Request](#).

Remarks

The type name is sent to the debugger engine's [output callbacks](#).

EXT_TDOP_OUTPUT_TYPE_NAME is a value in the [EXT_TDOP](#) enumeration.

The parameters for this sub-operation are members of the [EXT_TYPED_DATA](#) structure. The members of EXT_TYPED_DATA that are not listed in the preceding Parameters section are not used by this sub-operation and should be set to zero. The descriptions of the members in the preceding Parameters section specify what the members are used for. See [EXT_TYPED_DATA](#) for more details.

EXT_TDOP_OUTPUT_SIMPLE_VALUE

The EXT_TDOP_OUTPUT_SIMPLE_VALUE sub-operation of the [DEBUG_REQUEST_EXT_TYPED_DATA_ANSI Request](#) operation prints the value of the specified typed data.

Parameters**Operation**

Set to EXT_TDOP_OUTPUT_SIMPLE_VALUE for this sub-operation.

InData

Specifies the typed data whose value will be printed.

Status

Receives the status code returned by this sub-operation. This is the same as the value returned by [Request](#).

Remarks

The value is formatted and is sent to the debugger engine's [output callbacks](#).

EXT_TDOP_OUTPUT_SIMPLE_VALUE is a value in the [EXT_TDOP](#) enumeration.

The parameters for this sub-operation are members of the [EXT_TYPED_DATA](#) structure. The members of EXT_TYPED_DATA that are not listed in the preceding Parameters section are not used by this sub-operation and should be set to zero. The descriptions of the members in the preceding Parameters section specify what the members are used for. See [EXT_TYPED_DATA](#) for more details.

© 2016 Microsoft. All rights reserved.

EXT_TDOP_OUTPUT_FULL_VALUE

The EXT_TDOP_OUTPUT_FULL_VALUE sub-operation of the [DEBUG REQUEST EXT_TYPED_DATA ANSI Request](#) operation prints the type and value of the specified typed data.

Parameters

Operation

Set to EXT_TDOP_OUTPUT_FULL_VALUE for this sub-operation.

InData

Specifies the typed data whose type name and value will be printed.

Status

Receives the status code returned by this sub-operation. This is the same as the value returned by [Request](#).

Remarks

The type name and formatted value are sent to the debugger engine's [output callbacks](#). EXT_TDOP_OUTPUT_FULL_VALUE prints more detailed information about the value than [EXT_TDOP_OUTPUT_SIMPLE_VALUE](#). For example, pointers are dereferenced and the values they point to are also printed.

EXT_TDOP_OUTPUT_FULL_VALUE is a value in the [EXT_TDOP](#) enumeration.

The parameters for this sub-operation are members of the [EXT_TYPED_DATA](#) structure. The members of EXT_TYPED_DATA that are not listed in the preceding Parameters section are not used by this sub-operation and should be set to zero. The descriptions of the members in the preceding Parameters section specify what the members are used for. See [EXT_TYPED_DATA](#) for more details.

EXT_TDOP_HAS_FIELD

The EXT_TDOP_HAS_FIELD sub-operation of the [DEBUG REQUEST EXT_TYPED_DATA ANSI Request](#) operation determines if a structure contains a specified member.

Parameters

Operation

Set to EXT_TDOP_HAS_FIELD for this sub-operation.

InData

Specifies the typed data that is checked for the existence of the member. The typed data is first checked to see if it represents an instance of a structure, then the structure is checked to see if it contains the specified member.

InStrIndex

Specifies the name of the member. The name is a dot-separated path and can contain sub-members - for example, **mymember.mysubmember**. Pointers on this dot-separated path will automatically be dereferenced. However, a dot operator (.) should still be used here instead of the usual C pointer dereference operator (->).

Status

Receives the status code returned by this sub-operation. This is the same as the value returned by [Request](#).

If the typed data contains the member, **Status** receives S_OK. If the typed data does not contain the member, **Status** receives E_NOINTERFACE. Other error values might also be returned.

Remarks

EXT_TDOP_HAS_FIELD is a value in the [EXT_TDOP](#) enumeration.

The parameters for this sub-operation are members of the [EXT_TYPED_DATA](#) structure. The members of EXT_TYPED_DATA that are not listed in the preceding Parameters section are not used by this sub-operation and should be set to zero. The descriptions of the members in the preceding Parameters section specify what the members are used for. See [EXT_TYPED_DATA](#) for more details.

EXT_TDOP_GET_FIELD_OFFSET

The EXT_TDOP_GET_FIELD_OFFSET sub-operation of the [DEBUG_REQUEST_EXT_TYPED_DATA_ANSI Request](#) operation returns the offset of a member within a structure.

Parameters

Operation

Set to EXT_TDOP_GET_FIELD_OFFSET for this sub-operation.

InData

Specifies the typed data that represents an instance of a structure that contains the member whose offset is being requested.

InStrIndex

Specifies the name of the member whose offset is being requested. The name is a dot-separated path and can contain sub-members. For example, `mymember.mysubmember`. Pointers on this dot-separated path will automatically be dereferenced. However, a dot operator (.) should still be used here instead of the usual C pointer dereference operator (>).

Out32

Receives the offset of the member within an instance of the structure. This is the number of bytes between the beginning of an instance of the structure and the member.

Status

Receives the status code returned by this sub-operation. This is the same as the value returned by [Request](#).

Remarks

EXT_TDOP_GET_FIELD_OFFSET is a value in the [EXT_TDOP](#) enumeration.

The parameters for this sub-operation are members of the [EXT_TYPED_DATA](#) structure. The members of EXT_TYPED_DATA that are not listed in the preceding Parameters section are not used by this sub-operation and should be set to zero. The descriptions of the members in the preceding Parameters section specify what the members are used for. See [EXT_TYPED_DATA](#) for more details.

EXT_TDOP_GET_ARRAY_ELEMENT

The EXT_TDOP_GET_ARRAY_ELEMENT sub-operation of the [DEBUG_REQUEST_EXT_TYPED_DATA_ANSI Request](#) operation returns an element from an array.

Parameters

Operation

Set to EXT_TDOP_GET_ARRAY_ELEMENT for this sub-operation.

InData

Specifies the array whose element is being requested. InData can also specify a pointer, in which case it is treated as an array.

OutData

Receives the requested element from the array.

In64

Specifies the index of the element in the array.

Status

Receives the status code returned by this sub-operation. This is the same as the value returned by [Request](#).

Remarks

EXT_TDOP_GET_ARRAY_ELEMENT is a value in the [EXT_TDOP](#) enumeration.

The parameters for this sub-operation are members of the [EXT_TYPED_DATA](#) structure. The members of EXT_TYPED_DATA that are not listed in the preceding Parameters section are not used by this sub-operation and should be set to zero. The descriptions of the members in the preceding Parameters section specify what the members are used for. See [EXT_TYPED_DATA](#) for more details.

EXT_TDOP_GET_DEREFERENCE

The EXT_TDOP_GET_DEREFERENCE sub-operation of the [DEBUG_REQUEST_EXT_TYPED_DATA_ANSI Request](#) operation dereferences a pointer and returns the value it points to.

Parameters**Operation**

Set to EXT_TDOP_GET_DEREFERENCE for this sub-operation.

InData

Specifies the pointer to dereference. **InData** can also specify an array, in which case the first element in the array is returned.

OutData

Receives the value pointed to.

Status

Receives the status code returned by this sub-operation. This is the same as the value returned by [Request](#).

Remarks

EXT_TDOP_GET_DEREFERENCE is a value in the [EXT_TDOP](#) enumeration.

The parameters for this sub-operation are members of the [EXT_TYPED_DATA](#) structure. The members of EXT_TYPED_DATA that are not listed in the preceding Parameters section are not used by this sub-operation and should be set to zero. The descriptions of the members in the preceding Parameters section specify what the members are used for. See [EXT_TYPED_DATA](#) for more details.

EXT_TDOP_GET_TYPE_SIZE

The EXT_TDOP_GET_TYPE_SIZE sub-operation of the [DEBUG REQUEST EXT TYPED DATA ANSI Request](#) operation returns the size of the specified typed data.

Parameters

Operation

Set to EXT_TDOP_GET_TYPE_SIZE for this sub-operation.

InData

Specifies the typed data whose size is being requested.

Out32

Receives the size, in bytes, of the typed data.

Status

Receives the status code returned by this sub-operation. This is the same as the value returned by [Request](#).

Remarks

EXT_TDOP_GET_TYPE_SIZE is a value in the [EXT_TDOP](#) enumeration.

The parameters for this sub-operation are members of the [EXT_TYPED_DATA](#) structure. The members of EXT_TYPED_DATA that are not listed in the preceding Parameters section are not used by this sub-operation and should be set to zero. The descriptions of the members in the preceding Parameters section specify what the members are used for. See [EXT_TYPED_DATA](#) for more details.

EXT_TDOP_OUTPUT_TYPE_DEFINITION

The EXT_TDOP_OUTPUT_TYPE_DEFINITION sub-operation of the [DEBUG REQUEST EXT TYPED DATA ANSI Request](#) operation prints the definition of the type for the specified typed data.

Parameters

Operation

Set to EXT_TDOP_OUTPUT_TYPE_DEFINITION for this sub-operation.

InData

Specifies the typed data whose type's definition will be printed.

Status

Receives the status code returned by this sub-operation. This is the same as the value returned by [Request](#).

Remarks

The definition of the type is formatted and sent to the debugger engine's [output callbacks](#).

EXT_TDOP_OUTPUT_TYPE_DEFINITION is a value in the [EXT_TDOP](#) enumeration.

The parameters for this sub-operation are members of the [EXT_TYPED_DATA](#) structure. The members of EXT_TYPED_DATA that are not listed in the preceding Parameters section are not used by this sub-operation and should be set to zero. The descriptions of the members in the preceding Parameters section specify what the members are used for. See [EXT_TYPED_DATA](#) for more details.

EXT_TDOP_GET_POINTER_TO

The EXT_TDOP_GET_POINTER_TO sub-operation of the [DEBUG_REQUEST_EXT_TYPED_DATA_ANSI Request](#) operation returns a new typed data description that represents a pointer to specified typed data.

Parameters**Operation**

Set to EXT_TDOP_GET_POINTER_TO for this sub-operation.

InData

Specifies the original typed data description to which a pointer is returned.

OutData

Receives a typed data description that represents a pointer to the typed data specified by **InData**.

Status

Receives the status code returned by this sub-operation. This is the same as the value returned by [Request](#).

Remarks

EXT_TDOP_GET_POINTER_TO is a value in the [EXT_TDOP](#) enumeration.

The parameters for this sub-operation are members of the [EXT_TYPED_DATA](#) structure. The members of EXT_TYPED_DATA that are not listed in the preceding Parameters section are not used by this sub-operation and should be set to zero. The descriptions of the members in the preceding Parameters section specify what the members are used for. See [EXT_TYPED_DATA](#) for more details.

EXT_TDOP_SET_FROM_TYPE_ID_AND_U64

The EXT_TDOP_SET_FROM_TYPE_ID_AND_U64 sub-operation of the [DEBUG_REQUEST_EXT_TYPED_DATA_ANSI Request](#) operation creates a typed data description from a data type and a memory location.

Parameters**Operation**

Set to EXT_TDOP_SET_FROM_TYPE_ID_AND_U64 for this sub-operation.

Flags

Specifies the bit flags that describe the target's memory in which the value of the typed data resides. See [EXT_TYPED_DATA](#) for details of these flags.

InData

Specifies the type and the memory location. This instance of the [DEBUG_TYPED_DATA](#) structure can be manually created and populated with the required members. The following members are used:

ModBase

Specifies the location in the target's virtual memory of the base address of the module that contains the type.

Offset

Specifies the location in the target's memory of the data. **Offset** is a virtual memory address unless there are flags present in **Flags** that specify that **Offset** is a physical memory address.

TypeId

Specifies the type ID of the type.

OutData

Receives the typed data description.

Status

Receives the status code returned by this sub-operation. This is the same as the value returned by [Request](#).

Remarks

EXT_TDOP_SET_FROM_TYPE_ID_AND_U64 is a value in the [EXT_TDOP](#) enumeration.

The parameters for this sub-operation are members of the [EXT_TYPED_DATA](#) structure. The members of EXT_TYPED_DATA that are not listed in the preceding Parameters section are not used by this sub-operation and should be set to zero. The descriptions of the members in the preceding Parameters section specify what the members are used for. See [EXT_TYPED_DATA](#) for more details.

EXT_TDOP_SET_PTR_FROM_TYPE_ID_AND_U64

The EXT_TDOP_SET_PTR_FROM_TYPE_ID_AND_U64 sub-operation of the [DEBUG REQUEST EXT TYPED DATA ANSI Request](#) operation creates a typed data description that represents a pointer to a specified memory location with a specified type.

Parameters**Operation**

Set to EXT_TDOP_SET_PTR_FROM_TYPE_ID_AND_U64 for this sub-operation.

Flags

Specifies the bit flags that describe the target's memory in which the value of the typed data resides. See [EXT_TYPED_DATA](#) for details of these flags.

InData

Specifies the type and memory location. This instance of the [DEBUG_TYPED_DATA](#) structure can be manually created and populated with the required members. The following members are used:

ModBase

Specifies the location in the target's virtual memory of the base address of the module that contains the type.

Offset

Specifies the location in the target's memory of the data. **Offset** is a virtual memory address unless there are flags present in **Flags** that specify that **Offset** is a physical memory address.

TypeId

Specifies the type ID of the type.

OutData

Receives the typed data description that represents a pointer to the memory location and type.

Status

Receives the status code returned by this sub-operation. This is the same as the value returned by [Request](#).

Remarks

`EXT_TDOP_SET_PTR_FROM_TYPE_ID_AND_U64` is a value in the [EXT_TDOP](#) enumeration.

The parameters for this sub-operation are members of the [EXT_TYPED_DATA](#) structure. The members of `EXT_TYPED_DATA` that are not listed in the preceding Parameters section are not used by this sub-operation and should be set to zero. The descriptions of the members in the preceding Parameters section specify what the members are used for. See [EXT_TYPED_DATA](#) for more details.

IDebugAdvanced3 interface

Members

The `IDebugAdvanced3` interface inherits from [IDebugAdvanced2](#). `IDebugAdvanced3` also has these types of members:

- [Methods](#)

Methods

The `IDebugAdvanced3` interface has these methods.

Method	Description
FindSourceFileAndTokenWide	Returns the filename of a source file on the source path or return the value of a variable associated with a file token.
GetSourceFileInfoWide	Returns specified information about a source file.
GetSymbolInformationWide	Returns specified information about a symbol.

Requirements

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugAdvanced2](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugAdvanced3::FindSourceFileAndTokenWide method

The `FindSourceFileAndTokenWide` method returns the filename of a source file on the source path or return the value of a variable associated with a file token.

Syntax

C++

```
HRESULT FindSourceFileAndTokenWide(
    [in]          ULONG      StartElement,
    [in]          ULONG64     ModAddr,
    [in]          PCWSTR      File,
    [in]          ULONG      Flags,
    [in, optional] PVOID      FileToken,
    [in]          ULONG      FileTokenSize,
    [out, optional] PULONG    FoundElement,
    [out, optional] PWSTR     Buffer,
    [in]          ULONG      BufferSize,
    [out, optional] PULONG    FoundSize
);
```

Parameters

StartElement [in]

Specifies the index of an element within the source path to start searching from. All elements in the source path before *StartElement* are excluded from the search. The index of the first element is zero. If *StartElement* is greater than or equal to the number of elements in the source path, the filing system is checked directly.

This parameter can be used with *FoundElement* to check for multiple matches in the source path.

StartElement is ignored if the flag DEBUG_FIND_SOURCE_TOKEN_LOOKUP is set in *Flags*.

ModAddr [in]

Specifies a location within the memory allocation of the module in the target to which the source file is related. *ModAddr* is used for caching the search results and when querying source servers for the file. *ModAddr* can be **NULL**.

ModAddr is ignored if the flag DEBUG_FIND_SOURCE_TOKEN_LOOKUP is set in *Flags*. And it is not used for querying source servers if *FileToken* is not **NULL**.

File [in]

Specifies the path and filename of the file to search for.

If the flag DEBUG_FIND_SOURCE_TOKEN_LOOKUP is set, the file is already specified by the token in *FileToken*. In this case, *File* specifies the name of a variable on the source server related to the file. The variable must begin and end with the percent sign (%), for example, %SRCRVCMD%. The value of this variable is returned.

Flags [in]

Specifies the flags that control the behavior of this method. For a description of these flags, see [DEBUG_FIND_SOURCE_XXX](#).

FileToken [in, optional]

Specifies a file token representing a file on a source server. A file token can be obtained by setting *Which* to DEBUG_SRCFILE_SYMBOL_TOKEN in the method [GetSourceFileInfo](#).

If the flag DEBUG_FIND_SOURCE_TOKEN_LOOKUP is set, *FileToken* must not be **NULL**.

FileTokenSize [in]

Specifies the size in bytes of the *FileToken* token. If *FileToken* is **NULL**, this parameter is ignored.

FoundElement [out, optional]

Receives the index of the element within the source path that contained the file. If the file was found directly on the filing system (not using the source path), -1 is returned to *FoundElement*. If *FoundElement* is **NULL** or *Flags* contain DEBUG_SRCFILE_SYMBOL_TOKEN, this information is not returned.

Buffer [out, optional]

Receives the name of the file that was found. If the file is not on a source server, this is the name of the file in the local source cache. If the flag DEBUG_FIND_SOURCE_FULL_PATH is set, this is the full canonical path name for the file. Otherwise, it is the concatenation of the directory in the source path with the tail of *File* that was used to find the file.

If the flag DEBUG_SRCFILE_SYMBOL_TOKEN is set in *Flags*, *Buffer* receives the value of the variable named *File* associated with the file token *FileToken*.

If *Buffer* is **NULL**, this information is not returned.

BufferSize [in]

Specifies the size in characters of the *Buffer* buffer. If *Buffer* is **NULL**, this parameter is ignored.

FoundSize [out, optional]

Specifies the size in characters of the name of the file. If *foundSize* is **NULL**, this information is not returned.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
S_FALSE	The method was successful. However, the <i>Buffer</i> buffer was too small to hold the file name or variable value, so the string was truncated to fit in the buffer.

Remarks

When the flag DEBUG_SRCFILE_SYMBOL_TOKEN is set in *Flags*, this method does not search for a file on the source path. Instead, it looks up a variable associated with the file token provided in *FileToken*. These variables are documented in the topic [Language Specification 1](#). For example, to retrieve the value of the variable SRCSRVCMD—the command to extract the source file from source control (also returned by the DEBUG_SRCFILE_SYMBOL_TOKEN_SOURCE_COMMAND_WIDE function of [GetSourceFileInfo](#))—set *File* to %SRCRVCMD%.

The engine uses the following steps--in order--to search for the file:

1. If the source path contains any source servers and the flag DEBUG_FIND_SOURCE_NO_SRCSRV is not set, the source server in the source path is searched first.
The first match found is returned.
2. For each directory in the source path, an attempt is made to find an overlap between the end of the directory path and the beginning of the file path. For example, if the source path contains a directory C:\a\b\c\d and *File* is c\d\e\foo.c, the file C:\a\b\c\d\e\foo.c is a match.
If the flag DEBUG_FIND_SOURCE_BEST_MATCH is set, the match with the longest overlap is returned; otherwise, the first match is returned.
3. For each directory in the source path, *File* is appended to the directory. If no match is found, this process is repeated and each time the first directory is removed from the beginning of the file path. For example, if the source path contains a directory C:\a\b and *File* is c\d\e\foo.c, the file C:\a\b\c\d\e\foo.c is a match.
The first match found is returned.
4. The file *File* is looked up directly on the filing system.

For more information about source files, see [Using Source Files](#). For an overview of the source path and its syntax, see [Source Path](#).

Requirements

IDebugAdvanced3::GetSourceFileInformationWide method

The **GetSourceFileInformationWide** method returns specified information about a source file.

Syntax

C++

```
HRESULT GetSourceFileInformationWide(
    [in]          ULONG    Which,
    [in]          PWSTR    SourceFile,
    [in]          ULONG64 Arg64,
    [in]          ULONG    Arg32,
    [out, optional] PVOID   Buffer,
    [in]          ULONG    BufferSize,
    [out, optional] PULONG  InfoSize
);
```

Parameters

Which [in]

Specifies the piece of information to return. The *Which* parameter can take one of the values in the following table.

DEBUG_SRCFILE_SYMBOL_TOKEN

Returns a token representing the specified source file on a source server. This token can be passed to [FindSourceFileAndToken](#) to retrieve information about the file. The token is returned to the *Buffer* buffer as an array of bytes. The size of this token is a reflection of the size of the SrcSrv token.

DEBUG_SRCFILE_SYMBOL_TOKEN_SOURCE_COMMAND_WIDE

Queries a source server for the command to extract the source file from source control. This includes the name of the executable file and its command-line parameters. The command is returned to the *Buffer* buffer as a Unicode string.

SourceFile [in]

Specifies the source file whose information is being requested. The source file is looked up on all the source servers in the source path.

Arg64 [in]

Specifies a 64-bit argument. The value of *Which* specifies the module whose symbol token is requested. Regardless of the value of *Which*, *Arg64* is a location within the

memory allocation of the module.

Arg32 [in]

Specifies a 32-bit argument. This parameter is currently unused.

Buffer [out, optional]

Receives the requested symbol information. The type of the data returned depends on the value of *Which*. If *Buffer* is **NULL**, this information is not returned.

BufferSize [in]

Specifies the size in bytes of the *Buffer* buffer. If *Buffer* is **NULL**, *BufferSize* must also be **NULL**.

InfoSize [out, optional]

Specifies the size in bytes of the information returned to the *Buffer* buffer. This parameter can be **NULL** if the data is not required.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
S_FALSE	The method was successful. However, the information would not fit in the <i>Buffer</i> buffer, so the information or name was truncated.

Remarks

For more information about source files, see [Using Source Files](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugAdvanced3::GetSymbolInformationWide method

The **SetSymbolInformationWide** method returns specified information about a symbol.

Syntax

```
C++
HRESULT GetSymbolInformationWide (
    [in]          ULONG      Which,
    [in]          ULONG64    Arg64,
    [in]          ULONG      Arg32,
    [out, optional] PVOID     Buffer,
    [in]          ULONG      BufferSize,
    [out, optional] PULONG    InfoSize,
    [out, optional] PWSTR     StringBuffer,
    [in]          ULONG      StringBufferSize,
    [out, optional] PULONG    StringSize
);
```

Parameters

Which [in]

Specifies the piece of information to return. *Which* can take one of the values in the follow table.

Value	Information returned
DEBUG_SYMINFO_BREAKPOINT_SOURCE_LINE	Returns the source code file name and line number for a specified breakpoint. The line number is returned to <i>Buffer</i> as a ULONG. The file name is returned to

DEBUG_SYMINFO_IMAGEHELP_MODULEW64

StringBuffer.

Returns an IMAGEHELP_MODULEW64 structure that describes a specified module. For details about this structure, see the IMAGEHELP_MODULE64 topic in the Debug Help Library documentation (dbghelp.chm).

DEBUG_SYMINFO_GET_SYMBOL_NAME_BY_OFFSET_AND_TAG_WIDE

No string is returned and *StringBuffer*, *StringBufferSize*, and *StringSize* must all be set to zero.

Returns the Unicode name of the symbol specified by location in memory and PDB tag type. The name is returned to *Buffer*. *StringBuffer* is not used.

DEBUG_SYMINFO_GET_MODULE_SYMBOL_NAMES_AND_OFFSETS

Returns a list of symbol names and offsets for the symbols in the specified module with the specified PDB tag type. The offsets are returned as an array of ULONG values to *Buffer*. The names are returned in the same order as the offsets to *StringBuffer*. Some names might contain embedded zeros because annotations can have multi-part names; hence, each name is terminated with two null characters.

Arg64 [in]

Specifies a 64-bit argument. This parameter has the following interpretations depending on the value of *Which*:

DEBUG_SYMINFO_BREAKPOINT_SOURCE_LINE

Ignored.

DEBUG_SYMINFO_IMAGEHELP_MODULEW64

The base address of the module whose description is being requested.

DEBUG_SYMINFO_GET_SYMBOL_NAME_BY_OFFSET_AND_TAG_WIDE

Specifies the address in the target's memory of the symbol whose name is being requested.

DEBUG_SYMINFO_GET_MODULE_SYMBOL_NAMES_AND_OFFSETS

Specifies the module whose symbols are requested. *Arg64* is a location within the memory allocation of the module.

Arg32 [in]

Specifies a 32-bit argument. This parameter has the following interpretations depending on the value of *Which*:

DEBUG_SYMINFO_BREAKPOINT_SOURCE_LINE

The engine breakpoint ID of the desired breakpoint.

DEBUG_SYMINFO_IMAGEHELP_MODULEW64

Set to zero.

DEBUG_SYMINFO_GET_SYMBOL_NAME_BY_OFFSET_AND_TAG_WIDE

The PDB classification of the symbol. *Arg32* must be one of the values in the **SymTagEnum** enumeration defined in Dbghelp.h. For more information, see PDB documentation.

DEBUG_SYMINFO_GET_MODULE_SYMBOL_NAMES_AND_OFFSETS

The PDB classification of the symbol. *Arg32* must be one of the values in the **SymTagEnum** enumeration defined in Dbghelp.h. For more information, see PDB documentation.

Buffer [out, optional]

Receives the requested symbol information. The type of the data returned depends on the value of *Which*. If *Buffer* is **NULL**, this information is not returned.

BufferSize [in]

Specifies the size, in bytes, of the buffer *Buffer*.

InfoSize [out, optional]

If this method returns **S_OK**, *InfoSize* receives the size, in bytes, of the symbol information returned to *Buffer*. If this method returns **S_FALSE**, the supplied buffer is not big enough, and *InfoSize* receives the required buffer size. If *InfoSize* is **NULL**, this information is not returned.

StringBuffer [out, optional]

Receives the requested string. The interpretation of this string depends on the value of *Which*. If *StringBuffer* is **NULL**, this information is not returned.

StringBufferSize [in]

Specifies the size, in characters, of the string buffer *StringBuffer*.

StringSize [out, optional]

Receives the size, in characters, of the string returned to *StringBuffer*. If *StringSize* is **NULL**, this information is not returned.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
S_FALSE	The method was successful. However, the information would not fit in the buffer <i>Buffer</i> or the string would not fit in the buffer <i>StringBuffer</i> , so the information or name was truncated.

IDebugAdvanced4::GetSymbolInformationWideEx method

The **GetSymbolInformationWideEx** method returns specified information about a symbol.

Syntax

C++

```
HRESULT GetSymbolInformationWideEx(
    [in]           ULONG          Which,
    [in]           ULONG64        Arg64,
    [in]           ULONG          Arg32,
    [out, optional] PVOID         Buffer,
    [in]           ULONG          BufferSize,
    [out, optional] PULONG        InfoSize,
    [out, optional] PWSTR         StringBuffer,
    [in]           ULONG          StringBufferSize,
    [out, optional] PULONG        StringSize,
    [out, optional] PSYMBOL_INFO_EX pInfoEx
);
```

Parameters

Which [in]

Specifies the piece of information to return. *Which* can take one of the values in the follow table.

Value	Information returned
DEBUG_SYMINFO_BREAKPOINT_SOURCE_LINE	Returns the source code file name and line number for a specified breakpoint. The line number is returned to <i>Buffer</i> as a ULONG. The file name is returned to <i>StringBuffer</i> .
DEBUG_SYMINFO_IMAGEHELP_MODULEW64	Returns an IMAGEHELP_MODULEW64 structure that describes a specified module. For details about this structure, see the IMAGEHELP_MODULE64 topic in the Debug Help Library documentation (dbghelp.chm).
DEBUG_SYMINFO_GET_SYMBOL_NAME_BY_OFFSET_AND_TAG_WIDE	No string is returned and <i>StringBuffer</i> , <i>StringBufferSize</i> , and <i>StringSize</i> must all be set to zero.
DEBUG_SYMINFO_GET_MODULE_SYMBOL_NAMES_AND_OFFSETS	Returns the Unicode name of the symbol specified by location in memory and PDB tag type. The name is returned to <i>Buffer</i> . <i>StringBuffer</i> is not used. Returns a list of symbol names and offsets for the symbols in the specified module with the specified PDB tag type. The offsets are returned as an array of ULONG values to <i>Buffer</i> . The names are returned in the same order as the offsets to <i>StringBuffer</i> . Some names might contain embedded zeros because annotations can have multi-part names; hence, each name is terminated with two null characters.

Arg64 [in]

Specifies a 64-bit argument. This parameter has the following interpretations depending on the value of *Which*:

DEBUG_SYMINFO_BREAKPOINT_SOURCE_LINE

Ignored.

DEBUG_SYMINFO_IMAGEHELP_MODULEW64

The base address of the module whose description is being requested.

DEBUG_SYMINFO_GET_SYMBOL_NAME_BY_OFFSET_AND_TAG_WIDE

Specifies the address in the target's memory of the symbol whose name is being requested.

DEBUG_SYMINFO_GET_MODULE_SYMBOL_NAMES_AND_OFFSETS

Specifies the module whose symbols are requested. *Arg64* is a location within the memory allocation of the module.

Arg32 [in]

Specifies a 32-bit argument. This parameter has the following interpretations depending on the value of *Which*:

DEBUG_SYMINFO_BREAKPOINT_SOURCE_LINE

The engine breakpoint ID of the desired breakpoint.

DEBUG_SYMINFO_IMAGEHELP_MODULEW64

Set to zero.

DEBUG_SYMINFO_GET_SYMBOL_NAME_BY_OFFSET_AND_TAG_WIDE

The PDB classification of the symbol. *Arg32* must be one of the values in the **SymTagEnum** enumeration defined in Dbghelp.h. For more information, see PDB documentation.

DEBUG_SYMINFO_GET_MODULE_SYMBOL_NAMES_AND_OFFSETS

The PDB classification of the symbol. *Arg32* must be one of the values in the **SymTagEnum** enumeration defined in Dbghelp.h. For more information, see PDB documentation.

Buffer [out, optional]

Receives the requested symbol information. The type of the data returned depends on the value of *Which*. If *Buffer* is **NULL**, this information is not returned.

BufferSize [in]

Specifies the size, in bytes, of the buffer *Buffer*.

InfoSize [out, optional]

If this method returns **S_OK**, *InfoSize* receives the size, in bytes, of the symbol information returned to *Buffer*. If this method returns **S_FALSE**, the supplied buffer is not big enough, and *InfoSize* receives the required buffer size. If *InfoSize* is **NULL**, this information is not returned.

StringBuffer [out, optional]

Receives the requested string. The interpretation of this string depends on the value of *Which*. If *StringBuffer* is **NULL**, this information is not returned.

StringBufferSize [in]

Specifies the size, in characters, of the string buffer *StringBuffer*.

StringSize [out, optional]

Receives the size, in characters, of the string returned to *StringBuffer*. If *StringSize* is **NULL**, this information is not returned.

pInfoEx [out, optional]

A pointer to a [SYMBOL_INFO_EX](#) structure.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
S_FALSE	The method was successful. However, the information would not fit in the buffer <i>Buffer</i> or the string would not fit in the buffer <i>StringBuffer</i> , so the information or name was truncated.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugClient interface

Members

The **IDebugClient** interface inherits from the **IUnknown** interface. **IDebugClient** also has these types of members:

- [Methods](#)

Methods

The **IDebugClient** interface has these methods.

Method	Description
AddProcessOptions	Adds the process options to those options that affect the current process.
AttachKernel	Connects the debugger engine to a kernel target.
AttachProcess	Connects the debugger engine to a user-mode process.
ConnectProcessServer	Connects to a process server.
ConnectSession	Joins the client to an existing debugger session.
CreateClient	Creates a new client object for the current thread.
CreateProcess	Creates a process from the specified command line.
CreateProcessAndAttach	Create a process from a specified command line, then attaches to another user-mode process.
DetachProcesses	Detaches the debugger engine from all processes in all targets, resuming all their threads.
DisconnectProcessServer	Disconnects the debugger engine from a process server.
DispatchCallbacks	Enables the debugger engine to use the current thread for callbacks.
EndSession	Ends the current debugger session.
ExitDispatch	Causes the DispatchCallbacks method to return.
FlushCallbacks	Forces any remaining buffered output to be delivered to the IDebugOutputCallbacks object registered with this client.
GetEventCallbacks	Returns the event callbacks object registered with this client.
GetExitCode	Returns the exit code of the current process if that process has already run through to completion.
GetIdentity	Returns a string describing the computer and user this client represents.
GetInputCallbacks	Returns the input callbacks object registered with this client.
GetKernelConnectionOptions	Returns the connection options for the current kernel target.
GetOtherOutputMask	Returns the output mask for another client.
GetOutputCallbacks	Returns the output callbacks object registered with the client.
GetOutputLinePrefix	Returns the output mask currently set for the client.
GetOutputMask	Returns the output mask currently set for the client.

GetOutputWidth	Retrieves the process options affecting the current process.
GetProcessOptions	Returns a description of the process that includes the executable image name, the service names, the MTS package names, and the command line.
GetRunningProcessDescription	Searches for a process with a given executable file name and return its process ID.
GetRunningProcessSystemIdByExecutableName	Returns the process IDs for each running process.
GetRunningProcessSystemIds	Opens a dump file as a debugger target.
OpenDumpFile	Formats and outputs a string describing the computer and user this client represents.
OutputIdentity	Lists the servers running on a given computer.
OutputServers	Removes process options from those options that affect the current process.
RemoveProcessOptions	Registers an event callbacks object with this client.
SetEventCallbacks	Registers an input callbacks object with the client.
SetInputCallbacks	Updates some of the connection options for a live kernel target.
SetKernelConnectionOptions	Sets the output mask for another client.
SetOtherOutputMask	Registers an output callbacks object with this client.
SetOutputCallbacks	Sets the output mask for the client.
SetOutputLinePrefix	Sets the process options affecting the current process.
SetOutputMask	Starts a process server.
SetOutputWidth	Starts a debugging server.
SetProcessOptions	Attempts to terminate all processes in all targets.
StartProcessServer	Creates a user-mode or kernel-mode crash dump file.
StartServer	
TerminateProcesses	
WriteDumpFile

IDebugClient::AddProcessOptions method

The **AddProcessOptions** method adds the process options to those options that affect the [current process](#).

Syntax

```
C++  
HRESULT AddProcessOptions(  
    [in] ULONG Options  
) ;
```

Parameters

Options [in]

Specifies the process options to add to those affecting the current process. For details on these process options, see [DEBUG_PROCESS_XXX](#).

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

This method is available only in [live user-mode debugging](#).

Some of the process options are global options, others are specific to the current process.

If any process options are modified, the engine will notify the [event callbacks](#) by calling their [IDebugEventCallbacks::ChangeEngineState](#) method with the DEBUG_CES_PROCESS_OPTIONS flag set.

For more information about creating and attaching to live user-mode targets, see [Live User-Mode Targets](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

IDebugClient::AttachKernel method

The **AttachKernel** methods connect the [debugger engine](#) to a kernel target.

Syntax

```
C++
HRESULT AttachKernel(
    [in]           ULONG Flags,
    [in, optional] PCSTR ConnectOptions
);
```

Parameters

Flags [in]

Specifies the flags that control how the debugger attaches to the kernel target. The possible values are:

Value	Description
DEBUG_ATTACH_KERNEL_CONNECTION	Attach to the kernel on the target computer.
DEBUG_ATTACH_EXDI_DRIVER	Attach to a kernel by using an eXDI driver.

ConnectOptions [in, optional]

Specifies the connection settings for communicating with the computer running the kernel target. The interpretation of *ConnectOptions* depends on the value of *Flags*.

DEBUG_ATTACH_KERNEL_CONNECTION

ConnectOptions will be interpreted the same way as the options that follow the **-k** switch on the WinDbg and KD command lines. Environment variables affect *ConnectOptions* in the same way they affect the **-k** switch.

DEBUG_ATTACH_EXDI_DRIVER

eXDI drivers are not described in this documentation. If you have an eXDI interface to your hardware probe or hardware simulator, please contact Microsoft for debugging information.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

Note The engine doesn't completely attach to the kernel until the [WaitForEvent](#) method has been called. Only after the kernel has generated an event -- for example, the initial breakpoint -- does it become available in the debugger session.

For more information about connecting to live kernel-mode targets, see [Live Kernel-Mode Targets](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugClient::AttachProcess method

The **AttachProcess** method connects the [debugger engine](#) to a user-mode process.

Syntax

```
C++  
HRESULT AttachProcess(  
    [in] ULONG64 Server,  
    [in] ULONG    ProcessId,  
    [in] ULONG    AttachFlags  
) ;
```

Parameters

Server [in]

Specifies the process server to use to attach to the process. If *Server* is zero, the engine will connect to a local process without using a process server.

ProcessId [in]

Specifies the process ID of the target process the debugger will attach to.

AttachFlags [in]

Specifies the flags that control how the debugger attaches to the target process. For details on these flags, see [DEBUG_ATTACH_XXX](#).

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

This method is available only for live user-mode debugging.

Note The engine doesn't completely attach to the process until the [WaitForEvent](#) method has been called. Only after the process has generated an event -- for example, the create-process event -- does it become available in the debugger session.

For more information about creating and attaching to live user-mode targets, see [Live User-Mode Targets](#).

Requirements

Target platform

IDebugClient::ConnectProcessServer method

The **ConnectProcessServer** methods connect to a [process server](#).

Syntax

```
C++  
HRESULT ConnectProcessServer(  
    [in] PCSTR    RemoteOptions,  
    [out] PULONG64 Server  
) ;
```

Parameters

RemoteOptions [in]

Specifies how the [debugger engine](#) will connect with the process server. These are the same options passed to the **-premote** option on the WinDbg and CDB command lines. For details on the syntax of this string, see [Activating a Smart Client](#).

Server [out]

Receives a handle for the process server. This handle is used when creating or attaching to processes by using the process server.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

For more information about process servers and remote debugging, see [Process Servers, Kernel Connection Servers, and Smart Clients](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

IDebugClient::ConnectSession method

The **ConnectSession** method joins the client to an existing debugger session.

Syntax

```
C++  
HRESULT ConnectSession(  
    [in] ULONG Flags,  
    [in] ULONG HistoryLimit  
) ;
```

Parameters

Flags [in]

Specifies a bit-set of option flags for connecting to the session. The possible values of these flags are:

Flag	Description
DEBUG_CONNECT_SESSION_NO_VERSION	Do not output the debugger engine 's version to this client.
DEBUG_CONNECT_SESSION_NO_ANNOUNCE	Do not output a message notifying other clients that this client has connected.

HistoryLimit [in]

Specifies the maximum number of characters from the session's history to send to this client's output upon connection.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

When the client object connects to a session, the most recent output from the session is sent to the client. If the session is currently waiting on input, the client object is given the opportunity to provide input. Thus, the client object synchronizes with the session's input and output.

The client becomes a primary client and will appear among the list of clients in the output of the [.clients](#) debugger command.

For more information about debugging clients, see Debugging Server and Debugging Client. For more information about debugger sessions, see [Debugging Session and Execution Model](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugClient::CreateClient method

The **CreateClient** method creates a new client object for the current thread.

Syntax

```
C++
HRESULT CreateClient(
    [out] IDebugClient **Client
);
```

Parameters

Client [out]

Receives an interface pointer for the new client.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

This method creates a client that may be used in the current thread.

Clients are specific to the thread that created them. Calls from other threads fail immediately. The **CreateClient** method is a notable exception; it allows creation of a new client for a new thread.

All callbacks for a client are made in the thread with which the client was created.

For more information about client objects and how they are used in the debugger engine, see [Client Objects](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugClient](#)

© 2016 Microsoft. All rights reserved.

IDebugClient::CreateProcess method

The **CreateProcess** method creates a process from the specified command line.

Syntax

```
C++  
HRESULT CreateProcess(  
    [in] ULONG64 Server,  
    [in] PSTR    CommandLine,  
    [in] ULONG   CreateFlags  
) ;
```

Parameters

Server [in]

Specifies the process server to use to attach to the process. If *Server* is zero, the engine will create a local process without using a process server.

CommandLine [in]

Specifies the command line to execute to create the new process.

CreateFlags [in]

Specifies the flags to use when creating the process. For details on these flags, see the **CreateFlags** member of the [DEBUG_CREATE_PROCESS_OPTIONS](#) structure.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

This method is available only for live user-mode debugging.

If *CreateFlags* contains either of the flags DEBUG_PROCESS or DEBUG_ONLY_THIS_PROCESS, the engine will also attach to the newly created process; this is similar to the behavior of [CreateProcessAndAttach2](#) with its argument *ProcessId* set to zero.

For more information about creating and attaching to live user-mode targets, see [Live User-Mode Targets](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugClient::CreateProcessAndAttach method

The **CreateProcessAndAttach** method creates a process from a specified command line, then attach to another user-mode process. The created process is suspended and only allowed to execute when the attach has completed. This allows rough synchronization when debugging both, client and server processes.

Syntax

C++

```
HRESULT CreateProcessAndAttach(  
    [in]          ULONG64 Server,  
    [in, optional] PSTR    CommandLine,  
    [in]          ULONG   CreateFlags,  
    [in]          ULONG   ProcessId,
```

```
[in]          ULONG    AttachFlags  
) ;
```

Parameters

Server [in]

Specifies the process server to use to attach to the process. If *Server* is zero, the engine will connect to the local process without using a process server.

CommandLine [in, optional]

Specifies the command line to execute to create the new process. If *CommandLine* is **NULL**, then no process is created and these methods attach to an existing process, as [AttachProcess](#) does.

CreateFlags [in]

Specifies the flags to use when creating the process. For details on these flags, see [DEBUG_CREATE_PROCESS_OPTIONS.CreateFlags](#).

ProcessId [in]

Specifies the process ID of the target process the debugger will attach to. If *ProcessId* is zero, the debugger will attach to the process it created from *CommandLine*.

AttachFlags [in]

Specifies the flags that control how the debugger attaches to the target process. For details on these flags, see [DEBUG_ATTACH_XXX](#).

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

This method is available only for live user-mode debugging.

If *CommandLine* is not **NULL** and *ProcessId* is not zero, then the engine will create the process in a suspended state. The engine will resume this newly created process after it successfully connects to the process specified in *ProcessId*.

Note The engine doesn't completely attach to the process until the [WaitForEvent](#) method has been called. Only after the process has generated an event -- for example, the create-process event -- does it become available in the debugger session.

For more information about creating and attaching to live user-mode targets, see [Live User-Mode Targets](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugClient::DetachProcesses method

The [DetachProcesses](#) method detaches the [debugger engine](#) from all [processes](#) in all targets, resuming all their [threads](#).

Syntax

```
C++  
HRESULT DetachProcesses();
```

Parameters

This method has no parameters.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

The targets must be running on Windows XP or a later version of Windows.

For more information about creating and attaching to live user-mode targets, see [Live User-Mode Targets](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

IDebugClient::DisconnectProcessServer method

The [DisconnectProcessServer](#) method disconnects the [debugger engine](#) from a process server.

Syntax

```
C++  
HRESULT DisconnectProcessServer(  
    [in] ULONG64 Server  
) ;
```

Parameters

Server [in]

Specifies the server from which to disconnect. This handle must have been previously returned by [ConnectProcessServer](#).

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

For more information about process servers and remote debugging, see [Process Servers, Kernel Connection Servers, and Smart Clients](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

IDebugClient::DispatchCallbacks method

The **DispatchCallbacks** method lets the [debugger engine](#) use the current thread for callbacks.

Syntax

C++
HRESULT DispatchCallbacks(
 [in] ULONG Timeout
) ;

Parameters

Timeout [in]

Specifies how many milliseconds to wait before this method will return. If *Timeout* is INFINITE, this method will not return until [ExitDispatch](#) is called or an error occurs.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful (ExitDispatch was used).
S_FALSE	<i>Timeout</i> milliseconds elapsed.

Remarks

This method returns when *Timeout* milliseconds have elapsed, [ExitDispatch](#) is called, or an error occurs.

Almost all client methods must be called from the thread in which the client was created; [callback objects](#) registered with the client are also called from this thread. When **DispatchCallbacks** is called the engine can use the current thread to make callback calls.

Client threads should call this method whenever possible to allow the callbacks to be called, unless the thread was the same thread used to start the debugger session, in which case the callbacks are called when [WaitForEvent](#) is called.

For more information about callbacks, see [Callbacks](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h or Winbase.h)

See also

[IDebugClient](#)
[IDebugClient2](#)
[IDebugClient3](#)
[IDebugClient4](#)
[IDebugClient5](#)
[ExitDispatch](#)
[WaitForEvent](#)
[FlushCallbacks](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugClient::EndSession method

The **EndSession** method ends the current debugger session.

Syntax

```
C++  
HRESULT EndSession(  
    [in] ULONG Flags  
) ;
```

Parameters

Flags [in]

Specifies how to end the session. *Flags* can be one of the following values:

Flag	Description
DEBUG_END_PASSIVE	Perform cleanup for the session.
DEBUG_END_ACTIVE_TERMINATE	Attempt to terminate all user-mode targets before performing cleanup for the session.
DEBUG_END_ACTIVE_DETACH	Attempt to disconnect from all targets before performing cleanup for the session.
DEBUG_END_REENTRANT	Perform only the cleanup that doesn't require acquiring locks. See Remarks section for details.
DEBUG_END_DISCONNECT	Do not end the session. Disconnect the client from the session and disable the client.
DEBUG_END_DISCONNECT	This flag is intended for when remote clients disconnect. It generates a server message about the disconnection.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

This method may be called at any time with *Flags* set to DEBUG_END_REENTRANT. If, for example, the application needs to exit but another thread is using the engine, this method can be used to perform as much cleanup as possible.

Using DEBUG_END_REENTRANT may leave the engine in an indeterminate state. If this flag is used, no subsequent calls should be made to the engine.

For more information about debugger sessions, see [Debugging Session and Execution Model](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugClient::ExitDispatch method

The **ExitDispatch** method causes the [DispatchCallbacks](#) method to return.

Syntax

```
C++  
HRESULT ExitDispatch(  
    [in] PDEBUG_CLIENT Client  
>;
```

Parameters

Client [in]

Specifies the client whose [DispatchCallbacks](#) method should return.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

This method is reentrant and may be called from any thread.

This method can be used to interrupt a thread waiting in [DispatchCallbacks](#).

For more information about callbacks, see [Callbacks](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugClient](#)
[IDebugClient2](#)
[IDebugClient3](#)
[IDebugClient4](#)
[IDebugClient5](#)
[DispatchCallbacks](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugClient::FlushCallbacks method

The **FlushCallbacks** method forces any remaining buffered output to be delivered to the [IDebugOutputCallbacks](#) object registered with this client.

Syntax

```
C++  
HRESULT FlushCallbacks();
```

Parameters

This method has no parameters.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

The engine sometimes merges compatible callback requests to reduce callback overhead; small pieces of output are collected into larger groups to reduce the number of [IDebugOutputCallbacks::Output](#) calls. Using **FlushCallbacks** is necessary for a client to guarantee that all pending callbacks have been processed at a particular point. For example, a caller can flush callbacks before starting a lengthy operation outside of the engine so that pending callbacks are not delayed until after the operation.

For more information about callbacks, see [Callbacks](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugClient](#)
[IDebugClient2](#)
[IDebugClient3](#)

IDebugClient::GetEventCallbacks method

The **GetEventCallbacks** method returns the event callbacks object registered with this client.

Syntax

```
C++
HRESULT GetEventCallbacks(
    [out] PDEBUG_EVENT_CALLBACKS *Callbacks
);
```

Parameters

Callbacks [out]

Receives an interface pointer to the event callbacks object registered with this client.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

Each client can have at most one [IDebugEventCallbacks](#) or [IDebugEventCallbacksWide](#) object registered with it for receiving [events](#).

If no event callbacks object is registered with the client, the value of *Callbacks* will be set to **NULL**.

The **IDebugEventCallbacks** interface extends the COM interface **IUnknown**. Before returning the **IDebugEventCallbacks** object specified by *Callbacks*, the engine calls its **IUnknown::AddRef** method. When this object is no longer needed, its **IUnknown::Release** method should be called.

For more information about callbacks, see [Callbacks](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugClient](#)
[IDebugClient2](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugClient::GetExitCode method

The **GetExitCode** method returns the exit code of the current process if that process has already run through to completion.

Syntax

```
C++  
HRESULT GetExitCode(  
    [out] PULONG Code  
) ;
```

Parameters

Code [out]

Receives the exit code of the process. If the process is still running, *Code* will be set to STILL_ACTIVE.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
S_FALSE	The process is still running.

Remarks

This method is available only for live user-mode debugging.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugClient::GetIdentity method

The **GetIdentity** method returns a string describing the computer and user this client represents.

Syntax

```
C++  
HRESULT GetIdentity(  
    [out, optional] PSTR    Buffer,  
    [in]          ULONG   BufferSize,  
    [out, optional] PULONG IdentitySize  
) ;
```

Parameters

Buffer [out, optional]

Specifies the buffer to receive the string. If *Buffer* is **NULL**, this information is not returned.

BufferSize [in]

Specifies the size of the buffer *Buffer*.

IdentitySize [out, optional]

Receives the size of the string. If *IdentitySize* is **NULL**, this information is not returned.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful
S_FALSE	The size of the string was greater than the size of the buffer, so it was truncated to fit into the buffer.

Remarks

The specific content of the string varies with the operating system. If the client is remotely connected, some network information may also be present.

For more information about client objects, see [Client Objects](#).

Requirements

Target platform

IDebugClient::GetInputCallbacks method

The **GetInputCallbacks** method returns the [input callbacks](#) object registered with this client.

Syntax

C++

```
HRESULT GetInputCallbacks(
    [out] PDEBUG_INPUT_CALLBACKS *Callbacks
);
```

Parameters

Callbacks [out]

Receives an interface pointer for the [IDebugInputCallbacks](#) object registered with the client.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

Each client can have at most one [IDebugInputCallbacks](#) object registered with it to receive requests for input.

If no **IDebugInputCallbacks** object is registered with the client, the value of *Callbacks* will be set to **NULL**.

The **IDebugInputCallbacks** interface extends the COM interface **IUnknown**. Before returning the **IDebugInputCallbacks** object specified by *Callbacks*, the engine calls its **IUnknown::AddRef** method. When this object is no longer needed, its **IUnknown::Release** method should be called.

For more information about callbacks, see [Callbacks](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugClient::GetKernelConnectionOptions method

The **GetKernelConnectionOptions** method returns the connection options for the current kernel target.

Syntax

C++

```
HRESULT GetKernelConnectionOptions(
    [out, optional] PSTR    Buffer,
    [in]          ULONG   BufferSize,
    [out, optional] PULONG OptionsSize
);
```

Parameters

Buffer [out, optional]

Specifies the buffer to receive the connection options.

BufferSize [in]

Specifies the size in characters of the buffer *Buffer*.

OptionsSize [out, optional]

Receives the size in characters of the connection options. If *OptionsSize* is **NULL**, this information is not returned.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
S_FALSE	The size of the string was greater than the size of the buffer, so it was truncated to fit into the buffer.
E_UNEXPECTED	The current target is not a standard live kernel target.

Remarks

This method is available only for live kernel targets that are not local and not connected through eXDI.

The connection options returned are the same options used to connect to the kernel.

For more information about connecting to live kernel-mode targets, see [Live Kernel-Mode Targets](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugClient::GetOtherOutputMask method

The **GetOtherOutputMask** method returns the output mask for another client.

Syntax

C++

```
HRESULT GetOtherOutputMask(
    [in] PDEBUG_CLIENT Client,
    [out] PULONG        Mask
);
```

Parameters

Client [in]

Specifies the client whose output mask is desired.

Mask [out]

Receives the output mask for the client. See [DEBUG_OUTPUT_XXX](#) for details on how to interpret this value.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

For an overview of output in the debugger engine, see [Input and Output](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugClient::GetOutputCallbacks method

The **GetOutputCallbacks** method returns the [output callbacks](#) object registered with the client.

Syntax

```
C++  
HRESULT GetOutputCallbacks(  
    [out] PDEBUG_OUTPUT_CALLBACKS *Callbacks  
) ;
```

Parameters

Callbacks [out]

Receives an interface pointer to the [IDebugOutputCallbacks](#) object registered with the client.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

Each client can have at most one [IDebugOutputCallbacks](#) or [IDebugOutputCallbacksWide](#) object registered with it for output.

If no output callbacks object is registered with the client, the value of *Callbacks* will be set to **NULL**.

The [IDebugOutputCallbacks](#) interface extends the COM interface [IUnknown](#). Before returning the [IDebugOutputCallbacks](#) object specified by *Callbacks*, the engine calls its [IUnknown::AddRef](#) method. When this object is no longer needed, its [IUnknown::Release](#) method should be called.

For more information about callbacks, see [Callbacks](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugClient::GetOutputMask method

The **GetOutputMask** method returns the output mask currently set for the client.

Syntax

```
C++  
HRESULT GetOutputMask(  
    [out] PULONG Mask  
) ;
```

Parameters

Mask [out]

Receives the output mask for the client. See [DEBUG_OUTPUT_XXX](#) for details on how to interpret this value.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

For an overview of output in the debugger engine, see [Input and Output](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugClient::GetProcessOptions method

The **GetProcessOptions** method retrieves the process options affecting the current process.

Syntax

```
C++  
HRESULT GetProcessOptions(  
    [out] PULONG Options  
) ;
```

Parameters

Options [out]

Receives a set of flags representing the process options for the current process. For details on these options, see [DEBUG_PROCESS_XXX](#).

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

This method is only available in live user-mode debugging.

Some of the process options are global options, others are specific to the current process.

For more information about creating and attaching to live user-mode targets, see [Live User-Mode Targets](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugClient::GetRunningProcessDescription method

The **GetRunningProcessDescription** method returns a description of the process that includes the executable image name, the service names, the MTS package names, and the command line.

Syntax

```
C++  
HRESULT GetRunningProcessDescription(  
    [in]           ULONG64 Server,  
    [in]           ULONG   SystemId,  
    [in]           ULONG   Flags,  
    [out, optional] PSTR   ExeName,  
    [in]           ULONG   ExeNameSize,  
    [out, optional] PULONG ActualExeNameSize,  
    [out, optional] PSTR   Description,  
    [in]           ULONG   DescriptionSize,  
    [out, optional] PULONG ActualDescriptionSize  
) ;
```

Parameters

Server [in]

Specifies the process server to query for the process description. If *Server* is zero, the engine will query information about the local process directly.

SystemId [in]

Specifies the process ID of the process whose description is desired.

Flags [in]

Specifies a bit-set containing options that affect the behavior of this method. *Flags* can contain the following bit flags:

Flag	Description
DEBUG_PROC_DESC_NO_PATHS	Return only file names without path names.
DEBUG_PROC_DESC_NO_SERVICES	Do not look up service names.
DEBUG_PROC_DESC_NO_MTS_PACKAGES	Do not look up MTS package names.
DEBUG_PROC_DESC_NO_COMMAND_LINE	Do not retrieve the command line.

ExeName [out, optional]

Receives the name of the executable file used to start the process. If *ExeName* is **NULL**, this information is not returned.

ExeNameSize [in]

Specifies the size in characters of the buffer *ExeNameSize*.

ActualExeNameSize [out, optional]

Receives the size in characters of the executable file name. If *ExeNameSize* is **NULL**, this information is not returned.

Description [out, optional]

Receives extra information about the process, including service names, MTS package names, and the command line. If *Description* is **NULL**, this information is not returned.

DescriptionSize [in]

Specifies the size in characters of the buffer *Description*.

ActualDescriptionSize [out, optional]

Receives the size in characters of the extra information. If *ActualDescriptionSize* is **NULL**, this information is not returned.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
S_FALSE	The method was successful. However, either <i>ExeNameSize</i> or <i>DescriptionSize</i> were smaller than the size of the respective string and the string was truncated to fit inside the buffer.

Remarks

This method is available only for live user-mode debugging.

For more information about creating and attaching to live user-mode targets, see [Live User-Mode Targets](#).

Requirements

Target platform

IDebugClient::GetRunningProcessSystemIdByExecutableName method

The **GetRunningProcessSystemIdByExecutableName** method searches for a process with a given executable file name and return its process ID.

Syntax

C++
HRESULT GetRunningProcessSystemIdByExecutableName(
 [in] ULONG64 Server,
 [in] PCSTR ExeName,
 [in] ULONG Flags,
 [out] PULONG Id
)

Parameters

Server [in]

Specifies the process server to search for the executable name. If *Server* is zero, the engine will search for the executable name among the processes running on the local computer.

ExeName [in]

Specifies the executable file name for which to search.

Flags [in]

Specifies a bit-set that controls how the executable name is matched. The following flags may be present:

Flag	Description
DEBUG_GET_PROC_FULL_MATCH	<i>ExeName</i> specifies the full path name of the executable file name. If this flag is not set, this method will not use path names when searching for the process.
DEBUG_GET_PROC_ONLY_MATCH	Require that only one process match the executable file name <i>ExeName</i> .

Id [out]Receives the process ID of the first process to match *ExeName*.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
S_FALSE	More than one process matched the executable file name in <i>ExeName</i> , and DEBUG_GET_PROC_ONLY_MATCH was set in <i>Flags</i> .
E_NOINTERFACE	No process matched the executable file name in <i>ExeName</i> .

Remarks

This method is available only for live user-mode debugging.

For more information about creating and attaching to live user-mode targets, see [Live User-Mode Targets](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugClient::GetRunningProcessSystemIds method

The **GetRunningProcessSystemIds** method returns the process IDs for each running process.

Syntax

```
C++
HRESULT GetRunningProcessSystemIds(
    [in]           ULONG64 Server,
    [out, optional] PULONG Ids,
    [in]           ULONG   Count,
    [out, optional] PULONG ActualCount
);
```

Parameters

Server [in]Specifies the process server to query for process IDs. If *Server* is zero, the engine will return the process IDs of the processes running on the local computer.*Ids* [out, optional]

Receives the process IDs. The size of this array is *Count*. If *Ids* is **NULL**, this information is not returned.

Count [in]

Specifies the number of process IDs the array *Ids* can hold.

ActualCount [out, optional]

Receives the actual number of process IDs returned in *Ids*.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

This method is available only for live user-mode debugging.

For more information about creating and attaching to live user-mode targets, see [Live User-Mode Targets](#).

Requirements

Target platform

IDebugClient::OpenDumpFile method

The **OpenDumpFile** method opens a dump file as a debugger target.

Syntax

C++

```
HRESULT OpenDumpFile(
    [in] PCSTR DumpFile
);
```

Parameters

DumpFile [in]

Specifies the name of the dump file to open. *DumpFile* must include the file name extension. *DumpFile* can include a relative or absolute path; relative paths are relative to the directory in which the debugger was started. *DumpFile* can have the form of a file URL, starting with "file://". If *DumpFile* specifies a cabinet (.cab) file, the cabinet file is searched for the first file with extension .kdmp, then .hdmp, then .mdmp, and finally .dmp.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

The Unicode version of this method is [OpenDumpFileWide](#).

Note The engine doesn't completely attach to the dump file until the [WaitForEvent](#) method has been called. When a dump file is created from a process or kernel, information about the last event is stored in the dump file. After the dump file is opened, the next time execution is attempted, the engine will generate this event for the event callbacks. Only then does the dump file become available in the debugging session.

For more information about crash dump files, see [Dump-File Targets](#).

IDebugClient::OutputIdentity method

The **OutputIdentity** method formats and outputs a string describing the computer and user this client represents.

Syntax

C++
HRESULT OutputIdentity(
 [in] ULONG OutputControl,
 [in] ULONG Flags,
 [in] PCSTR Format
) ;

Parameters

OutputControl [in]

Specifies where to send the output. For possible values, see [DEBUG_OUTCTL_XXX](#).

Flags [in]

Set to zero.

Format [in]

Specifies a format string similar to the **printf** format string. However, this format string must only contain one formatting directive, **%s**, which will be replaced by a description of the computer and user this client represents.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

The specific content of the string varies with the operating system. If the client is remotely connected, some network information may also be present.

For more information about client objects, see [Client Objects](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugClient::OutputServers method

The **OutputServers** method lists the servers running on a given computer.

Syntax

C++
HRESULT OutputServers(
 [in] ULONG OutputControl,
 [in] PCSTR Machine,
 [in] ULONG Flags
) ;

Parameters

OutputControl [in]

Specifies the output control to use while outputting the servers. For possible values, see [DEBUG_OUTCTL_XXX](#).

Machine [in]

Specifies the name of the computer whose servers will be listed. *Machine* has the following form:

\\computername

Flags [in]

Specifies a bit-set that determines which servers to output. The possible bit flags are:

Flag	Description
DEBUG_SERVERS_DEBUGGER	Output the debugging servers on the computer.
DEBUG_SERVERS_PROCESS	Output the process servers on the computer.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

For more information about remote debugging, see [Remote Debugging](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugClient::RemoveProcessOptions method

The **RemoveProcessOptions** method removes process options from those options that affect the current process.

Syntax

C++

```
HRESULT RemoveProcessOptions(  
    [in] ULONG Options  
) ;
```

Parameters

Options [in]

Specifies the process options to remove from those affecting the current process. For details on these options, see [DEBUG_PROCESS_XXX](#).

Return value

Return code	Description
S_OK	The method was successful.

This method may also return error values. See [Return Values](#) for more details.

Remarks

This method is available only in live user-mode debugging.

Some of the process options are global options, others are specific to the current process.

If any process options are modified, the engine will notify the event callbacks by calling their [IDebugEventCallbacks::ChangeEngineState](#) method with the DEBUG_CES_PROCESS_OPTIONS flag set.

For more information about creating and attaching to live user-mode targets, see [Live User-Mode Targets](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugClient::SetEventCallbacks method

The **SetEventCallbacks** method registers an event callbacks object with this client.

Syntax

```
C++  
HRESULT SetEventCallbacks(  
    [in, optional] PDEBUG_EVENT_CALLBACKS Callbacks  
)
```

Parameters

Callbacks [in, optional]

Specifies the interface pointer to the event callbacks object to register with this client.

Return value

Depending on the implementation of the method [IDebugEventCallbacks::GetInterestMask](#) in the object specified by *Callbacks*, other values may be returned, as described in the Remarks section.

Return code	Description
S_OK	The method was successful.

Remarks

If the value of *Callbacks* is not **NULL**, the method [IDebugEventCallbacks::GetInterestMask](#) is called. If the return value is not S_OK, **SetEventCallbacks** and **SetEventCallbacksWide** have no effect and they return this value.

Each client can have at most one [IDebugEventCallbacks](#) or [IDebugEventCallbacksWide](#) object registered with it for receiving [events](#).

The **IDebugEventCallbacks** interface extends the COM interface **IUnknown**. When **SetEventCallbacks** and **SetEventCallbacksWide** are successful, they call the **IUnknown::AddRef** method of the object specified by *Callbacks*. The **IUnknown::Release** method of this object will be called the next time **SetEventCallbacks** or **SetEventCallbacksWide** is called on this client, or when this client is deleted.

For more information about callbacks, see [Callbacks](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugClient::SetInputCallbacks method

The **SetInputCallbacks** method registers an [input callbacks](#) object with the client.

Syntax

```
C++  
HRESULT SetInputCallbacks(  
    [in, optional] PDEBUG_INPUT_CALLBACKS Callbacks  
)
```

Parameters

Callbacks [in, optional]

Specifies the interface pointer to the input callbacks object to register with this client.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

Each client can have at most one [IDebugInputCallbacks](#) object registered with it to receive requests for input.

The [IDebugInputCallbacks](#) interface extends the COM interface [IUnknown](#). [SetInputCallbacks](#) will call the [IUnknown::AddRef](#) method of the object specified by *Callbacks*. The [IUnknown::Release](#) method of this interface will be called the next time [SetInputCallbacks](#) is called on this client, or when this client is deleted.

Requirements

IDebugClient::SetKernelConnectionOptions method

The [SetKernelConnectionOptions](#) method updates some of the connection options for a live kernel target.

Syntax

```
C++  
HRESULT SetKernelConnectionOptions(  
    [in] PCSTR Options  
) ;
```

Parameters

Options [in]

Specifies the connection options to update. The possible values are:

Value	Description
"resync"	Re-synchronize the connection between the debugger engine and the kernel. For more information, see Synchronizing with the Target Computer .
"cycle_speed"	For kernel connections through a COM port, cycle through the supported baud rates; for other connections, do nothing. For more information, see CTRL+A (Toggle Baud Rate) .

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
E_UNEXPECTED	The current target is not a live (non-local) kernel target.

Remarks

This method is available only for live kernel targets that are not local and not connected through eXDI. This method is reentrant.

For more information about connecting to live kernel-mode targets, see [Live Kernel-Mode Targets](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugClient::SetOtherOutputMask method

The **SetOtherOutputMask** method sets the output mask for another client.

Syntax

```
C++  
HRESULT SetOtherOutputMask(  
    [in] PDEBUG_CLIENT Client,  
    [in] ULONG Mask  
) ;
```

Parameters

Client [in]

Specifies the client whose output mask will be set.

Mask [in]

Specifies the new output mask for the client. See [DEBUG_OUTPUT_XXX](#) for a description of the possible values for *Mask*.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

For an overview of output in the debugger engine, see [Input and Output](#).

Requirements

Target platform

IDebugClient::SetOutputCallbacks method

The **SetOutputCallbacks** method registers an [output callbacks](#) object with this client.

Syntax

```
C++
HRESULT SetOutputCallbacks(
    [in, optional] PDEBUG_OUTPUT_CALLBACKS Callbacks
);
```

Parameters

Callbacks [in, optional]

Specifies the interface pointer to the output callbacks object to register with this client.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

Each client can have at most one [IDebugOutputCallbacks](#) or [IDebugOutputCallbacks](#) object registered with it for output.

The **IDebugOutputCallbacks** interface extends the COM interface **IUnknown**. **SetOutputCallbacks** and **SetOutputCallbacksWide** call the **IUnknown::AddRef** method in the object specified by *Callbacks*. The **IUnknown::Release** method of this interface will be called the next time **SetOutputCallbacks** or **SetOutputCallbacksWide** is called on this client, or when this client is deleted.

For more information about callbacks, see [Callbacks](#).

Requirements

Target platform

IDebugClient::SetOutputMask method

The **SetOutputMask** method sets the output mask for the client.

Syntax

```
C++
```

```
HRESULT SetOutputMask(
    [in] ULONG Mask
);
```

Parameters

Mask [in]

Specifies the new output mask for the client. See [DEBUG_OUTPUT_XXX](#) for a description of the possible values for *Mask*.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

For an overview of output in the debugger engine, see [Input and Output](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugClient](#)
[IDebugClient2](#)

IDebugClient::SetProcessOptions method

The **SetProcessOptions** method sets the process options affecting the current process.

Syntax

```
C++
HRESULT SetProcessOptions(
    [in] ULONG Options
);
```

Parameters

Options [in]

Specifies a set of flags that will become the new process options for the current process. For details on these options, see [DEBUG_PROCESS_XXX](#).

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

This method is available only in live user-mode debugging.

Some of the process options are global options, others are specific to the current process.

If any process options are modified, the engine will notify the event callbacks by calling their [IDebugEventCallbacks::ChangeEngineState](#) method with the DEBUG_CES_PROCESS_OPTIONS flag set.

For more information about creating and attaching to live user-mode targets, see [Live User-Mode Targets](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

IDebugClient::StartProcessServer method

The StartProcessServer method starts a process server.

Syntax

C++

```
HRESULT StartProcessServer(
    [in]          ULONG Flags,
    [in]          PCSTR Options,
    [in, optional] PVOID Reserved
);
```

Parameters

Flags [in]

Specifies the class of the targets that will be available through the process server. This must be set to DEBUG_CLASS_USER_WINDOWS.

Options [in]

Specifies the connections options for this process server. These are the same options given to the -t option of the DbgSrv command line. For details on the syntax of this string, see [Activating a Process Server](#).

Reserved [in, optional]

Set to NULL.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

The process server that is started will be accessible by remote clients through the transport specified in the Options parameter.

To stop the process server from the smart client, use the [EndProcessServer](#) method. To shut down the process server from the computer that it is running on, use Task Manager to end the process. If the instance of the debugger engine that used StartProcessServer is still running, it can use [Execute](#) to issue the debugger command [.endsrv](#), which will end the process server (this is an exception to the usual behavior of [.endsrv](#), which generally does not affect process servers).

For more information about process servers and remote debugging, see [Process Servers, Kernel Connection Servers, and Smart Clients](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugClient::StartServer method

The StartServer method starts a debugging server.

Syntax

C++
HRESULT StartServer(
 [in] PCSTR Options
) ;

Parameters

Options [in]

Specifies the connections options for this server. These are the same options given to the .server debugger command or the WinDbg and CDB -server command-line option. For details on the syntax of this string, see [Activating a Debugging Server](#).

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

The server that is started will be accessible by other [debuggers](#) through the transport specified in the *Options* parameter.

For more information about debugging servers, see Debugging Server and Debugging Client.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

IDebugClient::TerminateProcesses method

The **TerminateProcesses** method attempts to terminate all [processes](#) in all targets.

Syntax

```
C++  
HRESULT TerminateProcesses();
```

Parameters

This method has no parameters.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

Only live user-mode processes are terminated by this method. For other targets, the target is detached from the debugger without terminating.

For more information about creating and attaching to live user-mode targets, see [Live User-Mode Targets](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugClient::WriteDumpFile method

The **WriteDumpFile** method creates a user-mode or kernel-modecrash dump file.

Syntax

```
C++  
HRESULT WriteDumpFile(  
    [in] PCSTR DumpFile,  
    [in] ULONG Qualifier  
>;
```

Parameters

DumpFile [in]

Specifies the name of the dump file to create. *DumpFile* must include the file name extension. *DumpFile* can include a relative or absolute path; relative paths are relative to the directory in which the debugger was started.

Qualifier [in]

Specifies the type of dump file to create. For possible values, see [DEBUG_DUMP_XXX](#).

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

To specify the formatting of the file and--for user-mode minidumps--the information to include in the file, use [WriteDumpFile2](#) or [WriteDumpFileWide](#).

For more information about crash dump files, see [Dump-File Targets](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugClient2 interface

Members

The IDebugClient2 interface inherits from [IDebugClient](#). IDebugClient2 also has these types of members:

- [Methods](#)

Methods

The IDebugClient2 interface has these methods.

Method	Description
AbandonCurrentProcess	Removes the current process from the debugger engine's process list without detaching or terminating the process.
AddDumpInformationFile	Registers additional files containing supporting information that will be used when opening a dump file.
DetachCurrentProcess	Detaches the debugger engine from the current process, resuming all its threads.
EndProcessServer	Requests that a process server be shut down.
IsKernelDebuggerEnabled	Checks whether kernel debugging is enabled for the local kernel.
TerminateCurrentProcess	Attempts to terminate the current process.
WaitForProcessServerEnd	Waits for a local process server to exit.
WriteDumpFile2	Creates a user-mode or kernel-mode crash dump file.

Requirements

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugClient](#)
[IDebugClient3](#)

[IDebugClient4](#)
[IDebugClient5](#)

[Send comments about this topic to Microsoft](#)

IDebugClient2::AbandonCurrentProcess method

The **AbandonCurrentProcess** method removes the *current process* from the debugger engine's process list without detaching or terminating the process.

Syntax

C++

```
HRESULT AbandonCurrentProcess();
```

Parameters

This method has no parameters.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

This method is only available for live user-mode debugging. The target must be running on Windows XP or a later version of Windows.

Windows will continue to consider this process as being debugged, and so the process will remain suspended. This method allows the debugger to be shut down and a new debugger to attach to the process. See [Live User-Mode Targets](#) and [Re-attaching to the Target Application](#) for more information.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

IDebugClient2::AddDumpInformationFile method

The **AddDumpInformationFile** method registers additional files containing supporting information that will be used when opening a dump file. The Unicode version of this method is [AddDumpInformationFileWide](#).

Syntax

C++

```
HRESULT AddDumpInformationFile(
    [in] PCSTR InfoFile,
    [in] ULONG Type
);
```

Parameters

InfoFile [in]

Specifies the name of the file containing the supporting information.

Type [in]

Specifies the type of the file *InfoFile*. Currently, only files containing paging file information are supported, and *Type* must be set to DEBUG_DUMP_FILE_PAGE_FILE_DUMP.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

If supporting information is to be used when opening a dump file, this method or [AddDumpInformationFileWide](#) must be called before [OpenDumpFile](#) is called. If a session has already started, this method cannot be used.

For more information about crash dump files, see [Dump File Targets](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

IDebugClient2::DetachCurrentProcess method

The **DetachCurrentProcess** method detaches the [debugger engine](#) from the current process, resuming all its [threads](#).

Syntax

C++

```
HRESULT DetachCurrentProcess();
```

Parameters

This method has no parameters.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

The target must be running on Windows XP or a later versions of Windows.

For more information about creating and attaching to live user-mode targets, see [Live User-Mode Targets](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

IDebugClient2::EndProcessServer method

The **EndProcessServer** method requests that a process server be shut down.

Syntax

```
C++
HRESULT EndProcessServer(
    [in] ULONG64 Server
);
```

Parameters

Server [in]

Specifies the process server to shut down. This handle must have been previously returned by [ConnectProcessServer](#).

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

For more information about process servers and remote debugging, see [Process Servers, Kernel Connection Servers, and Smart Clients](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugClient2](#)
[IDebugClient3](#)

© 2016 Microsoft. All rights reserved.

IDebugClient2::IsKernelDebuggerEnabled method

The **IsKernelDebuggerEnabled** method checks whether kernel debugging is enabled for the local kernel.

Syntax

C++

```
HRESULT IsKernelDebuggerEnabled();
```

Parameters

This method has no parameters.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	Kernel debugging is enabled for the local kernel.
S_FALSE	Kernel debugging is not enabled for the local kernel.

Remarks

Kernel debugging is available for the local computer if the computer was booted by using the **/debug** boot switch. In some Windows installations, [local kernel debugging](#) is supported when other switches--such as **/debugport**--are used, but this is not a guaranteed feature of Windows and should not be relied on. For more information about kernel debugging on a single computer, see [Performing Local Kernel Debugging](#).

For more information about connecting to live kernel-mode targets, see [Live Kernel-Mode Targets](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugClient2](#)
[IDebugClient3](#)
[IDebugClient4](#)
[IDebugClient5](#)
[AttachKernel](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugClient2::TerminateCurrentProcess method

The **TerminateCurrentProcess** method attempts to terminate the current process.

Syntax

C++

```
HRESULT TerminateCurrentProcess();
```

Parameters

This method has no parameters.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

Only live user-modeprocesses are terminated by this method. For other targets, the target is detached from the [debugger engine](#) without terminating.

For more information about creating and attaching to live user-mode targets, see [Live User-Mode Targets](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

IDebugClient2::WaitForProcessServerEnd method

The **WaitForProcessServerEnd** method waits for a local process server to exit.

Syntax

```
C++
HRESULT WaitForProcessServerEnd(
    [in] ULONG Timeout
);
```

Parameters

Timeout [in]

Specifies how long in milliseconds to wait for a process server to exit. If *Timeout* is INFINITE, this method will not return until a process server has ended.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
S_FALSE	A time-out occurred -- <i>Timeout</i> milliseconds passed without a local process server exiting.

Remarks

This method will only wait for the first local process server to end. After a process server has ended, subsequent calls to this method will return immediately.

For more information about process servers and remote debugging, see [Process Servers, Kernel Connection Servers, and Smart Clients](#).

The constant INFINITE is defined in Winbase.h.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h or Winbase.h)

See also

IDebugClient2::WriteDumpFile2 method

The **WriteDumpFile2** method creates a user-mode or kernel-mode crash dump file.

Syntax

```
C++
HRESULT WriteDumpFile2(
    [in]          PCSTR DumpFile,
    [in]          ULONG Qualifier,
    [in]          ULONG FormatFlags,
    [in, optional] PCSTR Comment
);
```

Parameters

DumpFile [in]

Specifies the name of the dump file to create. *DumpFile* must include the file name extension. *DumpFile* can include a relative or absolute path; relative paths are relative to the directory in which the debugger was started.

Qualifier [in]

Specifies the type of dump file to create. For possible values, see [DEBUG_DUMP_XXX](#).

FormatFlags [in]

Specifies flags that determine the format of the dump file and--for user-mode minidumps--what information to include in the file. For details, see [DEBUG_FORMAT_XXX](#).

Comment [in, optional]

Specifies a comment string to be included in the crash dump file. This string is displayed in the debugger console when the dump file is loaded. Some dump file formats do not support the storing of comment strings.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

For more information about crash dump files, see [Dump-File Targets](#).

Requirements

Target platform
Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugClient2](#)

IDebugClient3 interface

Members

The IDebugClient3 interface inherits from [IDebugClient2](#). IDebugClient3 also has these types of members:

- [Methods](#)

Methods

The IDebugClient3 interface has these methods.

Method	Description
CreateProcessAndAttachWide	Creates a process from a specified command line, then attaches to another user-mode process.
CreateProcessWide	Creates a process from the specified command line.
GetRunningProcessDescriptionWide	Returns a description of the process that includes the executable image name, the service names, the MTS package names, and the command line.
GetRunningProcessSystemIdByExecutableNameWide	Searches for a process with a given executable file name and return its process ID.

Requirements

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugClient2](#)
[IDebugClient4](#)
[IDebugClient5](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugClient3::CreateProcessAndAttachWide method

The **CreateProcessAndAttachWide** method creates a process from a specified command line, then attach to another user-mode process. The created process is suspended and only allowed to execute when the attach has completed. This allows rough synchronization when debugging both, client and server processes.

Syntax

```
C++
HRESULT CreateProcessAndAttachWide(
    [in]           ULONG64 Server,
    [in, optional] PWSTR CommandLine,
    [in]           ULONG   CreateFlags,
    [in]           ULONG   ProcessId,
    [in]           ULONG   AttachFlags
);
```

Parameters

Server [in]

Specifies the process server to use to attach to the process. If *Server* is zero, the engine will connect to the local process without using a process server.

CommandLine [in, optional]

Specifies the command line to execute to create the new process. If *CommandLine* is NULL, then no process is created and these methods attach to an existing process, as [AttachProcess](#) does.

CreateFlags [in]

Specifies the flags to use when creating the process. For details on these flags, see [DEBUG CREATE PROCESS OPTIONS](#).*CreateFlags*.

ProcessId [in]

Specifies the process ID of the target process the debugger will attach to. If *ProcessId* is zero, the debugger will attach to the process it created from *CommandLine*.

AttachFlags [in]

Specifies the flags that control how the debugger attaches to the target process. For details on these flags, see [DEBUG_ATTACH_XXX](#).

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

This method is available only for live user-mode debugging.

If *CommandLine* is not **NULL** and *ProcessId* is not zero, then the engine will create the process in a suspended state. The engine will resume this newly created process after it successfully connects to the process specified in *ProcessId*.

The engine does not completely attach to the process until the [WaitForEvent](#) method has been called. Only after the process has generated an event -- for example, the create-process event -- does it become available in the debugger session.

For more information about creating and attaching to live user-mode targets, see [Live User-Mode Targets](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugClient3::CreateProcessWide method

The **CreateProcessWide** method creates a process from the specified command line.

Syntax

C++

```
HRESULT CreateProcessWide(
    [in] ULONG64 Server,
    [in] PWSTR CommandLine,
    [in] ULONG CreateFlags
);
```

Parameters

Server [in]

Specifies the process server to use when attaching to the process. If *Server* is zero, the engine will create a local process without using a process server.

CommandLine [in]

Specifies the command line to execute to create the new process. The **CreateProcessWide** method might modify the contents of the string that you supply in this parameter. Therefore, this parameter cannot be a pointer to read-only memory (such as a const variable or a literal string). Passing a constant string in this parameter can lead to an access violation.

CreateFlags [in]

Specifies the flags to use when creating the process. For details on these flags, see the **CreateFlags** member of the [DEBUG_CREATE_PROCESS_OPTIONS](#) structure.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

This method is available only for live user-mode debugging.

If *CreateFlags* contains either of the flags DEBUG_PROCESS or DEBUG_ONLY_THIS_PROCESS, the engine also attaches to the newly created process. This behavior is similar to that of [CreateProcessAndAttach2](#) when its argument *ProcessId* is set to zero.

For more information about creating and attaching to live user-mode targets, see [Live User-Mode Targets](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugClient3::GetRunningProcessDescriptionWide method

The **GetRunningProcessDescriptionWide** method returns a description of the process that includes the executable image name, the service names, the MTS package names, and the command line.

Syntax

C++

```
HRESULT GetRunningProcessDescriptionWide(
    [in]           ULONG64 Server,
    [in]           ULONG   SystemId,
    [in]           ULONG   Flags,
    [out, optional] PWSTR   ExeName,
    [in]           ULONG   ExeNameSize,
    [out, optional] PULONG  ActualExeNameSize,
    [out, optional] PWSTR   Description,
    [in]           ULONG   DescriptionSize,
    [out, optional] PULONG  ActualDescriptionSize
);
```

Parameters

Server [in]

Specifies the process server to query for the process description. If *Server* is zero, the engine will query information about the local process directly.

SystemId [in]

Specifies the process ID of the process whose description is desired.

Flags [in]

Specifies a bit-set containing options that affect the behavior of this method. *Flags* can contain the following bit flags:

Flag	Description
DEBUG_PROC_DESC_NO_PATHS	Return only file names without path names.
DEBUG_PROC_DESC_NO_SERVICES	Do not look up service names.
DEBUG_PROC_DESC_NO_MTS_PACKAGES	Do not look up MTS package names.
DEBUG_PROC_DESC_NO_COMMAND_LINE	Do not retrieve the command line.

ExeName [out, optional]

Receives the name of the executable file used to start the process. If *ExeName* is **NULL**, this information is not returned.

ExeNameSize [in]

Specifies the size in characters of the buffer *ExeNameSize*.

ActualExeNameSize [out, optional]

Receives the size in characters of the executable file name. If *ExeNameSize* is **NULL**, this information is not returned.

Description [out, optional]

Receives extra information about the process, including service names, MTS package names, and the command line. If *Description* is **NULL**, this information is not returned.

DescriptionSize [in]

Specifies the size in characters of the buffer *Description*.

ActualDescriptionSize [out, optional]

Receives the size in characters of the extra information. If *ActualDescriptionSize* is **NULL**, this information is not returned.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
S_FALSE	The method was successful. However, either <i>ExeNameSize</i> or <i>DescriptionSize</i> were smaller than the size of the respective string and the string was truncated to fit inside the buffer.

Remarks

This method is available only for live user-mode debugging.

For more information about creating and attaching to live user-mode targets, see [Live User-Mode Targets](#).

Requirements**Target platform**

Header Dbgeng.h (include Dbgeng.h)

IDebugClient3::GetRunningProcessSystemIdByExecutableNameWide method

The **GetRunningProcessSystemIdByExecutableNameWide** method searches for a process with a given executable file name and return its process ID.

Syntax

```
C++
HRESULT GetRunningProcessSystemIdByExecutableNameWide(
    [in]    ULONG64 Server,
    [in]    PCWSTR ExeName,
    [in]    ULONG   Flags,
    [out]   PULONG  Id
);
```

Parameters

Server [in]

Specifies the process server to search for the executable name. If *Server* is zero, the engine will search for the executable name among the processes running on the local computer.

ExeName [in]

Specifies the executable file name for which to search.

Flags [in]

Specifies a bit-set that controls how the executable name is matched. The following flags may be present:

Flag	Description
DEBUG_GET_PROC_FULL_MATCH	<i>ExeName</i> specifies the full path name of the executable file name. If this flag is not set, this method will not use path names when searching for the process.
DEBUG_GET_PROC_ONLY_MATCH	Require that only one process match the executable file name <i>ExeName</i> .

Id [out]

Receives the process ID of the first process to match *ExeName*.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
S_FALSE	More than one process matched the executable file name in <i>ExeName</i> , and DEBUG_GET_PROC_ONLY_MATCH was set in <i>Flags</i> .
E_NOINTERFACE	No process matched the executable file name in <i>ExeName</i> .

Remarks

This method is available only for live user-mode debugging.

For more information about creating and attaching to live user-mode targets, see [Live User-Mode Targets](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugClient4 interface

Members

The **IDebugClient4** interface inherits from [IDebugClient3](#). **IDebugClient4** also has these types of members:

- [Methods](#)

Methods

The **IDebugClient4** interface has these methods.

Method	Description
AddDumpInformationFileWide	Registers additional files containing supporting information that will be used when opening a dump file.
GetDumpFile	Describes the files containing supporting information that were used when opening the current dump target. (ANSI version)
GetDumpFileWide	Describes the files containing supporting information that were used when opening the current dump target. (Unicode version)
GetNumberDumpFiles	Returns the number of files containing supporting information that were used when opening the current dump target.
OpenDumpFileWide	Opens a dump file as a debugger target.
WriteDumpFileWide	Creates a user-mode or kernel-mode crash dump file.

Requirements

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugClient3](#)
[IDebugClient5](#)

[Send comments about this topic to Microsoft](#)

IDebugClient4::AddDumpInformationFileWide method

The **AddDumpInformationFileWide** method registers additional files containing supporting information that will be used when opening a [dump file](#). The ASCII version of this method is [AddDumpInformationFile](#).

Syntax

```
C++  
HRESULT AddDumpInformationFileWide(  
    [in, optional] PCWSTR FileName,  
    [in]          ULONG64 FileHandle,  
    [in]          ULONG    Type  
) ;
```

Parameters

FileName [in, optional]

Specifies the name of the file containing the supporting information. If *FileHandle* is not zero, *FileName* is used only for informational purposes.

FileHandle [in]

Specifies the handle of the file containing the supporting information. If *FileHandle* is zero, the file named in *FileName* is used.

Type [in]

Specifies the type of the file in *FileName* or *FileHandle*. Currently, only files containing paging file information are supported, and *Type* must be set to DEBUG_DUMP_FILE_PAGE_FILE_DUMP.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

If supporting information is to be used when opening a dump file, this method or [AddDumpInformationFile](#) must be called before [OpenDumpFile](#) is called. If a session has already started, this method cannot be used.

For more information about crash dump files, see [Dump-File Targets](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugClient4::GetDumpFile method

The **GetDumpFile** method describes the files containing supporting information that were used when opening the current dump target.

Syntax

```
C++  
HRESULT GetDumpFile(  
    [in]           ULONG     Index,  
    [out, optional] PSTR      Buffer,  
    [in]           ULONG     BufferSize,  
    [out, optional] PULONG    NameSize,  
    [out, optional] PULONG64  Handle,  
    [out]          PULONG    Type  
) ;
```

Parameters

Index [in]

Specifies which file to describe. *Index* can take values between zero and the number of files minus one; the number of files can be found by using [GetNumberDumpFiles](#).

Buffer [out, optional]

Receives the file name. If *Buffer* is **NULL**, this information is not returned.

BufferSize [in]

Specifies the size in characters of the buffer *Buffer*.

NameSize [out, optional]

Receives the size of the file name. If *NameSize* is **NULL**, this information is not returned.

Handle [out, optional]

Receives the file handle of the file. If *Handle* is **NULL**, this information is not returned.

Type [out]

Receives the type of the file.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

For more information about crash dump files, see [Dump-File Targets](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugClient4::GetDumpFileWide method

The `GetDumpFileWide` method describes the files containing supporting information that were used when opening the current dump target.

Syntax

C++

```
HRESULT GetDumpFileWide(
    [in]           ULONG      Index,
    [out, optional] PWSTR     Buffer,
    [in]           ULONG      BufferSize,
    [out, optional] PULONG    NameSize,
    [out, optional] PULONG64  Handle,
    [out]          PULONG    Type
);
```

Parameters

Index [in]

Specifies which file to describe. *Index* can take values between zero and the number of files minus one; the number of files can be found by using [GetNumberDumpFiles](#).

Buffer [out, optional]

Receives the file name. If *Buffer* is **NULL**, this information is not returned.

BufferSize [in]

Specifies the size in characters of the buffer *Buffer*.

NameSize [out, optional]

Receives the size of the file name. If *NameSize* is **NULL**, this information is not returned.

Handle [out, optional]

Receives the file handle of the file. If *Handle* is **NULL**, this information is not returned.

Type [out]

Receives the type of the file.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

For more information about crash dump files, see [Dump-File Targets](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

IDebugClient4::GetNumberDumpFiles method

The **GetNumberDumpFiles** method returns the number of files containing supporting information that were used when opening the current dump target.

Syntax

C++
HRESULT GetNumberDumpFiles(
 [out] PULONG Number
);

Parameters

Number [out]

Receives the number of files.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

For more information about crash dump files, see [Dump-File Targets](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugClient4](#)

IDebugClient4::OpenDumpFileWide method

The **OpenDumpFileWide** method opens a dump file as a debugger target.

Syntax

C++

```
HRESULT OpenDumpFileWide(
    [in, optional] PCWSTR FileName,
    [in]           ULONG64 FileHandle
);
```

Parameters

FileName [in, optional]

Specifies the name of the dump file to open -- unless *FileHandle* is not zero, in which case *FileName* is used only when the engine is queried for the name of the dump file. *FileName* must include the file name extension. *FileName* can include a relative or absolute path; relative paths are relative to the directory in which the debugger was started. *FileName* can also be in the form of a file URL, starting with "file://". If *FileName* specifies a cabinet (.cab) file, the cabinet file is searched for the first file with extension .kdmp, then .hdmp, then .mdmp, and finally .dmp.

FileHandle [in]

Specifies the file handle of the dump file to open. If *FileHandle* is zero, *FileName* is used to open the dump file. Otherwise, if *FileName* is not **NULL**, the engine returns it when queried for the name of the dump file. If *FileHandle* is not zero and *FileName* is **NULL**, the engine will return <**HandleOnly**> for the file name.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

The ASCII version of this method is [OpenDumpFile](#).

Note The engine doesn't completely attach to the dump file until the [WaitForEvent](#) method has been called. When a dump file is created from a process or kernel, information about the last event is stored in the dump file. After the dump file is opened, the next time execution is attempted, the engine will generate this event for the event callbacks. Only then does the dump file become available in the debugging session.

For more information about crash dump files, see [Dump-File Targets](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugClient4::WriteDumpFileWide method

The **WriteDumpFileWide** method creates a user-mode or kernel-modecrash dump file.

Syntax

```
C++  
HRESULT WriteDumpFileWide(  
    [in, optional] PCWSTR FileName,  
    [in]          ULONG64 FileHandle,  
    [in]          ULONG Qualifier,  
    [in]          ULONG FormatFlags,  
    [in, optional] PCWSTR Comment  
) ;
```

Parameters

FileName [in, optional]

Specifies the name of the dump file to create. *FileName* must include the file name extension. *FileName* can include a relative or absolute path; relative paths are relative to the directory in which the debugger was started. If *FileHandle* is not **NULL**, *FileName* is ignored (except when writing status messages to the debugger console).

FileHandle [in]

Specifies the file handle of the file to write the crash dump to. If *FileHandle* is **NULL**, the file specified in *FileName* is used instead.

Qualifier [in]

Specifies the type of dump to create. For possible values, see [DEBUG_DUMP_XXX](#).

FormatFlags [in]

Specifies flags that determine the format of the dump file and--for user-mode minidumps--what information to include in the file. For details, see [DEBUG_FORMAT_XXX](#).

Comment [in, optional]

Specifies a comment string to be included in the crash dump file. This string is displayed in the debugger console when the dump file is loaded.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

For more information about crash dump files, see [Dump-File Targets](#).

Requirements

Target platform

IDebugClient5 interface

Members

The **IDebugClient5** interface inherits from [IDebugClient4](#). **IDebugClient5** also has these types of members:

- [Methods](#)

Methods

The **IDebugClient5** interface has these methods.

Method	Description
AttachKernelWide	Connects the debugger engine to a kernel target.
ConnectProcessServerWide	Connects to a process server.
CreateProcess2	Executes the given command to create a new process. (ANSI version)
CreateProcess2Wide	Executes the given command to create a new process. (Unicode version)
CreateProcessAndAttach2	Creates a process from a specified command line, then attach to that process or another user-mode process. (ANSI version)
CreateProcessAndAttach2Wide	Creates a process from a specified command line, then attach to that process or another user-mode process. (Unicode version)
GetEventCallbacksWide	Returns the event callbacks object registered with this client.
GetIdentityWide	Returns a string describing the computer and user this client represents.
GetKernelConnectionOptionsWide	Returns the connection options for the current kernel target.
GetNumberEventCallbacks	Returns the number of event callbacks that are interested in the given events.
GetNumberInputCallbacks	Returns the number of input callbacks registered over all clients.
GetNumberOutputCallbacks	Returns the number of output callbacks registered over all clients.
GetOutputCallbacksWide	Returns the output callbacks object registered with the client.
GetOutputLinePrefixWide	
GetQuitLockString	
GetQuitLockStringWide	
OutputIdentityWide	Formats and outputs a string describing the computer and user this client represents.
OutputServersWide	Lists the servers running on a given computer.
PopOutputLinePrefix	
PushOutputLinePrefix	
PushOutputLinePrefixWide	
SetEventCallbacksWide	Registers an event callbacks object with this client.
SetKernelConnectionOptionsWide	Updates some of the connection options for a live kernel target.
SetOutputCallbacksWide	Registers an output callbacks object with this client.
SetOutputLinePrefixWide	
SetQuitLockString	
SetQuitLockStringWide	
StartProcessServerWide	Starts a process server.
StartServerWide	Starts a debugging server.

Requirements

IDebugClient5::AttachKernelWide method

The **AttachKernelWide** method connects the [debugger engine](#) to a kernel target.

Syntax

```
C++
HRESULT AttachKernelWide(
    [in]          ULONG   Flags,
    [in, optional] PCWSTR ConnectOptions
);
```

Parameters

Flags [in]

Specifies the flags that control how the debugger attaches to the kernel target. The possible values are:

Value	Description
DEBUG_ATTACH_KERNEL_CONNECTION	Attach to the kernel on the target computer.

DEBUG_ATTACH_EXDI_DRIVER Attach to a kernel by using an eXDI driver.

ConnectOptions [in, optional]

Specifies the connection settings for communicating with the computer running the kernel target. The interpretation of *ConnectOptions* depends on the value of *Flags*.

DEBUG_ATTACH_KERNEL_CONNECTION

ConnectOptions will be interpreted the same way as the options that follow the **-k** switch on the WinDbg and KD command lines. Environment variables affect *ConnectOptions* in the same way they affect the **-k** switch.

DEBUG_ATTACH_EXDI_DRIVER

eXDI drivers are not described in this documentation. If you have an eXDI interface to your hardware probe or hardware simulator, please contact Microsoft for debugging information.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

Note The engine doesn't completely attach to the kernel until the [WaitForEvent](#) method has been called. Only after the kernel has generated an event -- for example, the initial breakpoint -- does it become available in the debugger session.

For more information about connecting to live kernel-mode targets, see [Live Kernel-Mode Targets](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

IDebugClient5::ConnectProcessServerWide method

The **ConnectProcessServerWide** method connects to a [process server](#).

Syntax

C++

```
HRESULT ConnectProcessServerWide(
    [in]  PCWSTR  RemoteOptions,
    [out] PULONG64 Server
);
```

Parameters

RemoteOptions [in]

Specifies how the [debugger engine](#) will connect with the process server. These are the same options passed to the **-remote** option on the WinDbg and CDB command lines. For details on the syntax of this string, see [Activating a Smart Client](#).

Server [out]

Receives a handle for the process server. This handle is used when creating or attaching to processes by using the process server.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

For more information about process servers and remote debugging, see [Process Servers, Kernel Connection Servers, and Smart Clients](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugClient5::CreateProcess2 method

The `CreateProcess2` method executes the given command to create a new process.

Syntax

```
C++  
HRESULT CreateProcess2(  
    [in]          ULONG64 Server,  
    [in]          PSTR  CommandLine,  
    [in]          PVOID OptionsBuffer,  
    [in]          ULONG OptionsBufferSize,  
    [in, optional] PCSTR  InitialDirectory,  
    [in, optional] PCSTR  Environment  
) ;
```

Parameters

Server [in]

Specifies the process server that will be attached to the process. If *Server* is zero, the engine will create the local process without using a process server.

CommandLine [in]

Specifies the command line to execute to create the new process.

OptionsBuffer [in]

Specifies the process creation options. *OptionsBuffer* is a pointer to a [DEBUG_CREATE_PROCESS_OPTIONS](#) structure.

OptionsBufferSize [in]

Specifies the size of the buffer *OptionsBuffer*. This should be set to `sizeof(DEBUG_CREATE_PROCESS_OPTIONS)`.

InitialDirectory [in, optional]

Specifies the starting directory for the process. If *InitialDirectory* is `NULL`, the current directory for the process server is used.

Environment [in, optional]

Specifies an environment block for the new process. An environment block consists of a null-terminated block of null-terminated strings. Each string is of the form:

```
name=value
```

Note that the last two characters of the environment block are both **NULL**: one to terminate the string and one to terminate the block.

If *Environment* is set to **NULL**, the new process inherits the environment block of the process server. If the **DEBUG_CREATE_PROCESS_THROUGH_RTL** flag is set in *OptionsBuffer*, then *Environment* must be **NULL**.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

This method is available only for live user-mode debugging.

If *CreateFlags* contains either of the flags **DEBUG_PROCESS** or **DEBUG_ONLY_THIS_PROCESS**, the engine will also attach to the newly created process. This is similar to the behavior of [CreateProcessAndAttach2](#) with its argument *ProcessId* set to zero.

For more information about creating and attaching to live user-mode targets, see [Live User-Mode Targets](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugClient5::CreateProcess2Wide method

The **CreateProcess2Wide** method executes the specified command to create a new process.

Syntax

```
C++

HRESULT CreateProcess2Wide(
    [in]           ULONG64 Server,
    [in]           PWSTR   CommandLine,
    [in]           PVOID   OptionsBuffer,
    [in]           ULONG   OptionsBufferSize,
    [in, optional] PCWSTR  InitialDirectory,
    [in, optional] PCWSTR  Environment
);
```

Parameters

Server [in]

Specifies the process server that will be attached to the process. If *Server* is zero, the engine will create the local process without using a process server.

CommandLine [in]

Specifies the command line to execute to create the new process.

OptionsBuffer [in]

Specifies the process creation options. *OptionsBuffer* is a pointer to a [DEBUG_CREATE_PROCESS_OPTIONS](#) structure.

OptionsBufferSize [in]

Specifies the size of the buffer *OptionsBuffer*. This should be set to `sizeof(DEBUG_CREATE_PROCESS_OPTIONS)`.

InitialDirectory [in, optional]

Specifies the starting directory for the process. If *InitialDirectory* is `NULL`, the current directory for the process server is used.

Environment [in, optional]

Specifies an environment block for the new process. An environment block consists of a null-terminated block of null-terminated strings. Each string is of the form:

`name=value`

Note that the last two characters of the environment block are both `NULL`: one to terminate the string and one to terminate the block.

If *Environment* is set to `NULL`, the new process inherits the environment block of the process server. If the `DEBUG_CREATE_PROCESS_THROUGH_RTL` flag is set in *OptionsBuffer*, then *Environment* must be `NULL`.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
<code>S_OK</code>	The method was successful.

Remarks

This method is available only for live user-mode debugging.

If *CreateFlags* contains either of the flags `DEBUG_PROCESS` or `DEBUG_ONLY_THIS_PROCESS`, the engine will also attach to the newly created process. This is similar to the behavior of [CreateProcessAndAttach2](#) with its argument *ProcessId* set to zero.

For more information about creating and attaching to live user-mode targets, see [Live User-Mode Targets](#).

IDebugClient5::CreateProcessAndAttach2 method

The `CreateProcessAndAttach2` method creates a process from a specified command line, then attaches to that process or another user-mode process.

Syntax

C++

```
HRESULT CreateProcessAndAttach2(
    [in]           ULONG64 Server,
    [in, optional] PSTR   CommandLine,
    [in]           PVOID  OptionsBuffer,
```

```
[in]      ULONG    OptionsBufferSize,
[in, optional] PCSTR   InitialDirectory,
[in, optional] PCSTR   Environment,
[in]      ULONG    ProcessId,
[in]      ULONG    AttachFlags
);
```

Parameters

Server [in]

Specifies the process server to use to attach to the process. If *Server* is zero, the engine will connect to the local process without using a process server.

CommandLine [in, optional]

Specifies the command line to execute to create the new process. If *CommandLine* is **NULL**, no process is created and these methods will use *ProcessId* to attach to an existing process.

OptionsBuffer [in]

Specifies the process creation options. *OptionsBuffer* is a pointer to a [DEBUG_CREATE_PROCESS_OPTIONS](#) structure.

OptionsBufferSize [in]

Specifies the size of the buffer *OptionsBuffer*. This should be set to `sizeof(DEBUG_CREATE_PROCESS_OPTIONS)`.

InitialDirectory [in, optional]

Specifies the starting directory for the process. This parameter is used only if *CommandLine* is not **NULL**. If *InitialDirectory* is **NULL**, the current directory for the process server is used.

Environment [in, optional]

Specifies an environment block for the new process. An environment block consists of a null-terminated block of null-terminated strings. Each string is of the form:

```
name=value
```

Note that the last two characters of the environment block are both **NULL**: one to terminate the string and one to terminate the block.

If *Environment* is set to **NULL**, the new process inherits the environment block of the process server. If the `DEBUG_CREATE_PROCESS_THROUGH_RTL` flag is set in *OptionsBuffer*, then *Environment* must be **NULL**.

ProcessId [in]

Specifies the process ID of the target process to which the debugger will attach. If *ProcessID* is zero, the debugger will attach to the process it created from *CommandLine*.

AttachFlags [in]

Specifies the flags that control how the debugger attaches to the target process. For details on these flags, see [DEBUG_ATTACH_XXX](#).

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
E_INVALIDARG	This is returned if <i>CommandLine</i> is NULL and <i>ProcessId</i> is zero.

Remarks

This method is available only for live user-mode debugging.

If *CommandLine* is not **NULL** and *ProcessId* is not zero, then the engine will create the process in a suspended state. The engine will resume this newly created process after it successfully connects to the process specified in *ProcessId*.

Note The engine doesn't completely attach to the process until the [WaitForEvent](#) method has been called. Only after the process has generated an event -- for example, the create-process event -- does it become available in the debugger session.

For more information about creating and attaching to live user-mode targets, see [Live User-Mode Targets](#).

IDebugClient5::CreateProcessAndAttach2Wide method

The **CreateProcessAndAttach2Wide** method creates a process from a specified command line, then attach to that process or another user-mode process.

Syntax

```
C++  
HRESULT CreateProcessAndAttach2Wide(  
    [in]           ULONG64 Server,  
    [in, optional] PWSTR   CommandLine,  
    [in]           PVOID    OptionsBuffer,  
    [in]           ULONG    OptionsBufferSize,  
    [in, optional] PCWSTR   InitialDirectory,  
    [in, optional] PCWSTR   Environment,  
    [in]           ULONG    ProcessId,  
    [in]           ULONG    AttachFlags  
) ;
```

Parameters

Server [in]

Specifies the process server to use to attach to the process. If *Server* is zero, the engine will connect to the local process without using a process server.

CommandLine [in, optional]

Specifies the command line to execute to create the new process. If *CommandLine* is **NULL**, no process is created and these methods will use *ProcessId* to attach to an existing process.

OptionsBuffer [in]

Specifies the process creation options. *OptionsBuffer* is a pointer to a [DEBUG_CREATE_PROCESS_OPTIONS](#) structure.

OptionsBufferSize [in]

Specifies the size of the buffer *OptionsBuffer*. This should be set to **sizeof(DEBUG_CREATE_PROCESS_OPTIONS)**.

InitialDirectory [in, optional]

Specifies the starting directory for the process. This parameter is used only if *CommandLine* is not **NULL**. If *InitialDirectory* is **NULL**, the current directory for the process server is used.

Environment [in, optional]

Specifies an environment block for the new process. An environment block consists of a null-terminated block of null-terminated strings. Each string is of the form:

name=value

Note that the last two characters of the environment block are both **NULL**: one to terminate the string and one to terminate the block.

If *Environment* is set to **NULL**, the new process inherits the environment block of the process server. If the **DEBUG_CREATE_PROCESS_THROUGH_RTL** flag is set in *OptionsBuffer*, then *Environment* must be **NULL**.

ProcessId [in]

Specifies the process ID of the target process to which the debugger will attach. If *ProcessID* is zero, the debugger will attach to the process it created from *CommandLine*.

AttachFlags [in]

Specifies the flags that control how the debugger attaches to the target process. For details on these flags, see [DEBUG_ATTACH_XXX](#).

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
E_INVALIDARG	This is returned if <i>CommandLine</i> is NULL and <i>ProcessId</i> is zero.

Remarks

This method is available only for live user-mode debugging.

If *CommandLine* is not **NULL** and *ProcessId* is not zero, then the engine will create the process in a suspended state. The engine will resume this newly created process after it successfully connects to the process specified in *ProcessId*.

Note The engine doesn't completely attach to the process until the [WaitForEvent](#) method has been called. Only after the process has generated an event -- for example, the create-process event -- does it become available in the debugger session.

For more information about creating and attaching to live user-mode targets, see [Live User-Mode Targets](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugClient5::GetEventCallbacksWide method

The **GetEventCallbacksWide** method returns the event callbacks object registered with this client.

Syntax

```
C++  
HRESULT GetEventCallbacksWide(  
    [out] PDEBUG_EVENT_CALLBACKS_WIDE *Callbacks  
) ;
```

Parameters

Callbacks [out]

Receives an interface pointer to the event callbacks object registered with this client.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

Each client can have at most one [IDebugEventCallbacks](#) or [IDebugEventCallbacksWide](#) object registered with it for receiving [events](#).

If no event callbacks object is registered with the client, the value of *Callbacks* will be set to **NULL**.

The **IDebugEventCallbacksWide** interface extends the COM interface **IUnknown**. Before returning the **IDebugEventCallbacksWide** object specified by *Callbacks*, the engine calls its **IUnknown::AddRef** method. When this object is no longer needed, its **IUnknown::Release** method should be called.

For more information about callbacks, see [Callbacks](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugClient5::GetIdentityWide method

The **GetIdentityWide** method returns a string describing the computer and user this client represents.

Syntax

```
C++  
HRESULT GetIdentityWide(  
    [out, optional] PWSTR Buffer,  
    [in]          ULONG   BufferSize,  
    [out, optional] PULONG IdentitySize  
) ;
```

Parameters

Buffer [out, optional]

Specifies the buffer to receive the string. If *Buffer* is **NULL**, this information is not returned.

BufferSize [in]

Specifies the size of the buffer *Buffer*.

IdentitySize [out, optional]

Receives the size of the string. If *IdentitySize* is **NULL**, this information is not returned.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful
S_FALSE	The size of the string was greater than the size of the buffer, so it was truncated to fit into the buffer.

Remarks

The specific content of the string varies with the operating system. If the client is remotely connected, some network information may also be present.

For more information about client objects, see [Client Objects](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

IDebugClient5

OutputIdentity

IDebugClient5::GetKernelConnectionOptionsWide method

The **GetKernelConnectionOptionsWide** method returns the connection options for the current kernel target.

Syntax

C++

```
HRESULT GetKernelConnectionOptionsWide(
    [out, optional] PWSTR Buffer,
    [in]          ULONG BufferSize,
    [out, optional] PULONG OptionsSize
);
```

Parameters

Buffer [out, optional]

Specifies the buffer to receive the connection options.

BufferSize [in]

Specifies the size in characters of the buffer *Buffer*.

OptionsSize [out, optional]

Receives the size in characters of the connection options. If *OptionsSize* is **NULL**, this information is not returned.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
S_FALSE	The size of the string was greater than the size of the buffer, so it was truncated to fit into the buffer.
E_UNEXPECTED	The current target is not a standard live kernel target.

Remarks

This method is available only for live kernel targets that are not local and not connected through eXDI.

The connection options returned are the same options used to connect to the kernel.

For more information about connecting to live kernel-mode targets, see [Live Kernel-Mode Targets](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugClient5::GetNumberEventCallbacks method

The **GetNumberEventCallbacks** method returns the number of event callbacks that are interested in the given [events](#).

Syntax

```
C++  
HRESULT GetNumberEventCallbacks(  
    [in]  ULONG EventFlags,  
    [out] PULONG Count  
) ;
```

Parameters

EventFlags [in]

Specifies a set of events used to filter out some of the event callbacks; only event callbacks that have indicated an interest in one of the events in *EventFlags* will be counted. See [DEBUG_EVENT_XXX](#) for a list of the events.

Count [out]

Receives the number of event callbacks that are interested in at least one of the events in *EventFlags*.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

Each client can have at most one event callback registered with it. When a callback is registered with a client, its [IDebugEventCallbacks::GetInterestMask](#) method is called to allow the client to specify which events it is interested in.

For more information about callbacks, see [Callbacks](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugClient5::GetNumberInputCallbacks method

The **GetNumberInputCallbacks** method returns the number of [input callbacks](#) registered over all clients.

Syntax

```
C++  
HRESULT GetNumberInputCallbacks(  
    [out] PULONG Count  
) ;
```

Parameters

Count [out]

Receives the number of input callbacks that have been registered.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

Each client can have at most one input callback registered with it.

For more information about callbacks, see [Callbacks](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugClient5::GetNumberOutputCallbacks method

The **GetNumberOutputCallbacks** method returns the number of [output callbacks](#) registered over all clients.

Syntax

C++

```
HRESULT GetNumberOutputCallbacks (
    [out] PULONG Count
);
```

Parameters

Count [out]

Receives the number of output callbacks that have been registered.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

Each client can have at most one output callback registered with it.

For more information about callbacks, see [Callbacks](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugClient5::GetOutputCallbacksWide method

The **GetOutputCallbacksWide** method returns the [output callbacks](#) object registered with the client.

Syntax

```
C++
HRESULT GetOutputCallbacksWide(
    [out] PDEBUG_OUTPUT_CALLBACKS_WIDE *Callbacks
);
```

Parameters

Callbacks [out]

Receives an interface pointer to the [IDebugOutputCallbacks](#) object registered with the client.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

Each client can have at most one [IDebugOutputCallbacks](#) or [IDebugOutputCallbacksWide](#) object registered with it for output.

If no output callbacks object is registered with the client, the value of *Callbacks* will be set to **NULL**.

The [IDebugOutputCallbacksWide](#) interface extends the COM interface [IUnknown](#). Before returning the [IDebugOutputCallbacksWide](#) object specified by *Callbacks*, the engine calls its [IUnknown::AddRef](#) method. When this object is no longer needed, its [IUnknown::Release](#) method should be called.

For more information about callbacks, see [Callbacks](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugClient5::OutputIdentityWide method

The **OutputIdentityWide** method formats and outputs a string describing the computer and user this client represents.

Syntax

```
C++
```

```
HRESULT OutputIdentityWide(
    [in] ULONG OutputControl,
    [in] ULONG Flags,
    [in] PCWSTR Format
);
```

Parameters

OutputControl [in]

Specifies where to send the output. For possible values, see [DEBUG_OUTCTL_XXX](#).

Flags [in]

Set to zero.

Format [in]

Specifies a format string similar to the `printf` format string. However, this format string must only contain one formatting directive, `%s`, which will be replaced by a description of the computer and user this client represents.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

The specific content of the string varies with the operating system. If the client is remotely connected, some network information may also be present.

For more information about client objects, see [Client Objects](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

IDebugClient5::OutputServersWide method

The `OutputServersWide` method lists the servers running on a given computer.

Syntax

```
C++
HRESULT OutputServersWide(
    [in] ULONG OutputControl,
    [in] PCWSTR Machine,
    [in] ULONG Flags
);
```

Parameters

OutputControl [in]

Specifies the output control to use while outputting the servers. For possible values, see [DEBUG_OUTCTL_XXX](#).

Machine [in]

Specifies the name of the computer whose servers will be listed. *Machine* has the following form:

`\computername`

Flags [in]

Specifies a bit-set that determines which servers to output. The possible bit flags are:

Flag	Description
DEBUG_SERVERS_DEBUGGER	Output the debugging servers on the computer.
DEBUG_SERVERS_PROCESS	Output the process servers on the computer.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

For more information about remote debugging, see [Remote Debugging](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

IDebugClient5::SetEventCallbacksWide method

The **SetEventCallbacksWide** method registers an event callbacks object with this client.

Syntax

```
C++
HRESULT SetEventCallbacksWide(
    [in] PDEBUG_EVENT_CALLBACKS_WIDE Callbacks
);
```

Parameters

Callbacks [in]

Specifies the interface pointer to the event callbacks object to register with this client.

Return value

Depending on the implementation of the method [IDebugEventCallbacks::GetInterestMask](#) in the object specified by *Callbacks*, other values may be returned, as described in the Remarks section.

Return code	Description
S_OK	The method was successful.

Remarks

If the value of *Callbacks* is not **NULL**, the method [IDebugEventCallbacks::GetInterestMask](#) is called. If the return value is not S_OK, **SetEventCallbacks** and **SetEventCallbacksWide** have no effect and they return this value.

Each client can have at most one [IDebugEventCallbacks](#) or [IDebugEventCallbacksWide](#) object registered with it for receiving [events](#).

The **IDebugEventCallbacksWide** interface extends the COM interface **IUnknown**. When **SetEventCallbacks** and **SetEventCallbacksWide** are successful, they call the **IUnknown::AddRef** method of the object specified by *Callbacks*. The **IUnknown::Release** method of this object will be called the next time **SetEventCallbacks** or **SetEventCallbacksWide** is called on this client, or when this client is deleted.

For more information about callbacks, see [Callbacks](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

IDebugClient5::SetKernelConnectionOptionsWide method

The **SetKernelConnectionOptionsWide** method updates some of the connection options for a live kernel target.

Syntax

C++

```
HRESULT SetKernelConnectionOptionsWide(
    [in] PCWSTR Options
);
```

Parameters

Options [in]

Specifies the connection options to update. The possible values are:

Value	Description
"resync"	Re-synchronize the connection between the debugger engine and the kernel. For more information, see Synchronizing with the Target Computer .
"cycle_speed"	For kernel connections through a COM port, cycle through the supported baud rates; for other connections, do nothing. For more information, see CTRL+A (Toggle Baud Rate) .

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
E_UNEXPECTED	The current target is not a live (non-local) kernel target.

Remarks

This method is available only for live kernel targets that are not local and not connected through eXDI. This method is reentrant.

For more information about connecting to live kernel-mode targets, see [Live Kernel-Mode Targets](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugClient5](#)
[AttachKernel](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugClient5::SetOutputCallbacksWide method

The **SetOutputCallbacksWide** method registers an [output callbacks](#) object with this client.

Syntax

C++

```
HRESULT SetOutputCallbacksWide(
    [in] PDEBUG_OUTPUT_CALLBACKS_WIDE Callbacks
);
```

Parameters

Callbacks [in]

Specifies the interface pointer to the output callbacks object to register with this client.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

Each client can have at most one [IDebugOutputCallbacks](#) or [IDebugOutputCallbacksWide](#) object registered with it for output.

The [IDebugOutputCallbacksWide](#) interface extends the COM interface [IUnknown](#). [SetOutputCallbacks](#) and [SetOutputCallbacksWide](#) call the [IUnknown::AddRef](#) method in the object specified by *Callbacks*. The [IUnknown::Release](#) method of this interface will be called the next time [SetOutputCallbacks](#) or [SetOutputCallbacksWide](#) is called on this client, or when this client is deleted.

For more information about callbacks, see [Callbacks](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugClient5](#)
[IDebugOutputCallbacks](#)
[GetOutputCallbacks](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugClient5::StartProcessServerWide method

The **StartProcessServerWide** method starts a process server.

Syntax

C++

```
HRESULT StartProcessServerWide(
    [in]          ULONG Flags,
    [in]          PCWSTR Options,
    [in, optional] PVOID Reserved
);
```

Parameters

Flags [in]

Specifies the class of the targets that will be available through the process server. This must be set to DEBUG_CLASS_USER_WINDOWS.

Options [in]

Specifies the connections options for this process server. These are the same options given to the **-t** option of the DbgSrv command line. For details on the syntax of this string, see [Activating a Process Server](#).

Reserved [in, optional]

Set to NULL.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

The process server that is started will be accessible by remote clients through the transport specified in the *Options* parameter.

To stop the process server from the smart client, use the [EndProcessServer](#) method. To shut down the process server from the computer that it is running on, use Task Manager to end the process. If the instance of the debugger engine that used [StartProcessServer](#) is still running, it can use [Execute](#) to issue the debugger command [.endsrv](#), which will end the process server (this is an exception to the usual behavior of [.endsrv](#), which generally does not affect process servers).

For more information about process servers and remote debugging, see [Process Servers, Kernel Connection Servers, and Smart Clients](#).

Requirements

Target platform

IDebugClient5::StartServerWide method

The [StartServerWide](#) method starts a debugging server.

Syntax

```
C++
HRESULT StartServerWide(
    [in] PCSTR Options
);
```

Parameters

Options [in]

Specifies the connections options for this server. These are the same options given to the **.server** debugger command or the WinDbg and CDB **-server** command-line option. For details on the syntax of this string, see [Activating a Debugging Server](#).

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

The server that is started will be accessible by other [debuggers](#) through the transport specified in the *Options* parameter.

For more information about debugging servers, see Debugging Server and Debugging Client.

Requirements

Target platform

IDebugControl interface

Members

The **IDebugControl** interface inherits from the **IUnknown** interface. **IDebugControl** also has these types of members:

- [Methods](#)

Methods

The **IDebugControl** interface has these methods.

Method	Description
AddBreakpoint	Creates a new breakpoint for the current target.
AddEngineOptions	Turns on some of the debugger engine's options.
AddExtension	Loads an extension library into the debugger engine.
Assemble	Assembles a single processor instruction. The assembled instruction is placed in the target's memory.
CallExtension	Calls a debugger extension.
CloseLogFile	Closes the currently-open log file.
CoerceValue	Converts a value of one type into a value of another type.
CoerceValues	Converts an array of values into an array of values of different types.
ControlledOutput	Formats a string and sends the result to output callbacks that were registered with some of the engine's clients.
ControlledOutputVaList	Formats a string and sends the result to output callbacks that were registered with some of the engine's clients.
Disassemble	Disassembles a processor instruction in the target's memory.
Evaluate	Evaluates an expression, returning the result.
Execute	Executes the specified debugger commands.
ExecuteCommandFile	Opens the specified file and executes the debugger commands that are contained within.
GetActualProcessorType	Returns the processor type of the physical processor of the computer that is running the target.
GetBreakpointById	Returns the breakpoint with the specified breakpoint ID.
GetBreakpointByIndex	Returns the breakpoint located at the specified index.
GetBreakpointParameters	Returns the parameters of one or more breakpoints.
GetCodeLevel	Returns the current code level and is mainly used when stepping through code.
GetDebuggeeType	Describes the nature of the current target.
GetDisassembleEffectiveOffset	Returns the address of the last instruction disassembled using Disassemble.
GetEffectiveProcessorType	Returns the effective processor type of the processor of the computer that is running the target.
GetEngineOptions	Returns the engine's options.
GetEventFilterCommand	Returns the debugger command that the engine will execute when a specified event occurs.
GetEventFilterText	Returns a short description of an event for a specific filter.
GetExceptionFilterParameters	Returns the parameters for exception filters specified by exception codes or by index.
GetExceptionFilterSecondCommand	Returns the command that will be executed by the debugger engine upon the second chance of a specified exception.
GetExecutingProcessorType	Returns the executing processor type for the processor for which the last event occurred.
GetExecutionStatus	Returns information about the execution status of the debugger engine.
GetExtensionByPath	Returns the handle for an already loaded extension library.

GetExtensionFunction	Returns a pointer to an extension function from an extension library.
GetInterrupt	Checks whether a user interrupt was issued.
GetInterruptTimeout	Returns the number of seconds that the engine will wait when requesting a break into the debugger.
GetLastEventInformation	Returns information about the last event that occurred in a target.
GetLogFile	Returns the name of the currently open log file.
GetLogMask	Returns the output mask for the currently open log file. HRESULT
GetNearInstruction	Returns the location of a processor instruction relative to a given location.
GetNotifyEventHandle	Receives the handle of the event that will be signaled after the next exception in a target.
GetNumberBreakpoints	Returns the number of breakpoints for the current process.
GetNumberEventFilters	Returns the number of event filters currently used by the engine.
GetNumberPossibleExecutingProcessorTypes	Returns the number of processor types that are supported by the computer running the current target.
GetNumberProcessors	Returns the number of processors on the computer running the current target.
GetNumberSupportedProcessorTypes	Returns the number of processor types supported by the engine.
GetPageSize	Returns the page size for the effective processor mode.
GetPossibleExecutingProcessorTypes	Returns the processor types that are supported by the computer running the current target.
GetProcessorTypeNames	Returns the full name and abbreviated name of the specified processor type.
GetPromptText	Returns the standard prompt text that will be prepended to the formatted output specified in the OutputPrompt and OutputPromptVaList methods.
GetRadix	Returns the default radix (number base) used by the debugger engine when it evaluates and displays MASM expressions, and when it displays symbol information.
GetReturnOffset	Returns the return address for the current function.
GetSpecificFilterArgument	Returns the value of filter argument for the specific filters that have an argument.
GetSpecificFilterParameters	Returns the parameters for specific event filters.
GetStackTrace	Returns the frames at the top of the specified call stack.
GetSupportedProcessorTypes	Returns the processor types supported by the debugger engine.
GetSystemErrorControl	Returns the control values for handling system errors.
GetSystemVersion	Returns information that identifies the operating system on the computer that is running the current target.
GetTextMacro	Returns the value of a fixed-name alias.
GetWindbgExtensionApis32	returns a structure that facilitates using the WdbgExts API.
GetWindbgExtensionApis64	Requests an input string from the debugger engine.
Input	Determines if the effective processor uses 64-bit pointers.
IsPointer64Bit	Opens a log file that will receive output from the client objects.
OpenLogFile	Formats a string and sends the result to output callbacks that have been registered with the engine's clients.
Output	Prints the current state of the current target to the debugger console.
OutputCurrentState	Disassembles a processor instruction and sends the disassembly to the output callbacks.
OutputDisassembly	Disassembles several processor instructions and sends the resulting assembly instructions to the output callbacks.
OutputDisassemblyLines	Formats and sends a user prompt to the output callback objects.
OutputPrompt	Formats and sends a user prompt to the output callback objects.
OutputPromptVaList	Outputs either the supplied stack frame or the current stack frames.
OutputStackTrace	Formats a string and sends the result to the output callbacks that are registered with the engine's clients.
OutputVaList	Prints version information about the debugger engine to the debugger console.
OutputVersionInformation	Reads the kernel bug check code and related parameters.
ReadBugCheckData	Removes a breakpoint.
RemoveBreakpoint	Turns off some of the engine's options.
RemoveEngineOptions	Unloads an extension library.
RemoveExtension	This method is used by IDebugInputCallbacks objects to send an input string to the engine following a request for input.
ReturnInput	Sets the current code level and is mainly used when stepping through code.
SetCodeLevel	Sets the effective processor type of the processor of the computer that is running the target.
SetEffectiveProcessorType	Changes the engine's options.
SetEngineOptions	Sets a debugger command for the engine to execute when a specified event occurs.
SetEventFilterCommand	Changes the break status and handling status for some exception filters.
SetExceptionFilterParameters	Sets the command that will be executed by the debugger engine on the second chance of a specified exception.
SetExceptionFilterSecondCommand	Requests that the debugger engine enter an executable state. Actual execution will not occur until the next time WaitForEvent is called.
SetExecutionStatus	Registers a user interrupt or breaks into the debugger.
SetInterrupt	Sets the number of seconds that the debugger engine should wait when requesting a break into the debugger.
SetInterruptTimeout	Sets the output mask for the currently open log file.
SetLogMask	Sets the event that will be signaled after the next exception in a target.
SetNotifyEventHandle	Sets the default radix (number base) used by the debugger engine when it evaluates and displays MASM expressions, and when it displays symbol information.
SetRadix	Sets the value of filter argument for the specific filters that can have an argument.
SetSpecificFilterArgument	Changes the break status and handling status for some specific event filters.
SetSpecificFilterParameters	Sets the control values for handling system errors.
SetSystemErrorControl	Sets the value of a fixed-name alias.
SetTextMacro	Waits for an event that breaks into the debugger engine application.
WaitForEvent

IDebugControl::AddBreakpoint method

The **AddBreakpoint** method creates a new breakpoint for the current target.

Syntax

```
C++  
HRESULT AddBreakpoint(  
    [in]  ULONG           Type,  
    [in]  ULONG           DesiredId,  
    [out] IDebugBreakpoint **Bp  
) ;
```

Parameters

Type [in]

Specifies the breakpoint type of the new breakpoint. This can be either of the following values:

Value	Description
DEBUG_BREAKPOINT_CODE	software breakpoint
DEBUG_BREAKPOINT_DATA	processor breakpoint

DesiredId [in]

Specifies the desired ID of the new breakpoint. If it is DEBUG_ANY_ID, the engine will pick an unused ID.

Bp [out]

Receives an interface pointer to the new breakpoint.

Return value

Return code	Description
S_OK	The method was successful.
E_INVALIDARG	The breakpoint couldn't be created with the desired ID or the value of <i>Type</i> was not recognized.

This method may also return other error values. See [Return Values](#) for more details.

Remarks

If *DesiredId* is not DEBUG_ANY_ID and another breakpoint already uses the ID *DesiredId*, these methods will fail.

Breakpoints are created empty and disabled. See [Using Breakpoints](#) for details on configuring and enabling the breakpoint.

The client is saved as the adder of the new breakpoint. See [GetAdder](#).

Note Even though [IDebugBreakpoint](#) extends the COM interface **IUnknown**, the lifetime of the breakpoint is not controlled using the **IUnknown** interface. Instead, the breakpoint is deleted after [RemoveBreakpoint](#) is called.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugControl](#)

IDebugControl::AddEngineOptions method

The **AddEngineOptions** method turns on some of the [debugger engine](#)'s options.

Syntax

```
C++
HRESULT AddEngineOptions(
    [in] ULONG Options
);
```

Parameters

Options [in]

Specifies engine options to turn on. *Options* is a bit-set that will be combined with the existing engine options using the bitwise-OR operator. For a description of the engine options, see [DEBUG_ENGOPT XXX](#).

Return value

Return code	Description
S_OK	The method was successful.

This method may also return error values. See [Return Values](#) for more details.

Remarks

After the engine options have been changed, the engine sends out notification to each client's [event callback object](#) by passing the DEBUG_CES_ENGINE_OPTIONS flag to the [IDebugEventCallbacks::ChangeEngineState](#) method.

Requirements

Target platform
Header Dbgeng.h (include Dbgeng.h)

IDebugControl::AddExtension method

The **AddExtension** method loads an extension library into the [debugger engine](#).

Syntax

```
C++  
HRESULT AddExtension(  
    [in]  PCSTR      Path,  
    [in]  ULONG      Flags,  
    [out] PULONG64   Handle  
) ;
```

Parameters

Path [in]

Specifies the fully qualified path and file name of the extension library to load.

Flags [in]

Set to zero.

Handle [out]

Receives the handle of the loaded extension library.

Return value

Return code	Description
S_OK	The method was successful.

This method can also return error values. See [Return Values](#) for more details.

Remarks

If the extension library has already been loaded, the handle to already loaded library is returned. The extension library is not loaded again.

The extension library is loaded into the host engine and *Path* contains a path and file name for this instance of the debugger engine.

For more information on using extension libraries, see [Calling Extensions and Extension Functions](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

IDebugControl::Assemble method

The **Assemble** method assembles a single processor instruction. The assembled instruction is placed in the target's memory.

Syntax

```
C++  
HRESULT Assemble(  
    [in]  ULONG64  Offset,  
    [in]  PCSTR     Instr,  
    [out] PULONG64  EndOffset  
) ;
```

Parameters

Offset [in]

Specifies the location in the target's memory to place the assembled instruction.

Instr [in]

Specifies the instruction to assemble. The instruction is assembled according to the target's effective processor type (returned by [SetEffectiveProcessorType](#)).

EndOffset [out]

Receives the location in the target's memory immediately following the assembled instruction. *EndOffset* can be used when assembling multiple instructions.

Return value

Return code	Description
S_OK	The method was successful.

This method can also return error values. See [Return Values](#) for more details.

Remarks

The assembly language depends on the effective processor type of the target machine. For information about the assembly language, see the processor documentation.

Note The **Assemble** and **AssembleWide** methods are not supported on some architectures, and on some other architectures not all instructions are supported.

The assembly language options--returned by [GetAssemblyOptions](#)--affect the operation of this method.

For an overview of using assembly in debugger applications, see [Debugging in Assembly Mode](#). For more information about using assembly with the [debugger engine API](#), see [Assembling and Disassembling Instructions](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

IDebugControl::CallExtension method

The **CallExtension** method calls a debugger extension.

Syntax

```
C++
HRESULT CallExtension(
    [in]          ULONG64 Handle,
    [in]          PCSTR   Function,
    [in, optional] PCSTR   Arguments
);
```

Parameters

Handle [in]

Specifies the handle of the extension library that contains the extension to call. If *Handle* is zero, the engine will walk the extension library chain searching for the extension.

Function [in]

Specifies the name of the extension to call.

Arguments [in, optional]

Specifies the arguments to pass to the extension. *Arguments* is a string that will be parsed by the extension, just like the extension will parse arguments passed to it when

called as an extension command.

Return value

Return code	Description
S_OK	The method was successful.

This method can also return error values. See [Return Values](#) for more details.

Remarks

If *Handle* is zero, the engine searches each extension library until it finds one that contains the extension; the extension will then be called. If the extension returns DEBUG_EXTENSION_CONTINUE_SEARCH, the search will continue.

For more information on using extension libraries, see [Calling Extensions and Extension Functions](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugControl](#)

IDebugControl::CloseLogFile method

The **CloseLogFile** method closes the currently-open log file.

Syntax

```
C++
HRESULT CloseLogFile();
```

Parameters

This method has no parameters.

Return value

Return code	Description
S_OK	The method was successful.

This method can also return error values. See [Return Values](#) for more details.

Remarks

If no log file is open, this method has no effect.

For more about log files, see [Using Input and Output](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

IDebugControl::CoerceValue method

The **CoerceValue** method converts a value of one type into a value of another type.

Syntax

```
C++  
HRESULT CoerceValue(  
    [in] PDEBUG_VALUE In,  
    [in] ULONG OutType,  
    [out] PDEBUG_VALUE Out  
) ;
```

Parameters

In [in]

Specifies the value to be converted

OutType [in]

Specifies the desired type for the converted value. See [DEBUG VALUE](#) for possible values.

Out [out]

Receives the converted value. The type of this value will be the type specified by *OutType*.

Return value

Return code	Description
S_OK	The method was successful.

This method may also return error values. See [Return Values](#) for more details.

Remarks

This method converts a value of one type into a value of another type. If the specified *OutType* is not capable of containing the information supplied by the *In* variable, data will be lost.

Requirements

Target platform
Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugControl](#)
[IDebugControl2](#)
[IDebugControl3](#)
[DEBUG VALUE](#)

[Send comments about this topic to Microsoft](#)

IDebugControl::CoerceValues method

The **CoerceValues** method converts an array of values into an array of values of different types.

Syntax

```
C++
HRESULT CoerceValues(
    [in] ULONG          Count,
    [in] PDEBUG_VALUE  In,
    [in] PULONG         OutType,
    [out] PDEBUG_VALUE Out
);
```

Parameters

Count [in]

Specifies the number of values to convert.

In [in]

Specifies the array of values to convert. The number of elements that this array holds is *Count*.

OutType [in]

Specifies the array of desired types for the converted values. For possible values, see [DEBUG_VALUE](#). The number of elements that this array holds is *Count*.

Out [out]

Specifies the array to be populated by the converted values. The types of these values are specified by *OutType*. The number of elements that this array holds is *Count*.

Return value

Return code	Description
S_OK	The method was successful.

This method may also return error values. See [Return Values](#) for more details.

Remarks

This method converts an array of values of one type into values of another type. Some of these conversions can result in loss of precision.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

IDebugControl::ControlledOutput method

The **ControlledOutput** method formats a string and sends the result to [output callbacks](#) that were registered with some of the engine's clients.

Syntax

```
C++
HRESULT ControlledOutput(
    [in] ULONG OutputControl,
    [in] ULONG Mask,
    [in] PCSTR Format,
    ...
);
```

);

Parameters

OutputControl [in]

Specifies an output control that determines which of the clients' output callbacks will receive the output. For possible values, see [DEBUG_OUTCTL_XXX](#). For more information about output, see [Input and Output](#).

Mask [in]

Specifies the output-type bit field. See [DEBUG_OUTPUT_XXX](#) for possible values.

Format [in]

Specifies the format string, as in **printf**. Typically, conversion characters work exactly as they do in C. For the floating-point conversion characters, the 64-bit argument is interpreted as a 32-bit floating-point number unless the **I** modifier is used.

The **%p** conversion character is supported, but it represents a pointer in a target's address space. It might not have any modifiers and it uses the debugger's internal address formatting. The following additional conversion characters are supported.

Character	Argument type	Argument	Text printed
%p	ULONG64	Pointer in an address space.	The value of the pointer.
%N	DWORD_PTR (32 or 64 bits, depending on the host's architecture)	Pointer in the host's virtual address space.	The value of the pointer. (This is equivalent to the standard C %p character.)
%I	ULONG64	Any 64-bit value.	The specified value. If this is greater than 0xFFFFFFFF, it is printed as a 64-bit value; otherwise, it is printed as a 32-bit value.
%ma	ULONG64	Address of a NULL-terminated ASCII string in the process's virtual address space.	The specified string.
%mu	ULONG64	Address of a NULL-terminated Unicode string in the process's virtual address space.	The specified string.
%msa	ULONG64	Address of an ANSI_STRING structure in the process's virtual address space.	The specified string.
%msu	ULONG64	Address of a UNICODE_STRING structure in the process's virtual address space.	The specified string.
%y	ULONG64	Address in the process's virtual address space of an item with symbol information.	String that contains the name of the specified symbol (and displacement, if any).
%ly	ULONG64	Address in the process's virtual address space of an item with symbol information.	String that contains the name of the specified symbol (and displacement, if any), as well as any available source line information.

The **%Y** format specifier can be used to support the Debugger Markup Language (DML). For more information, see [Customizing Debugger Output Using DML](#).

The following table summarizes the use of the **%Y** format specifier.

Character	Argument type	Argument	Text printed
%Y{t}	String	Text	Quoted string. Will convert text to DML if the output format (first arg) is DML.
%Y{T}	String	Text	Quoted string. Will always convert text to DML regardless of the output format.
%Y{s}	String	Text	Unquoted string. Will convert text to DML if the output format (first arg) is DML.
%Y{S}	String	Text	Unquoted string. Will always convert text to DML regardless of the output format.
%Y{as}	ULONG64	Debugger formatted pointer	Adds either an empty string or 9 characters of spacing for padding the high 32-bit portion of debugger formatted pointer fields. The extra space outputs 9 spaces which includes the upper 8 zeros plus the ' character.
%Y{ps}	ULONG64	Debugger formatted pointer	Adds either an empty string or 8 characters of spacing for padding the high 32-bit portion of debugger formatted pointer fields.
%Y{l}	ULONG64	Debugger formatted pointer	Address as source line information.

This code snippet illustrates the use of the **%Y** format specifier.

```

HRESULT CALLBACK testout(_In_ PDEBUG_CLIENT pClient, _In_ PCWSTR /*pwszArgs*/)
{
    HRESULT hr = S_OK;

    ComPtr<IDebugControl4> spControl;
    IfFailedReturn(pClient->QueryInterface(IID_PPV_ARGS(&spControl)));

    spControl->ControlledOutputWide(DEBUG_OUTCTL_DML, DEBUG_OUTPUT_NORMAL, L"DML/NORMAL Y{t}: %Y(t)\n", L"Hello <World>");
    spControl->ControlledOutputWide(DEBUG_OUTCTL_DML, DEBUG_OUTPUT_NORMAL, L"DML/NORMAL Y{T}: %Y(T)\n", L"Hello <World>");
    spControl->ControlledOutputWide(DEBUG_OUTCTL_DML, DEBUG_OUTPUT_NORMAL, L"DML/NORMAL Y{s}: %Y(s)\n", L"Hello <World>");
    spControl->ControlledOutputWide(DEBUG_OUTCTL_DML, DEBUG_OUTPUT_NORMAL, L"DML/NORMAL Y{S}: %Y(S)\n", L"Hello <World>");

    spControl->ControlledOutputWide(0, DEBUG_OUTPUT_NORMAL, L"TEXT/NORMAL Y{t}: %Y(t)\n", L"Hello <World>");
    spControl->ControlledOutputWide(0, DEBUG_OUTPUT_NORMAL, L"TEXT/NORMAL Y{T}: %Y(T)\n", L"Hello <World>");
    spControl->ControlledOutputWide(0, DEBUG_OUTPUT_NORMAL, L"TEXT/NORMAL Y{s}: %Y(s)\n", L"Hello <World>");
    spControl->ControlledOutputWide(0, DEBUG_OUTPUT_NORMAL, L"TEXT/NORMAL Y{S}: %Y(S)\n", L"Hello <World>");

    spControl->ControlledOutputWide(DEBUG_OUTCTL_DML, DEBUG_OUTPUT_NORMAL, L"DML/NORMAL Y(a): %Y(a)\n", (ULONG64)0x00007ffa7da163c0);

```

```

    spControl->ControlledOutputWide(DEBUG_OUTCTL_DML, DEBUG_OUTPUT_NORMAL, L"DML/NORMAL Y{as} 64bit : '%Y{as}'\n", (ULONG64)0x00007ff
    spControl->ControlledOutputWide(DEBUG_OUTCTL_DML, DEBUG_OUTPUT_NORMAL, L"DML/NORMAL Y{as} 32value : '%Y{as}'\n", (ULONG64)0x1);

    spControl->ControlledOutputWide(DEBUG_OUTCTL_DML, DEBUG_OUTPUT_NORMAL, L"DML/NORMAL Y{ps} 64bit : '%Y{ps}'\n", (ULONG64)0x00007ff
    spControl->ControlledOutputWide(DEBUG_OUTCTL_DML, DEBUG_OUTPUT_NORMAL, L"DML/NORMAL Y{ps} 32value : '%Y{ps}'\n", (ULONG64)0x1);

    spControl->ControlledOutputWide(DEBUG_OUTCTL_DML, DEBUG_OUTPUT_NORMAL, L"DML/NORMAL Y{l}: %Y{l}\n", (ULONG64)0x00007ffa7da163c0);

    return hr;
}

}

```

This sample code would generate the following output.

```

0:004> !testout
DML/NORMAL Y{t}: "Hello <World>"
DML/NORMAL Y{T}: "Hello <World>""
DML/NORMAL Y{s}: Hello <World>
DML/NORMAL Y{S}: Hello <World>
TEXT/NORMAL Y{t}: "Hello <World>"
TEXT/NORMAL Y{T}: &quot;Hello &lt;World&gt;&quot;
TEXT/NORMAL Y{s}: Hello <World>
TEXT/NORMAL Y{S}: Hello &lt;World&gt;
DML/NORMAL Y{a}: 00007ffa7da163c0
DML/NORMAL Y{as} 64bit :
DML/NORMAL Y{as} 32value :
DML/NORMAL Y{ps} 64bit :
DML/NORMAL Y{ps} 32value :
DML/NORMAL Y{l}: [d:\th\minkernel\kernelbase\debug.c @ 443]

...

```

Specifies additional parameters that represent values to be inserted into the output during formatting.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

When generating very large output strings, it is possible to reach the limits of the debugger engine or of the operating system. For example, some versions of the debugger engine have a 16K character limit for a single output. If you find that very large output is getting truncated, you might need to split your output into multiple requests.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugControl::ControlledOutputVaList method

The **ControlledOutputVaList** method formats a string and sends the result to [output callbacks](#) that were registered with some of the engine's clients.

Syntax

C++

```

HRESULT ControlledOutputVaList(
    [in] ULONG   OutputControl,
    [in] ULONG   Mask,
    [in] PCSTR   Format,
    [in] va_list Args
)

```

);

Parameters

OutputControl [in]

Specifies an output control that determines which client's output callbacks will receive the output. For possible values, see [DEBUG_OUTCTL_XXX](#). For more information about output, see [Input and Output](#).

Mask [in]

Specifies the output-type bit field. See [DEBUG_OUTPUT_XXX](#) for possible values.

Format [in]

Specifies the format string, as in **printf**. Typically, conversion characters work exactly as they do in C. For the floating-point conversion characters, the 64-bit argument is interpreted as a 32-bit floating-point number unless the **I** modifier is used.

The **%p** conversion character is supported, but it represents a pointer in a target's address space. It might not have any modifiers, and it uses the debugger's internal address formatting. The following additional conversion characters are supported.

Character	Argument type	Argument	Text printed
%p	ULONG64	Pointer in an address space.	The value of the pointer.
%N	DWORD_PTR (32 or 64 bits, depending on the host's architecture)	Pointer in the host's virtual address space.	The value of the pointer. (This is equivalent to the standard C %p character.)
%I	ULONG64	Any 64-bit value.	The specified value. If this is greater than 0xFFFFFFFF, it is printed as a 64-bit value; otherwise, it is printed as a 32-bit value.
%ma	ULONG64	Address of a NULL-terminated ASCII string in the process's virtual address space.	The specified string.
%mu	ULONG64	Address of a NULL-terminated Unicode string in the process's virtual address space.	The specified string.
%msa	ULONG64	Address of an ANSI_STRING structure in the process's virtual address space.	The specified string.
%msu	ULONG64	Address of a UNICODE_STRING structure in the process's virtual address space.	The specified string.
%y	ULONG64	Address in the process's virtual address space of an item with symbol information.	String that contains the name of the specified symbol (and displacement, if any).
%ly	ULONG64	Address in the process's virtual address space of an item with symbol information.	String that contains the name of the specified symbol (and displacement, if any), as well as any available source line information.

The **%Y** format specifier can be used to support the Debugger Markup Language (DML). For more information, see [Customizing Debugger Output Using DML](#).

The following table summarizes the use of the **%Y** format specifier.

Character	Argument type	Argument	Text printed
%Y{t}	String	Text	Quoted string. Will convert text to DML if the output format (first arg) is DML.
%Y{T}	String	Text	Quoted string. Will always convert text to DML regardless of the output format.
%Y{s}	String	Text	Unquoted string. Will convert text to DML if the output format (first arg) is DML.
%Y{S}	String	Text	Unquoted string. Will always convert text to DML regardless of the output format.
%Y{as}	ULONG64	Debugger formatted pointer	Adds either an empty string or 9 characters of spacing for padding the high 32-bit portion of debugger formatted pointer fields. The extra space outputs 9 spaces which includes the upper 8 zeros plus the ' character.
%Y{ps}	ULONG64	Debugger formatted pointer	Adds either an empty string or 8 characters of spacing for padding the high 32-bit portion of debugger formatted pointer fields.
%Y{l}	ULONG64	Debugger formatted pointer	Address as source line information.

This code snippet illustrates the use of the **%Y** format specifier.

```

HRESULT CALLBACK testout(_In_ PDEBUG_CLIENT pClient, _In_ PCWSTR /*pwszArgs*/)
{
    HRESULT hr = S_OK;

    ComPtr<IDebugControl4> spControl;
    IfFailedReturn(pClient->QueryInterface(IID_PPV_ARGS(&spControl)));

    spControl->ControlledOutputWide(DEBUG_OUTCTL_DML, DEBUG_OUTPUT_NORMAL, L"DML/NORMAL Y{t}: %Y(t)\n", L"Hello <World>");
    spControl->ControlledOutputWide(DEBUG_OUTCTL_DML, DEBUG_OUTPUT_NORMAL, L"DML/NORMAL Y{T}: %Y(T)\n", L"Hello <World>");
    spControl->ControlledOutputWide(DEBUG_OUTCTL_DML, DEBUG_OUTPUT_NORMAL, L"DML/NORMAL Y{s}: %Y(s)\n", L"Hello <World>");
    spControl->ControlledOutputWide(DEBUG_OUTCTL_DML, DEBUG_OUTPUT_NORMAL, L"DML/NORMAL Y{S}: %Y(S)\n", L"Hello <World>");

    spControl->ControlledOutputWide(0, DEBUG_OUTPUT_NORMAL, L"TEXT/NORMAL Y{t}: %Y(t)\n", L"Hello <World>");
    spControl->ControlledOutputWide(0, DEBUG_OUTPUT_NORMAL, L"TEXT/NORMAL Y{T}: %Y(T)\n", L"Hello <World>");
    spControl->ControlledOutputWide(0, DEBUG_OUTPUT_NORMAL, L"TEXT/NORMAL Y{s}: %Y(s)\n", L"Hello <World>");
    spControl->ControlledOutputWide(0, DEBUG_OUTPUT_NORMAL, L"TEXT/NORMAL Y{S}: %Y(S)\n", L"Hello <World>");

    spControl->ControlledOutputWide(DEBUG_OUTCTL_DML, DEBUG_OUTPUT_NORMAL, L"DML/NORMAL Y(a): %Y(a)\n", (ULONG64)0x00007ffa7da163c0);

```

```

    spControl->ControlledOutputWide(DEBUG_OUTCTL_DML, DEBUG_OUTPUT_NORMAL, L"DML/NORMAL Y{as} 64bit : '%Y{as}'\n", (ULONG64)0x00007ff
    spControl->ControlledOutputWide(DEBUG_OUTCTL_DML, DEBUG_OUTPUT_NORMAL, L"DML/NORMAL Y{as} 32value : '%Y{as}'\n", (ULONG64)0x1);

    spControl->ControlledOutputWide(DEBUG_OUTCTL_DML, DEBUG_OUTPUT_NORMAL, L"DML/NORMAL Y{ps} 64bit : '%Y{ps}'\n", (ULONG64)0x00007ff
    spControl->ControlledOutputWide(DEBUG_OUTCTL_DML, DEBUG_OUTPUT_NORMAL, L"DML/NORMAL Y{ps} 32value : '%Y{ps}'\n", (ULONG64)0x1);

    spControl->ControlledOutputWide(DEBUG_OUTCTL_DML, DEBUG_OUTPUT_NORMAL, L"DML/NORMAL Y{l}: %Y{l}\n", (ULONG64)0x00007ffa7da163c0);

    return hr;
}

}

```

This sample code would generate the following output.

```

0:004> !testout
DML/NORMAL Y{t}: "Hello <World>"  

DML/NORMAL Y{T}: "Hello <World>"  

DML/NORMAL Y{s}: Hello <World>  

DML/NORMAL Y{S}: Hello <World>  

TEXT/NORMAL Y{t}: "Hello <World>"  

TEXT/NORMAL Y{T}: &quot;Hello &lt;World&gt;&quot;  

TEXT/NORMAL Y{s}: Hello <World>  

TEXT/NORMAL Y{S}: Hello &lt;World&gt;  

DML/NORMAL Y{a}: 00007ffa7da163c0  

DML/NORMAL Y{as} 64bit : '  

DML/NORMAL Y{as} 32value : '  

DML/NORMAL Y{ps} 64bit : '  

DML/NORMAL Y{ps} 32value : '  

DML/NORMAL Y{l}: [d:\th\minkernel\kernelbase\debug.c @ 443]

```

Args [in]

Specifies additional parameters that represent values to be inserted into the output during formatting. *Args* must be initialized using `va_start`. This method does not call `va_end`.

Return value

Return code	Description
S_OK	The method was successful.

This method may also return error values. See [Return Values](#) for more details.

Remarks

When generating very large output strings, it is possible to reach the limits of the debugger engine or of the operating system. For example, some versions of the debugger engine have a 16K character limit for a single output. If you find that very large output is getting truncated, you might need to split your output into multiple requests.

The macros `va_list`, `va_start`, and `va_end` are defined in `Stdarg.h`.

Requirements

Target platform

Header `Dbgeng.h` (include `Dbgeng.h` or `Stdarg.h`)

IDebugControl::Disassemble method

The **Disassemble** method disassembles a processor instruction in the target's memory.

Syntax

C++

```

HRESULT Disassemble(
    [in]          ULONG64  Offset,

```

```
[in]          ULONG    Flags,
[out, optional] PSTR    Buffer,
[in]          ULONG    BufferSize,
[out, optional] PULONG   DisassemblySize,
[out]          PULONG64 EndOffset
);
```

Parameters

Offset [in]

Specifies the location in the target's memory of the instruction to disassemble.

Flags [in]

Specifies the bit-flags that affect the behavior of this method. Currently the only flag that can be set is DEBUG_DISASM_EFFECTIVE_ADDRESS; when set, the engine will compute the effective address from the current register information and display it.

Buffer [out, optional]

Receives the disassembled instruction. If *Buffer* is **NULL**, this information is not returned.

BufferSize [in]

Specifies the size, in characters, of the *Buffer* buffer.

DisassemblySize [out, optional]

Receives the size, in characters, of the disassembled instruction. If *DisassemblySize* is **NULL**, this information is not returned.

EndOffset [out]

Receives the location in the target's memory of the instruction following the disassembled instruction.

Return value

This method can also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
S_FALSE	The method was successful. However, <i>Buffer</i> was too small to hold the disassembled instruction and the instruction was truncated to fit.

Remarks

The assembly language depends on the effective processor type of the target system. For information about the assembly language, see the processor documentation.

The disassembly options--returned by [GetAssemblyOptions](#)--affect the operation of this method.

For an overview of using assembly in debugger applications, see [Debugging in Assembly Mode](#). For more information about using assembly with the debugger engine API, see [Assembling and Disassembling Instructions](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugControl::Evaluate method

The **Evaluate** method evaluates an expression, returning the result.

Syntax

```
C++
HRESULT Evaluate(
    [in]          PCSTR      Expression,
    [in]          ULONG       DesiredType,
    [out]         PDEBUG_VALUE Value,
    [out, optional] PULONG     RemainderIndex
);
```

Parameters

Expression [in]

Specifies the expression to be evaluated.

DesiredType [in]

Specifies the desired return type. Possible values are described in [DEBUG_VALUE](#); with the addition of DEBUG_VALUE_INVALID, which indicates that the return type should be the expression's natural type.

Value [out]

Receives the value of the expression.

RemainderIndex [out, optional]

Receives the index of the first character of the expression not used in the evaluation. If *RemainderIndex* is NULL, this information isn't returned.

Return value

This method may also return other error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
E_FAIL	An error occurred while evaluating the expression. For example, there was a syntax error, an undefined variable, or a division by zero exception.

Remarks

Expressions are evaluated by the current *expression evaluator*. The engine contains multiple expression evaluators; each supports a different syntax. The current expression evaluator can be chosen by using [SetExpressionSyntax](#).

For details of the available expression evaluators and their syntaxes, see [Numerical Expression Syntax](#).

If an error occurs while evaluating the expression, returning E_FAIL, the *RemainderIndex* variable can be used to determine approximately where in the expression the error occurred.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugControl::Execute method

The **Execute** method executes the specified debugger commands.

Syntax

```
C++

HRESULT Execute(
    [in] ULONG OutputControl,
    [in] PCSTR Command,
    [in] ULONG Flags
);
```

Parameters

OutputControl [in]

Specifies the output control to use while executing the command. For possible values, see [DEBUG_OUTCTL_XXX](#). For more information about output, see [Input and Output](#).

Command [in]

Specifies the command string to execute. The command is interpreted like those typed into a debugger command window. This command string can contain multiple commands for the engine to execute. See [Debugger Commands](#) for the command reference.

Flags [in]

Specifies a bit field of execution options for the command. The default options are to log the command but to not send it to the output. The following table lists the bits that can be set.

Value	Description
DEBUG_EXECUTE_ECHO	The command string is sent to the output.
DEBUG_EXECUTE_NOT_LOGGED	The command string is not logged. This is overridden by DEBUG_EXECUTE_ECHO.
DEBUG_EXECUTE_NO_REPEAT	If <i>Command</i> is an empty string, do not repeat the last command, and do not save the current command string for repeat execution later.

Return value

This method can also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

This method executes the given command string. If the string has multiple commands, this method will not return until all of the commands have been executed. If the sequence of commands involves waiting for the target to execute, this method can take an arbitrary amount of time to complete.

Note It is important to understand what it means for a step command to execute. A step command initiates a stepping action but does not wait for the stepping to complete. For example, suppose you call **IDebugControl::Execute** and pass a command string that contains the single command **pet**. The **pet** command initiates a step to the next call or return instruction, but **pet** completes its execution before the stepping takes place. Consequently, **IDebugControl::Execute** returns before the stepping takes place. Trace and go commands behave in a similar way. Examples of commands that have this behavior include **g**, **gh**, **ta**, **tb**, **tet**, **pa**, and **pc**.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugControl::ExecuteCommandFile method

The **ExecuteCommandFile** method opens the specified file and executes the debugger commands that are contained within.

Syntax

```
C++
HRESULT ExecuteCommandFile(
    [in] ULONG OutputControl,
    [in] PCSTR CommandFile,
    [in] ULONG Flags
);
```

Parameters

OutputControl [in]

Specifies where to send the output of the command. For possible values, see [DEBUG_OUTCTL_XXX](#). For more information about output, see [Input and Output](#).

CommandFile [in]

Specifies the name of the file that contains the commands to execute. This file is opened for reading and its contents are interpreted as if they had been typed into the debugger console.

Flags [in]

Specifies execution options for the command. The default options are to log the command but not to send it to the output. For details about the values that *Flags* can take, see [Execute](#).

Return value

This method might also return error values, including error values caused by a failure to open the specified file. For more information, see [Return Values](#).

Return code	Description
S_OK	The method was successful.

Remarks

This method reads the specified file and execute the commands one line at a time using [Execute](#). If an exception occurred while executing a line, the execution will continue with the next line.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

IDebugControl::GetActualProcessorType method

The **GetActualProcessorType** method returns the processor type of the physical processor of the computer that is running the target.

Syntax

```
C++
HRESULT GetActualProcessorType(
    [out] PULONG Type
);
```

Parameters

Type [out]

Receives the type of the processor. The processor types are listed in the following table.

Value	Processor
IMAGE_FILE_MACHINE_I386	x86 architecture
IMAGE_FILE_MACHINE_ARM	ARM architecture

IMAGE_FILE_MACHINE_IA64 Intel Itanium architecture
IMAGE_FILE_MACHINE_AMD64 x64 architecture
IMAGE_FILE_MACHINE_EBC EFI byte code architecture

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

For more information, see [Target Information](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

IDebugControl::GetBreakpointById method

The **GetBreakpointById** method returns the breakpoint with the specified breakpoint ID.

Syntax

C++

```
HRESULT GetBreakpointById(
    [in]  ULONG           Id,
    [out] PDEBUG_BREAKPOINT *Bp
);
```

Parameters

Id [in]

Specifies the breakpoint ID of the breakpoint to return.

Bp [out]

Receives the breakpoint.

Return value

This method can also return other error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
E_NOINTERFACE	No breakpoint was found with the given ID, or the breakpoint with the specified ID does not belong to the current process, or the breakpoint with the given ID is private (see GetFlags).

Remarks

If the specified breakpoint does not belong to the current process, the method will fail.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugControl](#)
[IDebugControl2](#)
[IDebugControl3](#)
[IDebugBreakpoint](#)

[Send comments about this topic to Microsoft](#)

IDebugControl::GetBreakpointByIndex method

The **GetBreakpointByIndex** method returns the breakpoint located at the specified index.

Syntax

C++

```
HRESULT GetBreakpointByIndex(
    [in]    ULONG          Index,
    [out]   PDEBUG_BREAKPOINT *Bp
);
```

Parameters

Index [in]

Specifies the zero-based index of the breakpoint to return. This is specific to the current process. The value of *Index* should be between zero and the total number of breakpoints minus one. The total number of breakpoints can be determined by calling [GetNumberBreakpoints](#).

Bp [out]

Receives the returned breakpoint.

Return value

This method can also return other error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
E_NOINTERFACE	No breakpoint was found with the given index, or the breakpoint with the given index is private.

Remarks

The index and returned breakpoint are specific to the current process. The same index will return a different breakpoint if the current process is changed.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

IDebugControl::GetBreakpointParameters method

The **GetBreakpointParameters** method returns the parameters of one or more [breakpoints](#).

Syntax

```
C++  
HRESULT GetBreakpointParameters(  
    [in]           ULONG          Count,  
    [in, optional] PULONG         Ids,  
    [in]           ULONG          Start,  
    [out]          PDEBUG_BREAKPOINT_PARAMETERS Params  
) ;
```

Parameters

Count [in]

Specifies the number of breakpoints whose parameters are being requested.

Ids [in, optional]

Specifies an array containing the IDs of the breakpoints whose parameters are being requested. The number of items in this array must be equal to the value specified in *Count*. If *Ids* is **NULL**, *Start* is used instead.

Start [in]

Specifies the beginning index of the breakpoints whose parameters are being requested. The parameters for breakpoints with indices *Start* through *Start* plus *Count* minus one will be returned. *Start* is used only if *Ids* is **NULL**.

Params [out]

Receives the parameters for the specified breakpoints. The size of this array is equal to the value of *Count*. For details on the structure returned, see [DEBUG_BREAKPOINT_PARAMETERS](#).

Return value

This method can also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
S_FALSE	The method was successful. However, the parameters for some of the breakpoints were not returned. The parameters that were not returned have their Id field set to DEBUG_ANY_ID .

Remarks

Some of the parameters might not be returned. This happens if either a breakpoint could not be found or a breakpoint is private (see [GetFlags](#)).

Requirements

Target platform
Header Dbgeng.h (include Dbgeng.h, Dbgeng.h, or Dbgeng.h)

IDebugControl::GetCodeLevel method

The **GetCodeLevel** method returns the current code level and is mainly used when stepping through code.

Syntax

```
C++
HRESULT GetCodeLevel(
    [out] PULONG Level
);
```

Parameters

Level [out]

Receives the current code level. *Level* can take one of the values in the following table.

Value	Description
DEBUG_LEVEL_SOURCE	<i>Source mode</i> . When stepping through code on the target, the size of a single step will be a line of source code.
DEBUG_LEVEL_ASSEMBLY	<i>Assembly mode</i> . When stepping through code on the target, the size of a single step will be a single processor instruction.

Return value

This method can also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

For more information about the code level, see [Using Source Files](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

IDebugControl::GetDebuggeeType method

The `GetDebuggeeType` method describes the nature of the current target.

Syntax

```
C++
HRESULT GetDebuggeeType(
    [out] PULONG Class,
    [out] PULONG Qualifier
);
```

Parameters

Class [out]

Receives the class of the current target. It will be set to one of the values in the following table.

Value	Description
DEBUG_CLASS_UNINITIALIZED	There is no current target.
DEBUG_CLASS_KERNEL	The current target is a kernel-mode target.
DEBUG_CLASS_USER_WINDOWS	The current target is a user-mode target.

Qualifier [out]

Provides more details about the type of the target. Its interpretation depends on the value of *Class*. When class is DEBUG_CLASS_UNINITIALIZED, *Qualifier* returns zero. The following values are applicable for kernel-mode targets.

Value	Description
DEBUG_KERNEL_CONNECTION	The current target is a live kernel being debugged in the standard way (using a COM port, 1394 bus, or named pipe).
DEBUG_KERNEL_LOCAL	The current target is the local kernel.
DEBUG_KERNEL_EXDI_DRIVER	The current target is a live kernel connected using eXDI drivers.
DEBUG_KERNEL_SMALL_DUMP	The current target is a kernel-mode Small Memory Dump file.
DEBUG_KERNEL_DUMP	The current target is a kernel-mode Kernel Memory Dump file.
DEBUG_KERNEL_FULL_DUMP	The current target is a kernel-mode Complete Memory Dump file.

The following values are applicable for user-mode targets.

Value	Description
DEBUG_USER_WINDOWS_PROCESS	The current target is a user-mode process on the same computer as the debugger engine .
DEBUG_USER_WINDOWS_PROCESS_SERVER	The current target is a user-mode process connected using a process server.
DEBUG_USER_WINDOWS_SMALL_DUMP	The current target is a user-mode Minidump file.
DEBUG_USER_WINDOWS_DUMP	The current target is a Full User-Mode Dump file.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugControl::GetDisassembleEffectiveOffset method

The **GetDisassembleEffectiveOffset** method returns the address of the last instruction disassembled using [Disassemble](#).

Syntax

```
C++
HRESULT GetDisassembleEffectiveOffset(
    [out] PULONG64 Offset
);
```

Parameters

Offset [out]

Receives the address in the target's memory of the effective offset from the last instruction disassembled.

Return value

This method can also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

The effective offset is the memory location used by an instruction. For example, if the last instruction to be disassembled is `move ax, [ebp+4]`, the effective address is the value of `ebp+4`. This corresponds to the `$ea` pseudo-register.

For more information about using assembly with the debugger engine API, see [Assembling and Disassembling Instructions](#).

Requirements

Target platform

IDebugControl::GetEffectiveProcessorType method

The **GetEffectiveProcessorType** method returns the effective processor type of the processor of the computer that is running the target.

Syntax

C++

```
HRESULT GetEffectiveProcessorType(
    [out] PULONG Type
);
```

Parameters

Type [out]

Receives the type of the processor. For possible values, see the *Type* parameter in [GetActualProcessorType](#).

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

For more information, see [Target Information](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugControl::GetEngineOptions method

The **GetEngineOptions** method returns the engine's options.

Syntax

```
C++  
HRESULT GetEngineOptions(  
    [out] PULONG Options  
) ;
```

Parameters

Options [out]

Receives a bit-set that contains the engine's options. For a description of the engine options, see [DEBUG_ENGOPT_XXX](#).

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

IDebugControl::GetEventFilterCommand method

The **GetEventFilterCommand** method returns the debugger command that the engine will execute when a specified event occurs.

Syntax

```
C++  
HRESULT GetEventFilterCommand(  
    [in]          ULONG Index,  
    [out, optional] PSTR   Buffer,  
    [in]          ULONG BufferSize,  
    [out, optional] PULONG CommandSize  
) ;
```

Parameters

Index [in]

Specifies the index of the event filter. *Index* can take any value between zero and one less than the total number of event filters returned by [GetNumberEventFilters](#) (inclusive). For more information about the index of the filters, see [Index](#) and [Exception Code](#).

Buffer [out, optional]

Receives the debugger command that the engine will execute when the event occurs.

BufferSize [in]

Specifies the size, in characters, of the buffer that *Buffer* specifies.

CommandSize [out, optional]

Receives the size in characters of the command. If *CommandSize* is **NULL**, this information is not returned.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

For more information about event filters, see [Event Filters](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugControl::GetEventFilterText method

The `GetEventFilterText` method returns a short description of an event for a specific filter.

Syntax

```
C++  
HRESULT GetEventFilterText(  
    [in]          ULONG   Index,  
    [out, optional] PSTR    Buffer,  
    [in]          ULONG   BufferSize,  
    [out, optional] PULONG  TextSize  
) ;
```

Parameters

Index [in]

Specifies the index of the event filter whose description will be returned. Only the specific filters have a description attached to them; *Index* must refer to a specific filter.

Buffer [out, optional]

Receives the description of the specific filter.

BufferSize [in]

Specifies the size, in characters, of the buffer that *Buffer* specifies.

TextSize [out, optional]

Receives the size of the event description. If *TextSize* is **NULL**, this information is not returned.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
E_NOINTERFACE	<i>Index</i> did not refer to a specific filter. This can occur if <i>Index</i> refers to an arbitrary exception filter.

Remarks

For more information about [event filters](#), see [Event Filters](#).

IDebugControl::GetExceptionFilterParameters method

The **GetExceptionFilterParameters** method returns the parameters for exception filters specified by exception codes or by index.

Syntax

```
C++  
HRESULT GetExceptionFilterParameters(  
    [in]          ULONG             Count,  
    [in, optional] PULONG           Codes,  
    [in]          ULONG             Start,  
    [out]         PDEBUG_EXCEPTION_FILTER_PARAMETERS Params  
) ;
```

Parameters

Count [in]

Specifies the number of exception filters for which to return parameters.

Codes [in, optional]

Specifies an array of exception codes. The parameters for the exception filters with these exception codes will be returned. If *Codes* is **NULL**, *Start* is used instead.

Start [in]

Specifies the index of the first exception filter. The parameters for the exception filters starting at *Start* will be returned. If *Codes* is not **NULL**, *Start* is ignored.

Params [out]

Receives the parameters for the exception filters specified by *Codes* or *Start*. *Params* is an array of elements of type [DEBUG EXCEPTION FILTER PARAMETERS](#).

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

For more information about [event filters](#), see [Event Filters](#).

Requirements

Target platform

IDebugControl::GetExceptionFilterSecondCommand method

The **GetExceptionFilterSecondCommand** method returns the command that will be executed by the [debugger engine](#) upon the second chance of a specified exception.

Syntax

```
C++
HRESULT GetExceptionFilterSecondCommand(
    [in]           ULONG   Index,
    [out, optional] PSTR    Buffer,
    [in]           ULONG   BufferSize,
    [out, optional] PULONG  CommandSize
);
```

Parameters

Index [in]

Specifies the index of the exception filter whose second-chance command will be returned. *Index* can also refer to the default exception filter to return the second-chance command for those exceptions that do not have a specific or arbitrary exception filter.

Buffer [out, optional]

Receives the second-chance command for the exception filter.

BufferSize [in]

Specifies the size, in characters, of the buffer that *Buffer* specifies.

CommandSize [out, optional]

Receives the size, in characters, of the second-chance command for the exception filter. If *CommandSize* is **NULL**, this information is not returned.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

Only exception filters support a second-chance command. If *Index* refers to a [specific event filter](#), the command returned to *Buffer* will be empty. The returned command will also be empty if no second-chance command has been set for the specified exception.

For more information about [event filters](#), see [Event Filters](#).

IDebugControl::GetExecutingProcessorType method

The **GetExecutingProcessorType** method returns the executing processor type for the processor for which the last event occurred.

Syntax

C++

```
HRESULT GetExecutingProcessorType(
    [out] PULONG Type
);
```

Parameters

Type [out]

Receives the processor type. See [GetActualProcessorType](#) for a list of possible values this parameter can receive.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

For more information, see [Target Information](#).

Requirements

Target platform

IDebugControl::GetExecutionStatus method

The **GetExecutionStatus** method returns information about the execution status of the [debugger engine](#).

Syntax

C++

```
HRESULT GetExecutionStatus(
    [out] PULONG Status
);
```

Parameters

Status [out]

Receives the execution status. This will be set to one of the values in the following table. Note that the description of these values differs slightly from the description in [DEBUG_STATUS_XXX](#).

Value	Description
DEBUG_STATUS_NO_DEBUGGEE	The engine is not attached to a target.

DEBUG_STATUS_STEP_OVER	The target is currently executing a single instruction. If that instruction is a subroutine call, the entire call will be executed.
DEBUG_STATUS_STEP_INTO	The target is currently executing a single instruction.
DEBUG_STATUS_STEP_BRANCH	The target is currently running until it encounters a branch instruction.
DEBUG_STATUS_GO	The target is currently running normally. It will continue normal execution until an event occurs.
DEBUG_STATUS_BREAK	The target is not running.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

For more information, see [Target Information](#).

Requirements

Target platform

IDebugControl::GetExtensionByPath method

The **GetExtensionByPath** method returns the handle for an already loaded extension library.

Syntax

```
C++
HRESULT GetExtensionByPath(
    [in]  PCSTR    Path,
    [out] PULONG64 Handle
);
```

Parameters

Path [in]

Specifies the fully qualified path and file name of the extension library.

Handle [out]

Receives the handle of the extension library.

Return value

This method can also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

Extension libraries are loaded into the [host engine](#), which is where this method looks for the requested extension library. *Path* is a path and file name for the host engine.

For more information on using extension libraries, see [Calling Extensions and Extension Functions](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugControl](#)

IDebugControl::GetExtensionFunction method

The **GetExtensionFunction** method returns a pointer to an extension function from an extension library.

Syntax

```
C++  
HRESULT GetExtensionFunction(  
    [in]    ULONG64 Handle,  
    [in]    PCSTR    FuncName,  
    [out]   FARPROC *Function  
) ;
```

Parameters

Handle [in]

Specifies the handle of the extension library that contains the extension function. If *Handle* is zero, the engine will walk the extension library chain searching for the extension function.

FuncName [in]

Specifies the name of the extension function to return. When searching the extension libraries for the function, the debugger engine will prepend "_EFN_" to the name. For example, if *FuncName* is "SampleFunction", the engine will search the extension libraries for "_EFN_SampleFunction".

Function [out]

Receives the extension function.

Return value

This method can also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

Extension libraries are loaded into the host engine and extension functions cannot be called remotely. The current client must not be a debugging client, it must belong to the host engine.

The extension function can have any function prototype. In order for any program to call this extension function, the extension function should be cast to the correct prototype.

For more information on using extension functions, see [Calling Extensions and Extension Functions](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugControl::GetInterrupt method

The **GetInterrupt** method checks whether a user interrupt was issued.

Syntax

C++

```
HRESULT GetInterrupt();
```

Parameters

This method has no parameters.

Return value

Return code	Description
S_OK	The method was successful and an interrupt has been requested.
S_FALSE	The method was successful and an interrupt was not requested.

This method may also return error values. See [Return Values](#) for more details.

Remarks

If a user interrupt was issued, it is cleared when this method is called.

Examples of user interrupts include pressing Ctrl+C or pressing the **Stop** button in a debugger. Calling [SetInterrupt](#) also causes a user interrupt.

Note It is recommended that debugger extensions call **GetInterrupt** while undertaking long tasks.

This method can be called at any time and from any thread.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugControl](#)
[IDebugControl2](#)
[IDebugControl3](#)
[SetInterrupt](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugControl::GetInterruptTimeout method

The **GetInterruptTimeout** method returns the number of seconds that the engine will wait when requesting a break into the debugger.

Syntax

C++

```
HRESULT GetInterruptTimeout(
    [out] PULONG Seconds
);
```

Parameters

Seconds [out]

Receives the number of seconds that the engine will wait for the target when requesting a break into the debugger.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

The engine requests a break into the debugger when [SetInterrupt](#) is called with DEBUG_INTERRUPT_ACTIVE. If this interrupt times out, the engine will generate a synthetic exception event. This event will be sent to [event callback objects](#)'s [IDebugEventCallbacks::Exception](#) method.

Most targets do not support interrupt time-outs. Live user-mode debugging is one of the targets that does support them.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

IDebugControl::GetLastEventInformation method

The [GetLastEventInformation](#) method returns information about the last event that occurred in a target.

Syntax

C++

```
HRESULT GetLastEventInformation(
    [out]          PULONG Type,
    [out]          PULONG ProcessId,
    [out]          PULONG ThreadId,
    [out, optional] PVOID  ExtraInformation,
    [in]           ULONG  ExtraInformationSize,
    [out, optional] PULONG ExtraInformationUsed,
    [out, optional] PSTR   Description,
    [in]           ULONG  DescriptionSize,
    [out, optional] PULONG DescriptionUsed
);
```

Parameters

Type [out]

Receives the type of the last event generated by the target. For a list of possible types, see [DEBUG_EVENT_XXX](#).

ProcessId [out]

Receives the process ID of the process in which the event occurred. If this information is not available, DEBUG_ANY_ID will be returned instead.

ThreadId [out]

Receives the thread index (not the thread ID) of the thread in which the last event occurred. If this information is not available, DEBUG_ANY_ID will be returned instead.

ExtraInformation [out, optional]

Receives extra information about the event. The contents of this extra information depends on the type of the event. If *ExtraInformation* is **NULL**, this information is not returned.

ExtraInformationSize [in]

Specifies the size, in bytes, of the buffer that *ExtraInformation* specifies.

ExtraInformationUsed [out, optional]

Receives the size, in bytes, of extra information. If *ExtraInformationUsed* is **NULL**, this information is not returned.

Description [out, optional]

Receives the description of the event. If *Description* is **NULL**, this information is not returned.

DescriptionSize [in]

Specifies the size, in characters, of the buffer that *Description* specifies.

DescriptionUsed [out, optional]

Receives the size in characters of the description of the event. If *DescriptionUsed* is **NULL**, this information is not returned.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
S_FALSE	The method was successful. However, either <i>ExtraInformationSize</i> or <i>DescriptionSize</i> were smaller than the size of the respective data or string and the data or string was truncated to fit inside the buffer.

Remarks

For thread and process creation events, the thread index and process ID returned to *ThreadId* and *ProcessId* are for the newly created thread or process.

For more information about the last event, see the topic [Event Information](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

IDebugControl::GetLogFile method

The **GetLogFile** method returns the name of the currently open log file.

Syntax

C++

```
HRESULT GetLogFile(
    [out, optional] PSTR    Buffer,
    [in]          ULONG   BufferSize,
    [out, optional] PULONG  FileSize,
    [out]          PBOOL   Append
);
```

Parameters

Buffer [out, optional]

Receives the name of the currently open log file. If *Buffer* is **NULL**, this information is not returned.

BufferSize [in]

Specifies the size, in characters, of the *Buffer* buffer.

FileSize [out, optional]

Receives the size, in characters, of the name of the log file. If *FileSize* is **NULL**, this information is not returned.

Append [out]

Receives **TRUE** if log messages are appended to the log file, or **FALSE** if the contents of the log file were discarded when the file was opened.

Return value

This method can also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
S_FALSE	The method was successful. However, the name of the log file was too long to fit in the <i>Buffer</i> buffer so the name was truncated.
E_NOINTERFACE	There is no currently open log file.

Remarks

GetLogFile and **GetLogFileWide** behave the same way as [GetLogFile2](#) and [GetLogFile2Wide](#) with *Append* receiving only the information about the DEBUG_LOG_APPEND flag.

For more information about log files, see [Using Input and Output](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

IDebugControl::GetLogMask method

The **GetLogMask** method returns the output mask for the currently open log file.

Syntax

```
C++
HRESULT GetLogMask(
    [out] PULONG Mask
);
```

Parameters

Mask [out]

Receives the output mask for the log file. See [DEBUG_OUTPUT_XXX](#) for details about how to interpret this value.

Return value

This method can also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

For more information about log files, see [Using Input and Output](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugControl](#)

IDebugControl::GetNearInstruction method

The **GetNearInstruction** method returns the location of a processor instruction relative to a given location.

Syntax

C++

```
HRESULT GetNearInstruction(
    [in]     ULONG64  Offset,
    [in]     LONG      Delta,
    [out]    PULONG64  NearOffset
);
```

Parameters

Offset [in]

Specifies the location in the process's virtual address space from which to start looking for the desired instruction.

Delta [in]

Specifies the number of instructions from *Offset* of the desired instruction. If *Delta* is negative, the returned offset is before *Offset* (see the Remarks section for more information).

NearOffset [out]

Receives the location in the process's virtual address space of the instruction that is *Delta* instructions away from *Offset*.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

On some architectures, like x86 and x64, the size of an instruction may vary. On these architectures, when *Delta* is negative, the desired instruction location might not be uniquely defined. In this case, the [debugger engine](#) will search backward from *Offset* until it encounters a location such that there are the *Delta* number of instructions between that location and *Offset*.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugControl::GetNotifyEventHandle method

The **GetNotifyEventHandle** method receives the handle of the event that will be signaled after the next *exception* in a target.

Syntax

```
C++  
HRESULT GetNotifyEventHandle(  
    [out] PULONG64 Handle  
) ;
```

Parameters

Handle [out]

Receives the handle of the event that will be signaled. If *Handle* is **NULL**, no event will be signaled.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

If an event to be signaled was set and an exception occurs in a target, when the engine resumes execution in the target again, the event will be signaled.

The event will only be signaled once. After it has been signaled, this method will return **NULL** to *Handle*, unless [SetNotifyEventHandle](#) is called to set another event to signal.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugControl::GetNumberBreakpoints method

The **GetNumberBreakpoints** method returns the number of [breakpoints](#) for the current process.

Syntax

```
C++  
HRESULT GetNumberBreakpoints(  
    [out] PULONG Number  
) ;
```

Parameters

Number [out]

Receives the number of breakpoints.

Return value

This method can also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugControl::GetNumberEventFilters method

The **GetNumberEventFilters** method returns the number of [event filters](#) currently used by the engine.

Syntax

C++

```
HRESULT GetNumberEventFilters(
    [out] PULONG SpecificEvents,
    [out] PULONG SpecificExceptions,
    [out] PULONG ArbitraryExceptions
);
```

Parameters

SpecificEvents [out]

Receives the number of [events](#) that can be controlled using the specific event filters. These events are enumerated using some of the [DEBUG FILTER XXX](#) constants.

SpecificExceptions [out]

Receives the number of *exceptions* that can be controlled using the specific exception filters. The first specific exception filter is the default exception filter. The exceptions controlled by the other specific exception filters will always have their own filter and will not inherit their behavior from the default specific exception filter. These exception filters are identified by their exception code. See [Specific Exceptions](#) for a list of the specific exception filters.

ArbitraryExceptions [out]

Receives the number of arbitrary exception filters currently used by the engine. These exception filters are identified by their exception code.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

For more information about event filters, see [Event Filters](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugControl::GetNumberPossibleExecutingProcessorTypes method

The **GetNumberPossibleExecutingProcessorTypes** method returns the number of processor types that are supported by the computer running the current target.

Syntax

C++

```
HRESULT GetNumberPossibleExecutingProcessorTypes (
    [out] PULONG Number
);
```

Parameters

Number [out]

Receives the number of processor types.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

For more information, see [Target Information](#).

Requirements

IDebugControl::GetNumberProcessors method

The **GetNumberProcessors** method returns the number of processors on the computer running the current target.

Syntax

C++

```
HRESULT GetNumberProcessors (
    [out] PULONG Number
);
```

Parameters

Number [out]

Receives the number of processors.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

For more information, see [Target Information](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

IDebugControl::GetNumberSupportedProcessorTypes method

The GetNumberSupportedProcessorTypes method returns the number of processor types supported by the engine.

Syntax

C++

```
HRESULT GetNumberSupportedProcessorTypes(
    [out] PULONG Number
);
```

Parameters

Number [out]

Receives the number of processor types.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

For more information, see [Target Information](#).

IDebugControl::GetPageSize method

The **GetPageSize** method returns the page size for the effective processor mode.

Syntax

```
C++  
HRESULT GetPageSize(  
    [out] PULONG Size  
) ;
```

Parameters

Size [out]

Receives the page size.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugControl::GetPossibleExecutingProcessorTypes method

The **GetPossibleExecutingProcessorTypes** method returns the processor types that are supported by the computer running the current target.

Syntax

```
C++  
HRESULT GetPossibleExecutingProcessorTypes(  
    [in] ULONG Start,  
    [in] ULONG Count,  
    [out] PULONG Types  
) ;
```

Parameters

Start [in]

Specifies the index of the first processor type to return. The processor types are indexed by numbers zero through to the number of processor types supported by the current target minus one. The number of processor types supported by the current target can be found using [GetNumberPossibleExecutingProcessorTypes](#).

Count [in]

Specifies how many processor types to return.

Types [out]

Receives the list of processor types. The number of elements this array holds is *Count*. For a description of the processor types see [GetActualProcessorType](#).

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

For more information, see [Target Information](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugControl::GetProcessorTypeNames method

The **GetProcessorTypeNames** method returns the full name and abbreviated name of the specified processor type.

Syntax

```
C++  
HRESULT GetProcessorTypeNames(  
    [in]           ULONG Type,  
    [out, optional] PSTR  FullNameBuffer,  
    [in]           ULONG FullNameBufferSize,  
    [out, optional] PULONG FullNameSize,  
    [out, optional] PSTR  AbbrevNameBuffer,  
    [in]           ULONG AbbrevNameBufferSize,  
    [out, optional] PULONG AbbrevNameSize  
) ;
```

Parameters

Type [in]

Specifies the type of the processor whose name is requested. See [GetActualProcessorType](#) for a list of possible values.

FullNameBuffer [out, optional]

Receives the full name of the processor type. If *FullNameBuffer* is **NULL**, this information is not returned.

FullNameBufferSize [in]

Specifies the size, in characters, of the buffer that *FullNameBuffer* specifies.

FullNameSize [out, optional]

Receives the size in characters of the full name of the processor type. If *FullNameSize* is **NULL**, this information is not returned.

AbbrevNameBuffer [out, optional]

Receives the abbreviated name of the processor type. If *AbbrevNameBuffer* is **NULL**, this information is not returned.

AbbrevNameBufferSize [in]

Specifies the size, in characters, of the buffer that *AbbrevNameBuffer* specifies.

AbbrevNameSize [out, optional]

Receives the size in characters of the abbreviated name of the processor type. If *AbbrevNameSize* is **NULL**, this information is not returned.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
S_FALSE	The method was successful. However, at least one of <i>FullNameBuffer</i> or <i>AbbrevNameBuffer</i> was too small for the corresponding name, so the name was truncated.

Remarks

For more information, see [Target Information](#).

Requirements

Target platform

IDebugControl::GetPromptText method

The **GetPromptText** method returns the standard prompt text that will be prepended to the formatted output specified in the *OutputPrompt* and *OutputPromptVaList* methods.

Syntax

```
C++
HRESULT GetPromptText(
    [out, optional] PSTR    Buffer,
    [in]          ULONG   BufferSize,
    [out, optional] PULONG  TextSize
);
```

Parameters

Buffer [out, optional]

Receives the prompt text. If *Buffer* is **NULL**, this information is not returned.

BufferSize [in]

Specifies the size, in characters, of the *Buffer* buffer.

TextSize [out, optional]

Receives the size, in characters, of the prompt text. If *TextSize* is **NULL**, this information is not returned.

Return value

This method can also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
S_FALSE	The method was successful. However, the prompt text was too large to fit into the <i>Buffer</i> buffer and the text was truncated.

Remarks

For more information about prompting the user, see [Using Input and Output](#).

IDebugControl::GetRadix method

The **GetRadix** method returns the default radix (number base) used by the [debugger engine](#) when it evaluates and displays MASM expressions, and when it displays symbol information.

Syntax

C++
HRESULT GetRadix(
 [out] PULONG Radix
) ;

Parameters

Radix [out]

Receives the default radix.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

For more information about the default radix, see [Using Input and Output](#).

IDebugControl::GetReturnOffset method

The **GetReturnOffset** method returns the return address for the current function.

Syntax

```
C++
HRESULT GetReturnOffset(
    [out] PULONG64 Offset
);
```

Parameters

Offset [out]

Receives the return address.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

The return address is the location in the process's virtual address space of the instruction that will be executed when the current function returns.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

IDebugControl::GetSpecificFilterArgument method

The **GetSpecificFilterArgument** method returns the value of filter argument for the specific filters that have an argument.

Syntax

```
C++
HRESULT GetSpecificFilterArgument(
    [in]          ULONG   Index,
    [out, optional] PSTR    Buffer,
    [in]          ULONG   BufferSize,
    [out, optional] PULONG  ArgumentSize
);
```

Parameters

Index [in]

Specifies the index of the specific filter whose argument will be returned. *Index* must be the index of a specific filter that has an argument.

Buffer [out, optional]

Receives the argument for the specific filter. The interpretation of the argument depends on the specific filter.

BufferSize [in]

Specifies the size, in characters, of the buffer that *Buffer* specifies.

ArgumentSize [out, optional]

Receives the size, in characters, of the argument for the specific filter.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
E_INVALIDARG	<i>Index</i> does not refer to a specific filter that has an argument.

Remarks

For a list of specific filters that have argument and the interpretation of those arguments, see [Event Filters](#).

IDebugControl::GetSpecificFilterParameters method

The **GetSpecificFilterParameters** method returns the parameters for specific event filters.

Syntax

```
C++  
HRESULT GetSpecificFilterParameters(  
    [in]  ULONG             Start,  
    [in]  ULONG             Count,  
    [out] PDEBUG_SPECIFIC_FILTER_PARAMETERS Params  
) ;
```

Parameters

Start [in]

Specifies the index of the first specific event filter whose parameters will be returned.

Count [in]

Specifies the number of specific event filters to return parameters for.

Params [out]

Receives the parameters for the specific event filters. *Params* is an array of elements of type [DEBUG_SPECIFIC_FILTER_PARAMETERS](#).

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

For more information about [event filters](#), see [Event Filters](#).

IDebugControl::GetStackTrace method

The **GetStackTrace** method returns the frames at the top of the specified call stack.

Syntax

```
C++  
HRESULT GetStackTrace(  
    [in]          ULONG64      FrameOffset,  
    [in]          ULONG64      StackOffset,  
    [in]          ULONG64      InstructionOffset,  
    [out]         PDEBUG_STACK_FRAME Frames,  
    [in]          ULONG        FrameSize,  
    [out, optional] PULONG     FramesFilled  
) ;
```

Parameters

FrameOffset [in]

Specifies the location of the stack frame at the top of the stack. If *FrameOffset* is set to zero, the current frame pointer is used instead.

StackOffset [in]

Specifies the location of the current stack. If *StackOffset* is set to zero, the current stack pointer is used instead.

InstructionOffset [in]

Specifies the location of the instruction of interest for the function that is represented by the stack frame at the top of the stack. If *InstructionOffset* is set to zero, the current instruction is used instead.

Frames [out]

Receives the stack frames. The number of elements this array holds is *FrameSize*.

FrameSize [in]

Specifies the number of items in the *Frames* array.

FramesFilled [out, optional]

Receives the number of frames that were placed in the array *Frames*. If *FramesFilled* is **NULL**, this information is not returned.

Return value

This method may also return other error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
E_FAIL	No stack frames were returned.

Remarks

The stack trace returned to *Frames* can be printed using [OutputStackTrace](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugControl::GetSupportedProcessorTypes method

The **GetSupportedProcessorTypes** method returns the processor types supported by the [debugger engine](#).

Syntax

```
C++  
HRESULT GetSupportedProcessorTypes(  
    [in]    ULONG Start,  
    [in]    ULONG Count,  
    [out]   PULONG Types  
) ;
```

Parameters

Start [in]

Specifies the index of the first processor type to return. The supported processor types are indexed by the numbers zero through the number of supported processor types minus one. The number of supported processor types can be found using [GetNumberSupportedProcessorTypes](#).

Count [in]

Specifies the number of processor types to return.

Types [out]

Receives the list of processor types. The number of elements this array holds is *Count*. For a description of the processor types, see [GetActualProcessorType](#).

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

For more information, see [Target Information](#).

Requirements

Target platform
Header Dbgeng.h (include Dbgeng.h)

See also

IDebugControl::GetSystemErrorControl method

The **GetSystemErrorControl** method returns the control values for handling system errors.

Syntax

```
C++  
HRESULT GetSystemErrorControl(  
    [out] PULONG OutputLevel,  
    [out] PULONG BreakLevel  
) ;
```

Parameters

OutputLevel [out]

Receives the level at which system errors are printed to the engine's output. If the level of the system error is less than or equal to *OutputLevel*, the error is printed to the debugger console.

BreakLevel [out]

Receives the level at which system errors break into the debugger. If the level of the system error is less than or equal to *BreakLevel*, the error breaks into the debugger.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

The level of a system error can take one of the following three values, listed from lowest to highest: SLE_ERROR, SLE_MINORERROR, and SLE_WARNING. These values are defined in Winuser.h.

When a system error occurs, the engine calls the [IDebugEventCallbacks::SystemError](#) method of the event callbacks. If the level is less than or equal to *BreakLevel*, the error will break into the debugger. If the level is greater than *BreakLevel*, the engine will proceed with execution in the target as indicated by the [IDebugEventCallbacks::SystemError](#) method calls. For more information about how the engine proceeds after an event, see [Monitoring Events](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

IDebugControl::GetSystemVersion method

The **GetSystemVersion** method returns information that identifies the operating system on the computer that is running the current target.

Syntax

```
C++  
HRESULT GetSystemVersion(  
    [out] PULONG PlatformId,  
    [out] PULONG Major,  
    [out] PULONG Minor,  
    [out, optional] PSTR ServicePackString,  
    [in] ULONG ServicePackStringSize,  
    [out, optional] PULONG ServicePackStringUsed,  
    [out] PULONG ServicePackNumber,  
    [out, optional] PSTR BuildString,
```

```
[in]          ULONG BuildStringSize,
[out, optional] PULONG BuildStringUsed
);
```

Parameters

PlatformId [out]

Receives the platform ID. *PlatformId* is always VER_PLATFORM_WIN32_NT for NT-based Windows.

Major [out]

Receives 0xF if the target's operating system is a *free build*, or 0xC if the operating system is a *checked build*.

Minor [out]

Receives the build number for the target's operating system.

ServicePackString [out, optional]

Receives the string for the service pack level of the target computer. If *ServicePackString* is **NULL**, this information is not returned. If no service pack is installed, *ServicePackString* can be empty.

ServicePackStringSize [in]

Specifies the size, in characters, of the buffer that *ServicePackString* specifies.

ServicePackStringUsed [out, optional]

Receives the size, in characters, of the string of the service pack level. If *ServicePackStringUsed* is **NULL**, this information is not returned.

ServicePackNumber [out]

Receives the service pack level of the target's operating system.

BuildString [out, optional]

Receives the string that identifies the build of the system. If *BuildString* is **NULL**, this information is not returned.

BuildStringSize [in]

Specifies the size, in characters, of the buffer that *BuildString* specifies.

BuildStringUsed [out, optional]

Receives the size, in characters, of the string that identifies the build. If *BuildStringUsed* is **NULL**, this information is not returned.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
S_FALSE	The method was successful. However, the <i>ServicePackString</i> buffer or the <i>BuildString</i> buffer were too small and the corresponding string was truncated.

Remarks

For more information, see [Target Information](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h or Ntddk.h)

See also

IDebugControl::GetTextMacro method

The **GetTextMacro** method returns the value of a fixed-name alias.

Syntax

C++

```
HRESULT GetTextMacro(
    [in]           ULONG   Slot,
    [out, optional] PSTR    Buffer,
    [in]           ULONG   BufferSize,
    [out, optional] PULONG MacroSize
);
```

Parameters

Slot [in]

Specifies the number of the fixed-name alias. *Slot* can take the values 0, 1, ..., 9, that represent the fixed-name aliases **\$u0**, **\$u1**, ..., **\$u9**.

Buffer [out, optional]

Receives the value of the alias specified by *Slot*. If *Buffer* is **NULL**, this information is not returned.

BufferSize [in]

Specifies the size, in characters, of the *Buffer* buffer.

MacroSize [out, optional]

Receives the size, in characters, of the value of the alias.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

Before executing commands or evaluating expressions, the debugger engine will replace the alias specified by *Slot* with the value of the alias (returned to the *Buffer* buffer).

For an overview of aliases used by the [debugger engine](#), see [Using Aliases](#). For more information about using aliases with the debugger engine API, see [Interacting with the Engine](#).

IDebugControl::GetWindbgExtensionApis64 method

The **GetWindbgExtensionApis64** method returns a structure that facilitates using the WdbgExts API.

Syntax

C++

```
HRESULT GetWindbgExtensionApis64(
    [in, out] PWINDBG_EXTENSION_APIS64 Api
);
```

Parameters

Api [in, out]

Receives a WINDBG_EXTENSION_APIS64 structure. This structure contains the functions used by the WdbgExts API. The **nSize** member of this structure must be set to the size of the structure before it is passed to this method.

Return value

This method may also return other error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
E_INVALIDARG	The value of <i>Api</i> -> nSize does not equal the size of the structure WINDBG_EXTENSION_APIS64.

Remarks

If you are including Wdbgexts.h in your extension code, you should call this method during the initialization of the extension DLL (see [DebugExtensionInitialize](#)).

Many WdbgExts functions are really macros. To ensure that these macros work correctly, the structure received by the *Api* parameter should be stored in a global variable named **ExtensionApis**.

The WINDBG_EXTENSION_APIS64 structure returned by this method serves the same purpose as the one provided to the callback function [WinDbgExtensionDlInit](#) (used by WdbgExts extensions).

For a list of the functions provided by the WdbgExts API, see [WdbgExts Functions](#).

Requirements

Target platform	
Header	Dbgeng.h (include Wdbgexts.h, Dbgeng.h, or Wdbgexts.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugControl::Input method

The **Input** method requests an input string from the [debugger engine](#).

Syntax

C++

```
HRESULT Input(
    [out]          PSTR     Buffer,
    [in]           ULONG    BufferSize,
    [out, optional] PULONG   InputSize
);
```

Parameters

Buffer [out]

Receives the input string from the engine.

BufferSize [in]

Specifies the size, in characters, of the buffer that *Buffer* specifies.

InputSize [out, optional]

Receives the number of characters returned in *Buffer*. If *InputSize* is **NULL**, this information is not returned.

Return value

Return code	Description
S_OK	The method was successful.
S_FALSE	The method was successful. However, the buffer was not big enough to hold the whole input string and it was truncated.

This method may also return error values. See [Return Values](#) for more details.

Remarks

For an overview of input in the debugger engine, see [Input and Output](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugControl](#)
[InputWide](#)

[Send comments about this topic to Microsoft](#)

IDebugControl::IsPointer64Bit method

The **IsPointer64Bit** method determines if the effective processor uses 64-bit pointers.

Syntax

```
C++
HRESULT IsPointer64Bit();
```

Parameters

This method has no parameters.

Return value

Return code	Description
S_OK	The effective processor uses 64-bit pointers.
S_FALSE	The effective processor does not use 64-bit pointers.

This method may also return error values. See [Return Values](#) for more details.

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugControl::OpenLogFile method

The **OpenLogFile** method opens a log file that will receive output from the [client objects](#).

Syntax

```
C++
HRESULT OpenLogFile(
    [in] PCSTR File,
    [in] BOOL Append
);
```

Parameters

File [in]

Specifies the name of the log file. *File* can include a relative or absolute path; relative paths are relative to the directory in which the debugger was started. If the file does not exist, it will be created.

Append [in]

Specifies whether or not to append log messages to an existing log file. If **TRUE**, log messages will be appended to the file; if **FALSE**, the contents of any existing file matching *File* are discarded.

Return value

This method can also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

OpenLogFile and **OpenLogFileWide** behave the same way as [OpenLogFile2](#) and [OpenLogFile2Wide](#) with *Flags* set to DEBUG_LOG_APPEND if *Append* is **TRUE** and DEBUG_LOG_DEFAULT otherwise.

Only one log file can be open at a time. If there is already a log file open, it will be closed.

For more information about log files, see [Using Input and Output](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

© 2016 Microsoft. All rights reserved.

IDebugControl::Output method

The **Output** method formats a string and send the result to output callbacks that have been registered with the engine's clients.

Syntax

```
C++  
HRESULT Output(  
    [in] ULONG Mask,  
    [in] PCSTR Format,  
    ...  
) ;
```

Parameters

Mask [in]

Specifies the output-type bit field. See [DEBUG_OUTPUT_XXX](#) for possible values.

Format [in]

Specifies the format string, as in **printf**. In general, conversion characters work exactly as in C. For the floating-point conversion characters the 64-bit argument is interpreted as a 32-bit floating-point number unless the **I** modifier is used.

The **%p** conversion character is supported, but it represents a pointer in a target's address space. It cannot have any modifiers and it uses the debugger's internal address

formatting. The following additional conversion characters are supported.

Character	Argument type	Argument	Text printed
%p	ULONG64	Pointer in an address space	The value of the pointer.
%N	DWORD_PTR (32 or 64 bits, depending on the host's architecture)	Pointer in the host's virtual address space	The value of the pointer. (This is equivalent to the standard C %p character.)
%I	ULONG64	Any 64-bit value	The specified value. If this is greater than 0xFFFFFFFF, it is printed as a 64-bit value. Otherwise, it is printed as a 32-bit value.
%ma	ULONG64	Address of a NULL-terminated ASCII string in the process's virtual address space	The specified string.
%mu	ULONG64	Address of a NULL-terminated Unicode string in the process's virtual address space	The specified string.
%msa	ULONG64	Address of an ANSI_STRING structure in the process's virtual address space	The specified string.
%msu	ULONG64	Address of a UNICODE_STRING structure in the process's virtual address space	The specified string.
%y	ULONG64	Address in the process's virtual address space of an item with symbol information	String that contains the name of the specified symbol (and displacement, if any).
%ly	ULONG64	Address in the process's virtual address space of an item with symbol information	String that contains the name of the specified symbol (and displacement, if any), as well as any available source line information.

...

Specifies additional parameters that contain values to be inserted into the output during formatting.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

When generating very large output strings, it is possible to reach the limits of the debugger engine or of the operating system. For example, some versions of the debugger engine have a 16K character limit for a single output. If you find that very large output is getting truncated, you might need to split your output into multiple requests.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugControl::OutputCurrentState method

The **OutputCurrentState** method prints the current state of the current target to the debugger console.

Syntax

```
C++
HRESULT OutputCurrentState(
    [in] ULONG OutputControl,
    [in] ULONG Flags
);
```

Parameters

OutputControl [in]

Specifies which clients to send the output to. For possible values see [DEBUG_OUTCTL_XXX](#).

Flags [in]

Specifies the bit set that determines the information to print to the debugger console. *Flags* can be any combination of values from the following table.

Flag	Description
DEBUG_CURRENT_SYMBOL	Symbol string for the address of the current instruction.
DEBUG_CURRENT_DISASM	Disassembly of the current instruction.
DEBUG_CURRENT_REGISTERS	Current register values.
DEBUG_CURRENT_SOURCE_LINE	File name and line number of the source corresponding to the current instruction.

Alternatively, *Flags* can be set to DEBUG_CURRENT_DEFAULT. This value includes all of the above flags.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

Setting the flags contained in *Flags* merely allows the information to be printed. The information will not always be printed (for example, it will not be printed if it is not available).

This is the same status information that is printed when breaking into the debugger.

For more information, see [Target Information](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugControl::OutputDisassembly method

The **OutputDisassembly** method disassembles a processor instruction and sends the disassembly to the [output callbacks](#).

Syntax

```
C++
HRESULT OutputDisassembly(
    [in] ULONG   OutputControl,
    [in] ULONG64 Offset,
    [in] ULONG   Flags,
    [out] PULONG64 EndOffset
);
```

Parameters

OutputControl [in]

Specifies the output control that determines which client's output callbacks receive the output. For possible values, see [DEBUG_OUTCTL_XXX](#). For more information about output, see [Input and Output](#).

Offset [in]

Specifies the location in the target's memory of the instruction to disassemble.

Flags [in]

Specifies the bit-flags that affect the behavior of this method. The following table lists the bits that can be set.

Bit-Flag	Effect when set
DEBUG_DISASM_EFFECTIVE_ADDRESS	Compute the effective address from the current register information and display it.
DEBUG_DISASM_MATCHING_SYMBOLS	If the address of the instruction has an exact symbol match, output the symbol.
DEBUG_DISASM_SOURCE_LINE_NUMBER	Include the source line number of the instruction in the output.
DEBUG_DISASM_SOURCE_FILE_NAME	Include the source file name in the output.

EndOffset [out]

Receives the location in the target's memory of the instruction that follows the disassembled instruction.

Return value

This method can also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

The assembly language depends on the effective processor type of the target system. For information about the assembly language, see the processor documentation.

For an overview of using assembly in debugger applications, see [Debugging in Assembly Mode](#). For more information about using assembly with the debugger engine API, see [Assembling and Disassembling Instructions](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugControl](#)

[IDebugControl3](#)
[Disassemble](#)
[OutputDisassemblyLines](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugControl::OutputDisassemblyLines method

The **OutputDisassemblyLines** method disassembles several processor instructions and sends the resulting assembly instructions to the [output callbacks](#).

Syntax

C++

```
HRESULT OutputDisassemblyLines(
    [in]          ULONG      OutputControl,
    [in]          ULONG      PreviousLines,
    [in]          ULONG      TotalLines,
    [in]          ULONG64    Offset,
    [in]          ULONG      Flags,
    [out, optional] PULONG    OffsetLine,
    [out, optional] PULONG64 StartOffset,
    [out, optional] PULONG64 EndOffset,
    [out, optional] PULONG64 LineOffsets
);
```

Parameters

OutputControl [in]

Specifies the output control that determines which client's output callbacks receive the output. For possible values, see [DEBUG_OUTCTL_XXX](#). For more information about output, see [Input and Output](#).

PreviousLines [in]

Specifies the number of lines of instructions before the instruction at *Offset* to include in the output. Typically, each instruction is output on a single line. However, some instructions can take up several lines of output; this can cause the number of lines output before the instruction at *Offset* to be greater than *PreviousLines*.

TotalLines [in]

Specifies the total number of lines of instructions to include in the output. Typically, each instruction is output on a single line. However, some instructions can take up several lines of output; this can cause the number of lines output to be greater than *TotalLines*.

Offset [in]

Specifies the location in the target's memory of the instructions to disassemble. The disassembly output will start *PreviousLines* lines before these processor instructions.

Flags [in]

Specifies the bit-flags that affect the behavior of this method. The following table lists the bits that can be set.

Bit-Flag	Effect when set
DEBUG_DISASM_EFFECTIVE_ADDRESS	Compute the effective address of each instruction from the current register information and output it.
DEBUG_DISASM_MATCHING_SYMBOLS	If the address of an instruction has an exact symbol match, output the symbol.
DEBUG_DISASM_SOURCE_LINE_NUMBER	Include the source line number of each instruction in the output.
DEBUG_DISASM_SOURCE_FILE_NAME	Include the source file name in the output.

OffsetLine [out, optional]

Receives the line number in the output that contains the instruction at *Offset*. If *OffsetLine* is **NULL**, this information is not returned.

StartOffset [out, optional]

Receives the location in the target's memory of the first instruction included in the output. If *StartOffset* is **NULL**, this information is not returned.

EndOffset [out, optional]

Receives the location in the target's memory of the instruction that follows the last disassembled instruction.

LineOffsets [out, optional]

Receives the locations in the target's memory of the instructions included in the output starting with the instruction at *Offset*. *LineOffsets* is an array that contains *TotalLines* elements.

Offset is the value of first entry in this array unless there was an error disassembling the instructions before this instruction. In this case, the first entry will contain DEBUG_ANY_ID and *Offset* will be placed in the second entry in the array (index one).

If the output for an instruction spans multiple lines, the element in the array that corresponds to the first line of the instruction will contain the address of the instruction.

If *LineOffsets* is **NULL**, this information is not returned.

Return value

This method can also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

The assembly language depends on the effective processor type of the target system. For information about the assembly language, see the processor documentation.

For an overview of using assembly in debugger applications, see [Debugging in Assembly Mode](#). For more information about using assembly with the debugger engine API, see [Assembling and Disassembling Instructions](#).

IDebugControl::OutputPrompt method

The **OutputPrompt** method formats and sends a user prompt to the [output callback objects](#).

Syntax

```
C++
HRESULT OutputPrompt(
    [in]          ULONG OutputControl,
    [in, optional] PCSTR Format,
    ...
);
```

Parameters

OutputControl [in]

Specifies an output control that determines which of the client's output callbacks will receive the output. For possible values, see [DEBUG_OUTCTL_XXX](#).

Format [in, optional]

Specifies the format string, as in **printf**. Typically, conversion characters work exactly as they do in C. For the floating-point conversion characters, the 64-bit argument is interpreted as a 32-bit floating-point number unless the **I** modifier is used.

The **%p** conversion character is supported, but it represents a pointer in a target's address space. It might not have any modifiers and it uses the debugger's internal address formatting. The following additional conversion characters are supported.

Character	Argument type	Argument	Text printed
%p	ULONG64	Pointer in an address space.	The value of the pointer.
%N	DWORD_PTR (32 or 64 bits, depending on the host's architecture)	Pointer in the host's virtual address space.	The value of the pointer. (This is equivalent to the standard C %p character.)
%I	ULONG64	Any 64-bit value.	The specified value. If this is greater than 0xFFFFFFFF, it is printed as a 64-bit value; otherwise, it is printed as a 32-bit value.
%ma	ULONG64	Address of a NULL-terminated ASCII string in the process' virtual address space.	The specified string.
%mu	ULONG64	Address of a NULL-terminated Unicode string in the process's virtual address space.	The specified string.
%msa	ULONG64	Address of an ANSI_STRING structure in the process's virtual address space.	The specified string.
%msu	ULONG64	Address of a UNICODE_STRING structure in the process's virtual address space.	The specified string.
%y	ULONG64	Address in the process's virtual address space of an item with symbol information.	String that contains the name of the specified symbol (and displacement, if any).
%ly	ULONG64	Address in the process's virtual address space of an item with symbol information.	String that contains the name of the specified symbol (and displacement, if any), as well as any available source line information.

If *Format* is **NULL**, only the standard prompt text is sent to the output callbacks.

...

Specifies additional parameters that represent values that are inserted into the output during formatting.

Return value

Return code	Description
S_OK	The method was successful.

This method can also return error values. See [Return Values](#) for more details.

Remarks

OutputPrompt and **OutputPromptWide** can be used to prompt the user for input.

The standard prompt will be sent to the output callbacks before the formatted text described by *Format*. The contents of the standard prompt is returned by the method [GetPromptText](#).

The prompt text is sent to the output callbacks with the [DEBUG_OUTPUT_PROMPT](#) output mask set.

For more information about prompting the user, see [Using Input and Output](#).

IDebugControl::OutputPromptVaList method

The [OutputPromptVaList](#) method formats and sends a user prompt to the [output callback objects](#).

Syntax

```
C++
HRESULT OutputPromptVaList(
    [in]        ULONG    OutputControl,
    [in, optional] PCSTR   Format,
    [in]        va_list Args
);
```

Parameters

OutputControl [in]

Specifies an output control that determines which of the client's output callbacks will receive the output. For possible values, see [DEBUG_OUTCTL XXX](#).

Format [in, optional]

Specifies the format string, as in **printf**. Typically, conversion characters work exactly as they do in C. For the floating-point conversion characters, the 64-bit argument is interpreted as a 32-bit floating-point number unless the **I** modifier is used.

The **%p** conversion character is supported, but it represents a pointer in a target's address space. It might not have any modifiers and it uses the debugger's internal address formatting. The following additional conversion characters are supported.

Character	Argument type	Argument	Text printed
%p	ULONG64	Pointer in an address space.	The value of the pointer.
%N	DWORD_PTR (32 or 64 bits, depending on the host's architecture)	Pointer in the host's virtual address space.	The value of the pointer. (This is equivalent to the standard C %p character.)
%I	ULONG64	Any 64-bit value.	The specified value. If this is greater than 0xFFFFFFFF, it is printed as a 64-bit value; otherwise, it is printed as a 32-bit value.
%ma	ULONG64	Address of a NULL-terminated ASCII string in the process's virtual address space.	The specified string.
%mu	ULONG64	Address of a NULL-terminated Unicode string in the process's virtual address space.	The specified string.
%msa	ULONG64	Address of an ANSI_STRING structure in the process's virtual address space.	The specified string.
%msu	ULONG64	Address of a UNICODE_STRING structure in the process's virtual address space.	The specified string.
%nsu	ULONG64	Address in the process's virtual address space of an item with symbol information.	String that contains the name of the specified symbol (and displacement, if any).
%y	ULONG64	Address in the process's virtual address space of an item with symbol information.	String that contains the name of the specified symbol (and displacement, if any), as well as any available source line information.
%ly	ULONG64		

If *Format* is **NULL**, only the standard prompt text is sent to the output callbacks.

Args [in]

Specifies additional parameters that represent values to be inserted into the output during formatting. *Args* must be initialized using `va_start`. This method does not call `va_end`.

Return value

This method can also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

`OutputPromptVaList` and `OutputPromptVaListWide` can be used to prompt the user for input.

The standard prompt will be sent to the output callbacks before the formatted text described by *Format*. The contents of the standard prompt is returned by the method [GetPromptText](#).

The prompt text is sent to the output callbacks with the [DEBUG_OUTPUT_PROMPT](#) output mask set.

For more information about prompting the user, see [Using Input and Output](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h or Stdarg.h)

See also

IDebugControl::OutputStackTrace method

The `OutputStackTrace` method outputs either the supplied stack frame or the current stack frames.

Syntax

```
C++  
HRESULT OutputStackTrace(  
    [in]           ULONG          OutputControl,  
    [in, optional] PDEBUG_STACK_FRAME Frames,  
    [in]           ULONG          FramesSize,  
    [in]           ULONG          Flags  
) ;
```

Parameters

OutputControl [in]

Specifies where to send the output. For possible values, see [DEBUG_OUTCTL_XXX](#).

Frames [in, optional]

Specifies the array of stack frames to output. The number of elements in this array is *FramesSize*. If *Frames* is **NULL**, the current stack frames are used.

FramesSize [in]

Specifies the number of frames to output.

Flags [in]

Specifies bit flags that determine what information to output for each frame. *Flags* can be any combination of values from the following table.

Flag	Description
DEBUG_STACK_ARGUMENTS	Displays the first three pieces of stack memory at the frame of each call. On platforms where parameters are passed on the stack, and the code for the frame uses stack arguments, these values will be the arguments to the function.
DEBUG_STACK_FUNCTION_INFO	Displays information about the function that corresponds to the frame. This includes calling convention and frame pointer omission (FPO) information.
DEBUG_STACK_SOURCE_LINE	Displays source line information for each frame of the stack trace.
DEBUG_STACK_FRAME_ADDRESSES	Displays the return address, previous frame address, and other relevant addresses for each frame.
DEBUG_STACK_COLUMN_NAMES	Displays column names.
DEBUG_STACK_NONVOLATILE_REGISTERS	Displays the non-volatile register context for each frame. This is only meaningful for some platforms.
DEBUG_STACK_FRAME_NUMBERS	Displays frame numbers.
DEBUG_STACK_PARAMETERS	Displays parameter names and values as given in symbol information.
DEBUG_STACK_FRAME_ADDRESSES_RA_ONLY	Displays just the return address in stack frame addresses.
DEBUG_STACK_FRAME_MEMORY_USAGE	Displays the number of bytes that separate the frames.
DEBUG_STACK_PARAMETERS_NEWLINE	Displays each parameter and its type and value on a new line.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

The array of stack frames can be obtained using [GetStackTrace](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugControl::OutputVaList method

The **OutputVaList** method formats a string and sends the result to the [output callbacks](#) that are registered with the engine's clients.

Syntax

```
C++
HRESULT OutputVaList(
    [in] ULONG Mask,
    [in] PCSTR Format,
    [in] va_list Args
);
```

Parameters

Mask [in]

Specifies the output-type bit field. See [DEBUG_OUTPUT_XXX](#) for possible values.

Format [in]

Specifies the format string, as in **printf**. Typically, conversion characters work exactly as they do in C. For the floating-point conversion characters, the 64-bit argument is interpreted as a 32-bit floating-point number unless the **I** modifier is used.

The `%p` conversion character is supported, but it represents a pointer in a target's address space. It might not have any modifiers, and it uses the debugger's internal address formatting. The following additional conversion characters are supported.

Character	Argument type	Argument	Text printed
<code>%p</code>	ULONG64	Pointer in an address space.	The value of the pointer.
<code>%N</code>	DWORD_PTR (32 or 64 bits, depending on the host's architecture)	Pointer in the host's virtual address space.	The value of the pointer. (This is equivalent to the standard C <code>%p</code> character.)
<code>%I</code>	ULONG64	Any 64-bit value.	The specified value. If this is greater than 0xFFFFFFFF, it is printed as a 64-bit value; otherwise, it is printed as a 32-bit value.
<code>%ma</code>	ULONG64	Address of a NULL-terminated ASCII string in the process's virtual address space.	The specified string.
<code>%mu</code>	ULONG64	Address of a NULL-terminated Unicode string in the process's virtual address space.	The specified string.
<code>%msa</code>	ULONG64	Address of an ANSI_STRING structure in the process's virtual address space.	The specified string.
<code>%msu</code>	ULONG64	Address of a UNICODE_STRING structure in the process's virtual address space.	The specified string.
<code>%y</code>	ULONG64	Address in the process's virtual address space of an item with symbol information.	String that contains the name of the specified symbol (and displacement, if any).
<code>%oly</code>	ULONG64	Address in the process's virtual address space of an item with symbol information.	String that contains the name of the specified symbol (and displacement, if any), as well as any available source line information.

Args [in]

Specifies additional parameters that represent values to be inserted into the output during formatting. `Args` must be initialized using `va_start`. This method does not call `va_end`.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
<code>S_OK</code>	The method was successful.

Remarks

When generating very large output strings, it is possible to reach the limits of the debugger engine or of the operating system. For example, some versions of the debugger engine have a 16K character limit for a single output. If you find that very large output is getting truncated, you might need to split your output into multiple requests.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h or Stdarg.h)

IDebugControl::OutputVersionInformation method

The `OutputVersionInformation` method prints version information about the [debugger engine](#) to the debugger console.

Syntax

C++

```
HRESULT OutputVersionInformation(
    [in] ULONG OutputControl
);
```

Parameters

OutputControl [in]

Specifies where to send the output. For possible values, see [DEBUG_OUTCTL_XXX](#).

Return value

This method may also return other error values, including error values caused by the engine being busy. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

The information that is sent to the output can include the mode of the debugger, the path and version of the debugger DLLs, the extension DLL search path, the extension DLL chain, and the version of the operating system that is running on the host computer.

For more information, see [Target Information](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugControl::ReadBugCheckData method

The **ReadBugCheckData** method reads the kernel bug check code and related parameters.

Syntax

```
C++
HRESULT ReadBugCheckData(
    [out] PULONG Code,
    [out] PULONG64 Arg1,
    [out] PULONG64 Arg2,
    [out] PULONG64 Arg3,
    [out] PULONG64 Arg4
);
```

Parameters

Code [out]

Receives the bug check code.

Arg1 [out]

Receives the first parameter associated with the bug check. The interpretation of this parameter depends on the bug check code.

Arg2 [out]

Receives the second parameter associated with the bug check. The interpretation of this parameter depends on the bug check code.

Arg3 [out]

Receives the third parameter associated with the bug check. The interpretation of this parameter depends on the bug check code.

Arg4 [out]

Receives the fourth parameter associated with the bug check. The interpretation of this parameter depends on the bug check code.

Return value

Return code	Description
S_OK	The method was successful.

This method can also return error values. See [Return Values](#) for more details.

Remarks

This method is only available in kernel-mode debugging.

For more information about bug checks, including a list of bug check codes and their interpretations, see [Bug Checks \(Blue Screens\)](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugControl::RemoveBreakpoint method

The **RemoveBreakpoint** method removes a breakpoint.

Syntax

```
C++  
HRESULT RemoveBreakpoint(  
    [in] PDEBUG_BREAKPOINT Bp  
) ;
```

Parameters

Bp [in]

Specifies an interface pointer to breakpoint to remove.

Return value

Return code	Description
S_OK	The method was successful.

This method may also return other error values. See [Return Values](#) for more details.

Remarks

After **RemoveBreakpoint** and **RemoveBreakpoint2** are called, the breakpoint object specified in the *Bp* parameter must not be used again.

Note Even though [IDebugBreakpoint](#) extends the COM interface [IUnknown](#), the lifetime of the breakpoint is not controlled using the [IUnknown](#) interface. Instead, the breakpoint is deleted after **RemoveBreakpoint** and **RemoveBreakpoint2** are called.

For more details, see [Using Breakpoints](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugControl::RemoveEngineOptions method

The **RemoveEngineOptions** method turns off some of the engine's options.

Syntax

```
C++  
HRESULT RemoveEngineOptions(  
    [in] ULONG Options  
) ;
```

Parameters

Options [in]

Specifies the engine options to turn off. *Options* is a bit-set; the new value of the engine's options will equal the bitwise-NOT of *Options* combined with old value using the bitwise-AND operator (*new_value* := *old_value* AND NOT *Options*). For a description of the engine options, see [DEBUG_ENGOPT_XXX](#).

Return value

Return code	Description
S_OK	The method was successful.

This method may also return error values. See [Return Values](#) for more details.

Remarks

After the engine options have been changed, the engine sends out notification to each client's event callback object by passing the DEBUG_CES_ENGINE_OPTIONS flag to the [IDebugEventCallbacks::ChangeEngineState](#) method.

Requirements

Target platform	
Header	Dbgeng.h (include Dbgeng.h, Dbgeng.h, or Dbgeng.h)

See also

IDebugControl::RemoveExtension method

The **RemoveExtension** method unloads an extension library.

Syntax

```
C++  
HRESULT RemoveExtension(  
    [in] ULONG64 Handle  
) ;
```

Parameters

Handle [in]

Specifies the handle of the extension library to unload. This is the handle returned by [AddExtension](#).

Return value

Return code	Description
S_OK	The method was successful.

This method can also return error values. See [Return Values](#) for more details.

Remarks

For more information on using extension libraries, see [Calling Extensions and Extension Functions](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugControl](#)
[IDebugControl2](#)
[IDebugControl3](#)
[AddExtension](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugControl::ReturnInput method

The **ReturnInput** method is used by **IDebugInputCallbacks** objects to send an input string to the engine following a request for input.

Syntax

```
C++  
HRESULT ReturnInput(  
    [in] PCSTR Buffer  
) ;
```

Parameters

Buffer [in]

Specifies the input string being sent to the engine.

Return value

Return code	Description
S_OK	The method was successful.
S_FALSE	The engine had already received the input it requested. The input string in <i>Buffer</i> was not received by the engine.

This method may also return error values. See [Return Values](#) for more details.

Remarks

For an overview of input in the debugger engine, see [Input and Output](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugControl::SetCodeLevel method

The **SetCodeLevel** method sets the current code level and is mainly used when stepping through code.

Syntax

```
C++  
HRESULT SetCodeLevel(  
    [in] ULONG Level  
) ;
```

Parameters

Level [in]

Specifies the current code level. *Level* can take one of the values in the following table.

Value	Description
DEBUG_LEVEL_SOURCE	<i>Source mode</i> . When stepping through code on the target, the size of a single step will be a line of source code.
DEBUG_LEVEL_ASSEMBLY	<i>Assembly mode</i> . When stepping through code on the target, the size of a single step will be a single processor instruction.

Return value

This method can also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

For more information about the code level, see [Using Source Files](#).

Requirements

Target platform	
Header	Dbgeng.h (include Dbgeng.h)

See also

[IDebugControl](#)
[IDebugControl2](#)
[IDebugControl3](#)
[GetCodeLevel](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugControl::SetEffectiveProcessorType method

The `SetEffectiveProcessorType` method sets the effective processor type of the processor of the computer that is running the target.

Syntax

```
C++  
HRESULT SetEffectiveProcessorType(  
    [in] ULONG Type  
) ;
```

Parameters

Type [in]

Specifies the type of the processor. For possible values, see the *Type* parameter in [GetActualProcessorType](#).

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

For more information, see [Target Information](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugControl](#)
[IDebugControl2](#)
[IDebugControl3](#)
[GetEffectiveProcessorType](#)

IDebugControl::SetEngineOptions method

The **SetEngineOptions** method changes the engine's options.

Syntax

```
C++
HRESULT SetEngineOptions(
    [in] ULONG Options
);
```

Parameters

Options [in]

Specifies the engine's new options. *Options* is a bit-set; it will replace the existing symbol options. For a description of the engine options, see [DEBUG_ENGOPT_XXX](#).

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

This method will set the engine's options to those specified in *Options*. Unlike [AddEngineOptions](#), any symbol options that are not listed in the *Options* bit-set will be removed.

After the engine options have been changed, the engine sends out notification to each client's event callback object by passing the DEBUG_CES_ENGINE_OPTIONS flag to the [IDebugEventCallbacks::ChangeEngineState](#) method.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

IDebugControl::SetEventFilterCommand method

The **SetEventFilterCommand** method sets a debugger command for the engine to execute when a specified event occurs.

Syntax

C++

```
HRESULT SetEventFilterCommand(
    [in] ULONG Index,
    [in] PCSTR Command
);
```

Parameters

Index [in]

Specifies the index of the event filter. *Index* can take any value between zero and one less than the total number of event filters returned by **GetNumberEventFilters** (inclusive). For more information about the index of the filters, see [Index and Exception Code](#).

Command [in]

Specifies the debugger command for the engine to execute when the event occurs.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

For more information about event filters, see [Event Filters](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugControl](#)

[GetEventFilterCommand](#)
[SetExceptionFilterSecondCommand](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugControl::SetExceptionFilterParameters method

The **SetExceptionFilterParameters** method changes the [break status](#) and [handling status](#) for some exception filters.

Syntax

C++

```
HRESULT SetExceptionFilterParameters(
    [in] ULONG Count,
    [in] PDEBUG_EXCEPTION_FILTER_PARAMETERS Params
);
```

Parameters

Count [in]

Specifies the number of exception filters to change the parameters for.

Params [in]

Specifies an array of exception filter parameters of type [DEBUG_EXCEPTION_FILTER_PARAMETERS](#). Only the **ExecutionOption**, **ContinueOption**, and **ExceptionCode** fields of these parameters are used. The **ExceptionCode** field is used to identify the *exception* whose exception filter will be changed. **ExecutionOption** specifies the new break status and **ContinueOption** specifies the new handling status.

If the value of the **ExceptionOption** field is DEBUG_FILTER_REMOVE and the exception filter is an arbitrary exception filter, the exception filter will be removed.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
E_OUTOFMEMORY	The maximum number of arbitrary exception filters has been exceeded.

Remarks

For each of the exception filter parameters in *Params*, if the exception, identified by exception code, already has a filter (specific or arbitrary), that filter will be changed. Otherwise, a new arbitrary exception filter will be added for the exception.

For more information about [event filters](#), see [Event Filters](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugControl](#)

IDebugControl::SetExceptionFilterSecondCommand method

The **SetExceptionFilterSecondCommand** method sets the command that will be executed by the [debugger engine](#) on the second chance of a specified *exception*.

Syntax

C++

```
HRESULT SetExceptionFilterSecondCommand(
    [in] ULONG Index,
    [in] PCSTR Command
);
```

Parameters

Index [in]

Specifies the index of the exception filter whose second-chance command will be set. *Index* must not refer to the specific event filters as these are not exception filters and only exception events get a second chance. If *Index* refers to the default exception filter, the second-chance command is set for all exceptions that do not have an exception filter.

Command [in]

Receives the second-chance command for the exception filter.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

For more information about [event filters](#), see [Event Filters](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugControl::SetExecutionStatus method

The **SetExecutionStatus** method requests that the debugger engine enter an executable state. Actual execution will not occur until the next time [WaitForEvent](#) is called.

Syntax

C++
HRESULT SetExecutionStatus(
 [in] ULONG Status
) ;

Parameters

Status [in]

Specifies the mode for the engine to use when executing. Possible values are those values in the table in [DEBUG STATUS XXX](#) whose precedence lies between DEBUG_STATUS_GO and DEBUG_STATUS_STEP_INTO.

Return value

This method may also return other error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
E_UNEXPECTED	Something prevented the execution of this method. Possible causes include: there is no current target, there is an outstanding request for input, or execution is not supported in the current target.
E_ACCESSDENIED	The target is already executing.
E_NOINTERFACE	No target can generate any more events.

Remarks

For more information, see [Target Information](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

IDebugControl::SetInterrupt method

The **SetInterrupt** method registers a user interrupt or breaks into the debugger.

Syntax

```
C++  
HRESULT SetInterrupt(  
    [in] ULONG Flags  
) ;
```

Parameters

Flags [in]

Specifies the type of interrupt to register. *Flags* can take one of the values listed in the following table.

Value	Description
DEBUG_INTERRUPT_ACTIVE	If the target is running, the engine will request a break into the debugger. This request might time out. For more information, see the "Remarks" section.
DEBUG_INTERRUPT_PASSIVE	Otherwise, when the target is suspended, the engine will register a user interrupt.
DEBUG_INTERRUPT_EXIT	The engine will register a user interrupt. If there is currently a WaitForEvent call running, the engine will force it to return. If there are any debugger commands causing execution in the target -- for example, g (Go) and p (Step) -- the engine will force them to complete. This does not force a break into the debugger, so the target might not be suspended. In which case, the WaitForEvent call will return E_PENDING.
	Otherwise, when the target is suspended, register a user interrupt.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

This method can be called at any time and from any thread. Once the interrupt has been registered, this method returns immediately.

If *Flags* is DEBUG_INTERRUPT_ACTIVE, and the interrupt times out, the engine will generate a synthetic exception event. This event will be sent to event callback's [IDebugEventCallbacks::Exception](#) method. The amount of time before the interrupt times out can be set using [SetInterruptTimeout](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugControl](#)
[IDebugControl2](#)
[IDebugControl3](#)
[GetInterrupt](#)
[GetInterruptTimeout](#)
[SetInterruptTimeout](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugControl::SetInterruptTimeout method

The **SetInterruptTimeout** method sets the number of seconds that the [debugger engine](#) should wait when requesting a break into the debugger.

Syntax

```
C++  
HRESULT SetInterruptTimeout(  
    [in] ULONG Seconds  
) ;
```

Parameters

Seconds [in]

Specifies the number of seconds that the engine should wait for the target when requesting a break into the debugger.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

The engine requests a break into the debugger when [SetInterrupt](#) is called with the DEBUG_INTERRUPT_ACTIVE flag.

If an interrupt times out, the engine will generate a synthetic exception event. This event will be sent to [event callback objects](#)'s [IDebugEventCallbacks::Exception](#) method.

Most targets do not support interrupt time-outs. Live user-mode debugging is one of the targets that does support them.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

IDebugControl::SetLogMask method

The **SetLogMask** method sets the output mask for the currently open log file.

Syntax

```
C++  
HRESULT SetLogMask(  
    [in] ULONG Mask  
) ;
```

Parameters

Mask [in]

Specifies the new output mask for the log file. See [DEBUG_OUTPUT_XXX](#) for details about this value.

Return value

This method can also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugControl::SetNotifyEventHandle method

The **SetNotifyEventHandle** method sets the event that will be signaled after the next *exception* in a target.

Syntax

```
C++  
HRESULT SetNotifyEventHandle(  
    [in] ULONG64 Handle  
) ;
```

Parameters

Handle [in]

Specifies the handle of the event to signal. If *Handle* is **NULL**, no event will be signaled.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

After setting the event to signal, and after the next exception occurs in a target, when the engine resumes execution in the target, the event will be signaled.

The event will only be signaled once. After it has been signaled, **GetNotifyEventHandle** will return **NULL**, unless this method is called to set another event to signal.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

IDebugControl::SetRadix method

The **SetRadix** method sets the default radix (number base) used by the [debugger engine](#) when it evaluates and displays MASM expressions, and when it displays symbol information.

Syntax

```
C++  
HRESULT SetRadix(  
    [in] ULONG Radix  
) ;
```

Parameters

Radix [in]

Specifies the new default radix. The following table contains the possible values for the radix.

Value	Description
8	Octal
10	Decimal
16	Hexadecimal

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

When the radix is changed, the engine notifies the event callbacks by passing the DEBUG_CES_RADIX flag to the [IDebugEventCallbacks::ChangeEngineState](#) callback method.

For more information about the default radix, see [Using Input and Output](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

IDebugControl::SetSpecificFilterArgument method

The **SetSpecificFilterArgument** method sets the value of filter argument for the specific filters that can have an argument.

Syntax

```
C++  
HRESULT SetSpecificFilterArgument(
```

```
[in] ULONG Index,
[in] PCSTR Argument
);
```

Parameters

Index [in]

Specifies the index of the specific filter whose argument will be set. *Index* must be the index of a specific filter that has an argument.

Argument [in]

Specifies the argument for the specific filter. The interpretation of this argument depends on the specific filter.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
E_INVALIDARG	<i>Index</i> does not refer to a specific filter that has an argument.

Remarks

For a list of specific filters that have argument and the interpretation of those arguments, see [Event Filters](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

© 2016 Microsoft. All rights reserved.

IDebugControl::SetSpecificFilterParameters method

The **SetSpecificFilterParameters** method changes the [break status](#) and [handling status](#) for some specific event filters.

Syntax

C++

```
HRESULT SetSpecificFilterParameters(
    [in] ULONG Start,
    [in] ULONG Count,
    [in] PDEBUG_SPECIFIC_FILTER_PARAMETERS Params
);
```

Parameters

Start [in]

Specifies the index of the first specific event filter whose parameters will be changed.

Count [in]

Specifies the number of specific event filters whose parameters will be changed.

Params [in]

Specifies an array of specific event filter parameters of type [DEBUG_SPECIFIC_FILTER_PARAMETERS](#). Only the **ExecutionOption** and **ContinueOption** members are used. **ExceptionOption** specifies the new break status and **ContinueOption** specifies the new handling status.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

For more information about [event filters](#), see [Event Filters](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

IDebugControl::SetSystemErrorControl method

The **SetSystemErrorControl** method sets the control values for handling system errors.

Syntax

C++
HRESULT SetSystemErrorControl(
 [in] ULONG OutputLevel,
 [in] ULONG BreakLevel
) ;

Parameters

OutputLevel [in]

Specifies the level at which system errors are printed to the engine's output. If the level of the system error is less than or equal to *OutputLevel*, the error is printed to the debugger console.

BreakLevel [in]

Specifies the level at which system errors break into the debugger. If the level of the system error is less than or equal to *BreakLevel*, the error breaks into the debugger.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

The level of a system error can take one of the following three values, listed from lowest to highest: SLE_ERROR, SLE_MINORERROR, and SLE_WARNING. These values are defined in Winuser.h.

When a system error occurs, the engine calls the [IDebugEventCallbacks::SystemError](#) method of the event callbacks. If the level is less than or equal to the *BreakLevel* parameter, the error will break into the debugger. If the level is greater than *BreakLevel*, the engine will proceed with execution in the target as indicated by the [IDebugEventCallbacks::SystemError](#) method calls. For more information about how the engine proceeds after an event, see [Monitoring Events](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugControl::SetTextMacro method

The **SetTextMacro** method sets the value of a fixed-name alias.

Syntax

```
C++
HRESULT SetTextMacro (
    [in] ULONG Slot,
    [in] PCSTR Macro
);
```

Parameters

Slot [in]

Specifies the number of the fixed-name alias. *Slot* can take the values 0, 1, ..., 9, that represent the fixed-name aliases **\$u0**, **\$u1**, ..., **\$u9**.

Macro [in]

Specifies the new value of the alias specified by *Slot*. The [debugger engine](#) makes a copy of this string.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

Before executing commands or evaluating expressions, the debugger engine will replace the alias specified by *Slot* with the value of the alias (specified by *Macro*).

For an overview of aliases used by the debugger engine, see [Using Aliases](#). For more information about using aliases with the debugger engine API, see [Interacting with the Engine](#).

IDebugControl::WaitForEvent method

The **WaitForEvent** method waits for an event that breaks into the debugger engine application.

Syntax

```
C++  
HRESULT WaitForEvent(  
    [in] ULONG Flags,  
    [in] ULONG Timeout  
) ;
```

Parameters

Flags [in]

Set to zero. There are currently no flags that can be used in this parameter.

Timeout [in]

Specifies how many milliseconds to wait before this method will return. If *Timeout* is INFINITE, this method will not return until an event that breaks into the debugger engine application occurs or an exit interrupt is issued. If the current session has a live kernel target, *Timeout* must be set to INFINITE.

Return value

This method may return other error values and the above error values may have additional meanings. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
S_FALSE	The time-out expired.
E_PENDING	An exit interrupt was issued. The target is not available.
E_UNEXPECTED	Either there is an outstanding request for input, or none of the targets could generate events.
E_FAIL	The engine is already waiting for an event.

Remarks

The method can be called only from the thread that started the debugger session.

When an event occurs, the [debugger engine](#) will process the event and call the event callbacks. If one of these callbacks indicates that the event should break into the debugger engine application (by returning DEBUG_STATUS_BREAK), this method will return; otherwise, it will continue waiting for an event. The event filters can also specify that an event should break into the debugger engine application. For more information about event filters, see [Controlling Exceptions and Events](#).

This method is not re-entrant. Once it has been called, it cannot be called again on any client until it has returned. In particular, it cannot be called from the event callbacks, including extensions and commands executed by the callbacks.

If none of the targets are capable of generating events -- for example, all the targets have exited -- this method will end the current session, discard the targets, and then return E_UNEXPECTED.

The constant INFINITE is defined in Winbase.h.

For more information about using **WaitForEvent** to control the execution flow of the debugger application and targets, see [Debugging Session and Execution Model](#). For details on the event callbacks, see [Monitoring Events](#).

IDebugControl2 interface

Members

The **IDebugControl2** interface inherits from [IDebugControl](#). **IDebugControl2** also has these types of members:

- [Methods](#)

Methods

The **IDebugControl2** interface has these methods.

Method	Description
GetCurrentSystemUpTime	Returns the number of seconds the current target's computer has been running since it was last started.
GetCurrentTimeDate	Returns the time of the current target.
GetDumpFormatFlags	Returns the flags that describe what information is available in a dump file target.
GetNumberTextReplacements	Returns the number of currently defined user-named and automatic aliases.
GetTextReplacement	Returns the value of a user-named alias or an automatic alias.
OutputTextReplacements	Prints all the currently defined user-named aliases to the debugger's output stream.
RemoveTextReplacements	Removes all user-named aliases.
SetTextReplacement	Sets the value of a user-named alias.

Requirements

Header Dbgeng.h (include Dbgeng.h)

IDebugControl2::GetCurrentSystemUpTime method

The **GetCurrentSystemUpTime** method returns the number of seconds the current target's computer has been running since it was last started.

Syntax

```
C++  
HRESULT GetCurrentSystemUpTime(  
    [out] PULONG UpTime  
) ;
```

Parameters

UpTime [out]

Receives the number of seconds the computer has been running, or **0** if the engine is unable to determine the running time.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The value of the variable <i>UpTime</i> is either the desired information or is 0 .

Remarks

For more information, see [Target Information](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugControl2](#)
[IDebugControl3](#)
[GetCurrentTimeDate](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugControl2::GetCurrentTimeDate method

The **GetCurrentTimeDate** method returns the time of the current target.

Syntax

```
C++  
HRESULT GetCurrentTimeDate(  
    [out] PULONG TimeDate  
) ;
```

Parameters

TimeDate [out]

Receives the time and date. This is the number of seconds since the beginning of 1970, or **0** if the current time could not be determined.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The value of the variable <i>TimeDate</i> is either the desired information or is 0 .

Remarks

For live debugging sessions, this will be the current time as reported by the target's computer. For static debugging sessions, such as crash dump files, this will be the time the crash dump file was created.

For more information, see [Target Information](#).

Requirements

Target platform

IDebugControl2::GetDumpFormatFlags method

The **GetDumpFormatFlags** method returns the flags that describe what information is available in a dump file target.

Syntax

```
C++  
HRESULT GetDumpFormatFlags(  
    [out] PULONG FormatFlags  
) ;
```

Parameters

FormatFlags [out]

Receives the flags that describe the information included in a dump file. Different dump files support different sets of format information. For example, see [DEBUG FORMAT XXX](#) for a description of the flags used for user-mode Minidump files.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

This method is only available when debugging crash dump files. If the crash dump file is in a default format or does not have variable formats, zero will be returned to *FormatFlags*.

Requirements

Target platform

IDebugControl2::GetNumberTextReplacements method

The **GetNumberTextReplacements** method returns the number of currently defined user-named and automatic aliases.

Syntax

C++

```
HRESULT GetNumberTextReplacements(
    [out] PULONG NumRepl
);
```

Parameters

NumRepl [out]

Receives the total number of user-named and automatic aliases.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

For an overview of aliases used by the [debugger engine](#), see [Using Aliases](#). For more information about using aliases with the debugger engine API, see [Interacting with the Engine](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugControl2::GetTextReplacement method

The **GetTextReplacement** method returns the value of a user-named alias or an automatic alias.

Syntax

C++

```
HRESULT GetTextReplacement(
    [in, optional] PCSTR SrcText,
    [in]           ULONG  Index,
    [out, optional] PSTR   SrcBuffer,
    [in]           ULONG  SrcBufferSize,
    [out, optional] PULONG SrcSize,
    [out, optional] PSTR   DstBuffer,
    [in]           ULONG  DstBufferSize,
    [out, optional] PULONG DstSize
);
```

Parameters

SrcText [in, optional]

Specifies the name of the alias. The engine first searches the user-named aliases for one with this name. Then, if no match is found, the automatic aliases are searched. If *SrcText* is **NULL**, *Index* is used to specify the alias.

Index [in]

Specifies the index of an alias. The indexes of the user-named aliases come before the indexes of the automatic aliases. *Index* is only used if *SrcText* is **NULL**. *Index* can be used along with [GetNumberTextReplacements](#) to iterate over all the user-named and automatic aliases.

SrcBuffer [out, optional]

Receives the name of the alias. This is the name specified in *SrcText*, if *SrcText* is not **NULL**. If *SrcBuffer* is **NULL**, this information is not returned.

SrcBufferSize [in]

Specifies the size, in characters, of the *SrcBuffer* buffer.

SrcSize [out, optional]

Receives the size, in characters, of the name of the alias. If *SrcSize* is **NULL**, this information is not returned.

DstBuffer [out, optional]

Receives the value of the alias specified by *SrcText* and *Index*. If *DstBuffer* is **NULL**, this information is not returned.

DstBufferSize [in]

Specifies the size, in characters, of the *DstBuffer* buffer.

DstSize [out, optional]

Receives the size, in characters, of the value of the alias. If *DstSize* is **NULL**, this information is not returned.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

Before executing commands or evaluating expressions, the debugger engine will replace the alias specified by *SrcBuffer* with the value of the alias (specified by *DstBuffer*).

For an overview of aliases used by the [debugger engine](#), see [Using Aliases](#). For more information about using aliases with the debugger engine API, see [Interacting with the Engine](#).

IDebugControl2::OutputTextReplacements method

The **OutputTextReplacements** method prints all the currently defined user-named aliases to the debugger's output stream.

Syntax

C++

```
HRESULT OutputTextReplacements(
    [in] ULONG OutputControl,
    [in] ULONG Flags
);
```

Parameters

OutputControl [in]

Specifies the output control to use when printing the aliases. For possible values, see [DEBUG_OUTCTL_XXX](#).

Flags [in]

Must be set to DEBUG_OUT_TEXT REPL_DEFAULT.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

For an overview of aliases used by the [debugger engine](#), see [Using Aliases](#). For more information about using aliases with the debugger engine API, see [Interacting with the Engine](#).

Requirements

IDebugControl2::RemoveTextReplacements method

The **RemoveTextReplacements** method removes all user-named aliases.

Syntax

C++

```
HRESULT RemoveTextReplacements();
```

Parameters

This method has no parameters.

Return value

Return code	Description
S_OK	The method was successful.

This method may also return error values. See [Return Values](#) for more details.

Remarks

For an overview of aliases used by the [debugger engine](#), see [Using Aliases](#). For more information about using aliases with the debugger engine API, see [Interacting with the Engine](#).

IDebugControl2::SetTextReplacement method

The **SetTextReplacement** method sets the value of a user-named alias.

Syntax

C++

```
HRESULT SetTextReplacement(
    [in]          PCSTR SrcText,
    [in, optional] PCSTR DstText
);
```

Parameters

SrcText [in]

Specifies the name of the user-named alias. The [debugger engine](#) makes a copy of this string. If *SrcText* is the same as the name of an automatic alias, the automatic alias is hidden by the new user-named alias.

DstText [in, optional]

Specifies the value of the user-named alias. The debugger engine makes a copy of this string. If *DstText* is **NULL**, the user-named alias is removed.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

Before executing commands or evaluating expressions, the debugger engine will replace the alias specified by *SrcText* with the value of the alias (specified by *DstText*).

If *SrcText* is an asterisk (*) and *DstText* is **NULL**, all user-named aliases are removed. This is the same behavior as the [RemoveTextReplacements](#) method.

When an alias is changed by this method, the event callbacks are notified by passing the DEBUG_CES_TEXT_REPLACEMENTS flag to the [IDebugEventCallbacks::ChangeEngineState](#) callback method.

For an overview of aliases used by the [debugger engine](#), see [Using Aliases](#). For more information about using aliases with the debugger engine API, see [Interacting with the Engine](#).

IDebugControl3 interface

Members

The **IDebugControl3** interface inherits from [IDebugControl2](#). **IDebugControl3** also has these types of members:

- [Methods](#)

Methods

The **IDebugControl3** interface has these methods.

Method	Description
AddAssemblyOptions	Turns on some of the assembly and disassembly options.
GetAssemblyOptions	Returns the assembly and disassembly options that affect how the debugger engine assembles and disassembles processor instructions for the target.
GetCurrentEventIndex	Returns the index of the current event within the current list of events for the current target, if such a list exists.
GetEventIndexDescription	Describes the specified event in a static list of events for the current target.
GetExpressionSyntax	Returns the current syntax that the engine is using for evaluating expressions.
GetExpressionSyntaxNames	Returns the full and abbreviated names of an expression syntax.
GetNumberEvents	Returns the number of events for the current target, if the number of events is fixed.
GetNumberExpressionSyntaxes	Returns the number of expression syntaxes that are supported by the engine.
RemoveAssemblyOptions	Turns off some of the assembly and disassembly options.
SetAssemblyOptions	Sets the assembly and disassembly options that affect how the debugger engine assembles and disassembles

SetAssemblyOptions
SetExpressionSyntax
SetExpressionSyntaxByName
SetNextEventIndex

processor instructions for the target.
Sets the syntax that the engine will use to evaluate expressions.
Sets the syntax that the engine will use to evaluate expressions.
Sets the next event for the current target by selecting the event from the static list of events for the target, if such a list exists.

IDebugControl3::AddAssemblyOptions method

The **AddAssemblyOptions** method turns on some of the assembly and disassembly options.

Syntax

```
C++  
HRESULT AddAssemblyOptions(  
    [in] ULONG Options  
) ;
```

Parameters

Options [in]

Specifies the assembly and disassembly options to turn on. *Options* is a bit-set that will be combined with the existing engine options using the bitwise OR operator. For a description of the options, see [DEBUG_ASMOPT_XXX](#).

Return value

Return code	Description
S_OK	The method was successful.

These methods can also return error values. See [Return Values](#) for more details.

Remarks

IDebugControl3::GetAssemblyOptions method

The **GetAssemblyOptions** method returns the assembly and disassembly options that affect how the [debugger engine](#) assembles and disassembles processor instructions for the target.

Syntax

```
C++  
HRESULT GetAssemblyOptions(  
    [out] PULONG Options  
) ;
```

Parameters

Options [out]

Receives a bit-set that contains the assembly and disassembly options. For a description of these options, see [DEBUG_ASMOPT_XXX](#).

Return value

This method can also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

For more information about using assembly with the debugger engine API, see [Assembling and Disassembling Instructions](#).

IDebugControl3::GetCurrentEventIndex method

The **GetCurrentEventIndex** method returns the index of the current event within the current list of events for the current target, if such a list exists.

Syntax

```
C++  
HRESULT GetCurrentEventIndex(  
    [out] PULONG Index  
) ;
```

Parameters

Index [out]

Receives the index of the current event in the target. The index will be a number between zero and one less than the number of events returned by [GetNumberEvents](#). The index of the first event is zero.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

Targets that do not have fixed sets of events will always return zero to *Index*.

Requirements

Target platform

IDebugControl3::GetEventIndexDescription method

The **GetEventIndexDescription** method describes the specified event in a static list of events for the current target.

Syntax

C++

```
HRESULT GetEventIndexDescription(
    [in]           ULONG   Index,
    [in]           ULONG   Which,
    [in, optional] PSTR    Buffer,
    [in]           ULONG   BufferSize,
    [out, optional] PULONG DescSize
);
```

Parameters

Index [in]

Specifies the index of the event whose description will be returned.

Which [in]

Specifies which piece of the event description to return. Currently only DEBUG_EINDEX_NAME is supported; this returns the name of the event.

Buffer [in, optional]

Receives the description of the event. If *Buffer* is **NULL**, this information is not returned.

BufferSize [in]

Specifies the size, in characters, of the *Buffer* buffer.

DescSize [out, optional]

Receives the size, in characters, of the description. If *DescSize* is **NULL**, this information is not returned.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

The amount of descriptive information available for a particular target varies depending on the type of the target.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugControl3::GetExpressionSyntax method

The **GetExpressionSyntax** method returns the current syntax that the engine is using for evaluating expressions.

Syntax

```
C++  
HRESULT GetExpressionSyntax(  
    [out] PULONG Flags  
) ;
```

Parameters

Flags [out]

Receives the expression syntax. It is set to one of the following values:

DEBUG_EXPR_MASM

Expressions will be evaluated according to MASM syntax. For details of this syntax, see [MASM Numbers and Operators](#).

DEBUG_EXPR_CPLUSPLUS

Expressions will be evaluated according to C++ syntax. For details of this syntax, see [C++ Numbers and Operators](#).

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugControl3](#)

IDebugControl3::GetExpressionSyntaxNames method

The **GetExpressionSyntaxNames** method returns the full and abbreviated names of an expression syntax.

Syntax

```
C++  
HRESULT GetExpressionSyntaxNames(  
    [in]          ULONG   Index,  
    [out, optional] PSTR    FullNameBuffer,  
    [in]          ULONG   FullNameBufferSize,  
    [out, optional] PULONG  FullNameSize,  
    [out, optional] PSTR    AbbrevNameBuffer,  
    [in]          ULONG   AbbrevNameBufferSize,  
    [out, optional] PULONG  AbbrevNameSize  
) ;
```

Parameters

Index [in]

Specifies the index of the expression syntax. *Index* should be between zero and the number of expression syntaxes returned by [GetNumberExpressionSyntaxes](#) minus one.

FullNameBuffer [out, optional]

Receives the full name of the expression syntax. If *FullNameBuffer* is **NULL**, this information is not returned.

FullNameBufferSize [in]

Specifies the size, in characters, of the buffer *FullNameBuffer*.

FullNameSize [out, optional]

Receives the size, in characters, of the full name of the expression syntax. If *FullNameSize* is **NULL**, this information is not returned.

AbbrevNameBuffer [out, optional]

Receives the abbreviated name of the expression syntax. If *AbbrevNameBuffer* is **NULL**, this information is not returned.

AbbrevNameBufferSize [in]

Specifies the size, in characters, of the buffer *AbbrevNameBufferSize*.

AbbrevNameSize [out, optional]

Receives the size, in characters, of the abbreviated name of the expression syntax. If *AbbrevNameSize* is **NULL**, this information is not returned.

Return value

This method can also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
S_FALSE	The method was successful. However, either <i>FullNameBufferSize</i> or <i>AbbrevNameBufferSize</i> was smaller than the size of the respective expression syntax name, and the name was truncated to fit inside the buffer.

Remarks

Currently, there are two expression syntaxes, their full names are "Microsoft Assembler expressions" and "C++ source expressions." The corresponding abbreviated expression syntaxes are "MASM" and "C++."

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugControl3::GetNumberEvents method

The **GetNumberEvents** method returns the number of [events](#) for the current target, if the number of events is fixed.

Syntax

```
C++  
HRESULT GetNumberEvents(  
    [out] PULONG Events  
) ;
```

Parameters

Events [out]

Receives the number of events stored in the target. If the target offers multiple events, *Events* will be set to the number of events available. Otherwise, *Events* will be set to one.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful, and <i>Events</i> contains the total number of events possible for the target.
S_FALSE	The method was successful, but <i>Events</i> contains only the total number of events possible at the current time. Targets that support variable execution might have different sets of events available at different points during the target's execution.

Remarks

Crash dump files contain a static list of events; each event represents a snapshot of the target at a particular point in time. If the current target is a crash dump file, this method sets *Events* to the number of stored events and returns **S_OK**.

Live targets generate events dynamically and do not necessarily have a known set of events. If the current target is a live target with unconstrained number of events, this method sets *Events* to the number of events currently available and returns **S_FALSE**.

For more information, see the topic [Event Information](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugControl3::GetNumberExpressionSyntaxes method

The **GetNumberExpressionSyntaxes** method returns the number of expression syntaxes that are supported by the engine.

Syntax

```
C++  
HRESULT GetNumberExpressionSyntaxes(  
    [out] PULONG Number  
) ;
```

Parameters

Number [out]

Receives the number of expression syntaxes.

Return value

This method can also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

IDebugControl3::RemoveAssemblyOptions method

The **RemoveAssemblyOptions** method turns off some of the assembly and disassembly options.

Syntax

C++
HRESULT RemoveAssemblyOptions(
 [in] ULONG Options
);

Parameters

Options [in]

Specifies the assembly and disassembly options to turn off. *Options* is a bit-set; the new value of the engine's options will equal the bitwise NOT of *Options* combined with the old value by using the bitwise AND operator (&).

). For a description of the assembly and disassembly options, see [DEBUG_ASMOPT_XXX](#).

Return value

Return code	Description
S_OK	The method was successful.

This method can also return error values. See [Return Values](#) for more details.

Remarks

For more information about using assembly with the debugger engine API, see [Assembling and Disassembling Instructions](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugControl3::SetAssemblyOptions method

The **SetAssemblyOptions** method sets the assembly and disassembly options that affect how the [debugger engine](#) assembles and disassembles processor instructions for the target.

Syntax

```
C++  
HRESULT SetAssemblyOptions(  
    [in] ULONG Options  
) ;
```

Parameters

Options [in]

Specifies the new assembly and disassembly options to be used by the [debugger engine](#). *Options* is a bit-set; it will replace the existing assembly and disassembly options. For possible values, see [DEBUG_ASMOPT_XXX](#). DEBUG_ASMOPT_DEFAULT can be used to set the default options.

Return value

This method can also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

For more information about using assembly with the debugger engine API, see [Assembling and Disassembling Instructions](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugControl3::SetExpressionSyntax method

The **SetExpressionSyntax** method sets the syntax that the engine will use to evaluate expressions.

Syntax

```
C++
HRESULT SetExpressionSyntax(
    [in] ULONG Flags
);
```

Parameters

Flags [in]

Specifies the syntax that the engine will use to evaluate expressions. It can be one of the following values:

DEBUG_EXPR_MASM

Expressions will be evaluated according to MASM syntax. For details of this syntax, see [MASM Numbers and Operators](#).

DEBUG_EXPR_CPLUSPLUS

Expressions will be evaluated according to C++ syntax. For details of this syntax, see [C++ Numbers and Operators](#).

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

The expression syntax is a global setting within the engine, so setting the expression syntax will affect all clients.

The expression syntax of the engine determines how the engine will interpret expressions passed to [Evaluate](#), [Execute](#), and any other method that evaluates an expression.

After the expression syntax has been changed, the engine sends out notification to the [IDebugEventCallbacks](#) registered with each client. It also passes the DEBUG_CES_EXPRESSION_SYNTAX flag to the [IDebugEventCallbacks::ChangeEngineState](#) method.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

IDebugControl3::SetExpressionSyntaxByName method

The **SetExpressionSyntaxByName** method sets the syntax that the engine will use to evaluate expressions.

Syntax

```
C++
HRESULT SetExpressionSyntaxByName (
    [in] PCSTR AbbrevName
);
```

Parameters

AbbrevName [in]

Specifies the abbreviated name of the syntax. It can be one of the following strings:

C++

Expressions will be evaluated according to C++ syntax. For details of this syntax, see [C++ Numbers and Operators](#).

MASM

Expressions will be evaluated according to MASM syntax. For details of this syntax, see [MASM Numbers and Operators](#).

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

The expression syntax is a global setting within the engine, so setting the expression syntax will affect all clients.

The expression syntax of the engine determines how the engine will interpret expressions passed to [Evaluate](#), [Execute](#), and any other method that evaluates an expression.

After the expression syntax has been changed, the engine sends out notification to the [IDebugEventCallbacks](#) callback object registered with each client. It also passes the DEBUG_CES_EXPRESSION_SYNTAX flag to the [IDebugEventCallbacks::ChangeEngineState](#) method.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

IDebugControl3::SetNextEventIndex method

The [SetNextEventIndex](#) method sets the next event for the current target by selecting the event from the static list of events for the target, if such a list exists.

Syntax

```
C++
HRESULT SetNextEventIndex(
    [in] ULONG Relation,
    [in] ULONG Value,
    [out] PULONG NextIndex
);
```

Parameters

Relation [in]

Specifies how to interpret *Value* when setting the index of the next event. Possible values are: DEBUG_EINDEX_FROM_START, DEBUG_EINDEX_FROM_END, and DEBUG_EINDEX_FROM_CURRENT.

Value [in]

Specifies the index of the next event relative to the first, last, or current event. The interpretation of *Value* depends on the value of *Relation*, as follows.

Value of <i>Relation</i>	Next Event Index
DEBUG_EINDEX_FROM_START	<i>Value</i> .
DEBUG_EINDEX_FROM_END	Number of events minus <i>Value</i> .
DEBUG_EINDEX_FROM_CURRENT	The current event index plus <i>Value</i> .

The resulting index must be greater than zero and one less than the number of events returned by [GetNumberOfEvents](#).

NextIndex [out]

Receives the index of the next event. If *NextIndex* is **NULL**, this information is not returned.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

If the specified event is the same as the current event, this method does nothing. Otherwise, this method sets the execution status of the target to DEBUG_STATUS_GO (and notifies the event callbacks). When [WaitForEvent](#) is called, the engine will generate the specified event for the event callbacks and set it as the current event.

This method is only useful if the target offers a list of events.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

IDebugControl4 interface

Members

The IDebugControl4 interface inherits from [IDebugControl3](#). IDebugControl4 also has these types of members:

- [Methods](#)

Methods

The IDebugControl4 interface has these methods.

Method	Description
AddBreakpoint2	Creates a new breakpoint for the current target.
AddExtensionWide	Loads an extension library into the debugger engine.
AssembleWide	Assembles a single processor instruction.
CallExtensionWide	Calls a debugger extension.
ControlledOutputVaListWide	Formats a string and sends the result to output callbacks that were registered with some of the engine's clients.
ControlledOutputWide	Formats a string and sends the result to output callbacks that were registered with some of the engine's clients.
DisassembleWide	Disassembles a processor instruction in the target's memory.
EvaluateWide	Evaluates an expression, returning the result.
ExecuteCommandFileWide	Opens the specified file and executes the debugger commands that are contained within.
ExecuteWide	Executes the specified debugger commands.
GetBreakpointById2	Returns the breakpoint with the specified breakpoint ID.
GetBreakpointByIndex2	Returns the breakpoint located at the specified index.
GetContextStackTrace	Returns the frames at the top of the call stack, starting with an arbitrary register context and returning the reconstructed register context for each stack frame.
GetEventFilterCommandWide	Returns the debugger command that the engine will execute when a specified event occurs.
GetEventFilterTextWide	Returns a short description of an event for a specific filter.
GetEventIndexDescriptionWide	Describes the specified event in a static list of events for the current target.
GetExceptionFilterSecondCommandWide	Returns the command that will be executed by the debugger engine upon the second chance of a specified exception.
GetExpressionSyntaxNamesWide	Returns the full and abbreviated names of an expression syntax.
GetExtensionByPathWide	Returns the handle for an already loaded extension library.
GetExtensionFunctionWide	Returns a pointer to an extension function from an extension library.

GetLastEventInformationWide	Returns information about the last event that occurred in a target.
GetLogFile2	Returns the name of the currently open log file.
GetLogFile2Wide	Returns the name of the currently open log file.
GetLogFileWide	Returns the name of the currently open log file.
GetManagedStatus	
GetManagedStatusWide	
GetProcessorTypeNamesWide	Returns the full name and abbreviated name of the specified processor type.
GetPromptTextWide	Returns the standard prompt text that will be prepended to the formatted output specified in the OutputPrompt and OutputPromptVaList methods.
GetSpecificFilterArgumentWide	Returns the value of filter argument for the specific filters that have an argument.
GetStoredEventInformation	Retrieves information about an event of interest available in the current target.
GetSystemVersionString	Returns a string that describes the target's operating system version. (ANSI version)
GetSystemVersionStringWide	Returns a string that describes the target's operating system version. (Unicode version)
GetSystemVersionValues	Returns version number information for the current target.
GetTextMacroWide	Returns the value of a fixed-name alias.
GetTextReplacementWide	Returns the value of a user-named alias or an automatic alias.
InputWide	Requests an input string from the debugger engine.
OpenLogFile2	Opens a log file that will receive output from the client objects .
OpenLogFile2Wide	Opens a log file that will receive output from the client objects .
OpenLogFileWide	Opens a log file that will receive output from the client objects.
OutputContextStackTrace	Prints the call stack specified by an array of stack frames and corresponding register contexts.
OutputPromptVaListWide	Formats and sends a user prompt to the output callback objects.
OutputPromptWide	Formats and sends a user prompt to the output callback objects.
OutputVaListWide	Formats a string and sends the result to the output callbacks that are registered with the engine's clients.
OutputWide	Formats a string and send the result to output callbacks that have been registered with the engine's clients.
RemoveBreakpoint2	Removes a breakpoint.
ResetManagedStatus	
ReturnInputWide	This method is used by IDebugInputCallbacks objects to send an input string to the engine following a request for input.
SetEventFilterCommandWide	Sets a debugger command for the engine to execute when a specified event occurs.
SetExceptionFilterSecondCommandWide	Sets the command that will be executed by the debugger engine on the second chance of a specified exception.
SetExpressionSyntaxByNameWide	Sets the syntax that the engine will use to evaluate expressions.
SetSpecificFilterArgumentWide	Sets the value of filter argument for the specific filters that can have an argument.
SetTextMacroWide	Sets the value of a fixed-name alias.
SetTextReplacementWide	Sets the value of a user-named alias.

Requirements

Header Dbgeng.h (include Dbgeng.h)

© 2016 Microsoft. All rights reserved.

IDebugControl4::AddBreakpoint2 method

The **AddBreakpoint2** method creates a new breakpoint for the current target.

Syntax

C++

```
HRESULT AddBreakpoint2(
    [in]    ULONG          Type,
    [in]    ULONG          DesiredId,
    [out]   IDebugBreakpoint **Bp
);
```

Parameters

Type [in]

Specifies the breakpoint type of the new breakpoint. This can be either of the following values:

Value	Description
DEBUG_BREAKPOINT_CODE	software breakpoint
DEBUG_BREAKPOINT_DATA	processor breakpoint

DesiredId [in]

Specifies the desired ID of the new breakpoint. If it is DEBUG_ANY_ID, the engine will pick an unused ID.

Bp [out]

Receives an interface pointer to the new breakpoint.

Return value

Return code	Description
S_OK	The method was successful.
E_INVALIDARG	The breakpoint couldn't be created with the desired ID or the value of <i>Type</i> was not recognized.

This method may also return other error values. See [Return Values](#) for more details.

Remarks

If *DesiredId* is not DEBUG_ANY_ID and another breakpoint already uses the ID *DesiredId*, these methods will fail.

Breakpoints are created empty and disabled. See [Using Breakpoints](#) for details on configuring and enabling the breakpoint.

The client is saved as the adder of the new breakpoint. See [GetAdder](#).

Note Even though [IDebugBreakpoint](#) extends the COM interface **IUnknown**, the lifetime of the breakpoint is not controlled using the **IUnknown** interface. Instead, the breakpoint is deleted after [RemoveBreakpoint](#) is called.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugControl4](#)

[Breakpoints](#)

[Using Breakpoints](#)

[IDebugBreakpoint](#)

[RemoveBreakpoint](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugControl4::AddExtensionWide method

The **AddExtensionWide** method loads an extension library into the [debugger engine](#).

Syntax

```
C++
HRESULT AddExtensionWide(
    [in] PCSTR Path,
    [in] ULONG Flags,
    [out] PULONG64 Handle
);
```

Parameters

Path [in]

Specifies the fully qualified path and file name of the extension library to load.

Flags [in]

Set to zero.

Handle [out]

Receives the handle of the loaded extension library.

Return value

Return code	Description
S_OK	The method was successful.

This method can also return error values. See [Return Values](#) for more details.

Remarks

If the extension library has already been loaded, the handle to already loaded library is returned. The extension library is not loaded again.

The extension library is loaded into the host engine and *Path* contains a path and file name for this instance of the debugger engine.

For more information on using extension libraries, see [Calling Extensions and Extension Functions](#).

Requirements**Target platform**

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugControl4](#)
[RemoveExtension](#)
[GetExtensionByPath](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugControl4::AssembleWide method

The **AssembleWide** method assembles a single processor instruction. The assembled instruction is placed in the target's memory.

Syntax

```
C++
HRESULT AssembleWide(
    [in]  ULONG64  Offset,
    [in]  PCWSTR   Instr,
    [out] PULONG64 EndOffset
);
```

Parameters*Offset* [in]

Specifies the location in the target's memory to place the assembled instruction.

Instr [in]

Specifies the instruction to assemble. The instruction is assembled according to the target's effective processor type (returned by [SetEffectiveProcessorType](#)).

EndOffset [out]

Receives the location in the target's memory immediately following the assembled instruction. *EndOffset* can be used when assembling multiple instructions.

Return value

Return code	Description
S_OK	The method was successful.

This method can also return error values. See [Return Values](#) for more details.

Remarks

The assembly language depends on the effective processor type of the target machine. For information about the assembly language, see the processor documentation.

Note The [Assemble](#) and [AssembleWide](#) methods are not supported on some architectures, and on some other architectures not all instructions are supported.

The assembly language options--returned by [GetAssemblyOptions](#)--affect the operation of this method.

For an overview of using assembly in debugger applications, see [Debugging in Assembly Mode](#). For more information about using assembly with the [debugger engine API](#), see [Assembling and Disassembling Instructions](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugControl4](#)
[Disassemble](#)
[GetAssemblyOptions](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugControl4::CallExtensionWide method

The **CallExtensionWide** method calls a debugger extension.

Syntax

```
C++
HRESULT CallExtensionWide(
    [in]          ULONG64 Handle,
    [in]          PCSTR    Function,
    [in, optional] PCSTR    Arguments
);
```

Parameters

Handle [in]

Specifies the handle of the extension library that contains the extension to call. If *Handle* is zero, the engine will walk the extension library chain searching for the extension.

Function [in]

Specifies the name of the extension to call.

Arguments [in, optional]

Specifies the arguments to pass to the extension. *Arguments* is a string that will be parsed by the extension, just like the extension will parse arguments passed to it when called as an extension command.

Return value

Return code	Description
S_OK	The method was successful.

This method can also return error values. See [Return Values](#) for more details.

Remarks

If *Handle* is zero, the engine searches each extension library until it finds one that contains the extension; the extension will then be called. If the extension returns DEBUG_EXTENSION_CONTINUE_SEARCH, the search will continue.

For more information on using extension libraries, see [Calling Extensions and Extension Functions](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugControl4](#)
[AddExtension](#)
[GetExtensionByPath](#)
[GetExtensionFunction](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugControl4::ControlledOutputWide method

The **ControlledOutputWide** method formats a string and sends the result to [output callbacks](#) that were registered with some of the engine's clients.

Syntax

```
C++
HRESULT ControlledOutputWide(
    [in] ULONG OutputControl,
    [in] ULONG Mask,
    [in] PCWSTR Format,
    ...
);
```

Parameters

OutputControl [in]

Specifies an output control that determines which of the clients' output callbacks will receive the output. For possible values, see [DEBUG_OUTCTL_XXX](#). For more information about output, see [Input and Output](#).

Mask [in]

Specifies the output-type bit field. See [DEBUG_OUTPUT_XXX](#) for possible values.

Format [in]

Specifies the format string, as in **printf**. Typically, conversion characters work exactly as they do in C. For the floating-point conversion characters, the 64-bit argument is interpreted as a 32-bit floating-point number unless the **I** modifier is used.

The **%p** conversion character is supported, but it represents a pointer in a target's address space. It might not have any modifiers and it uses the debugger's internal address formatting. The following additional conversion characters are supported.

Character	Argument type	Argument	Text printed
%p	ULONG64	Pointer in an address space.	The value of the pointer.
%N	DWORD_PTR (32 or 64 bits, depending on the host's architecture)	Pointer in the host's virtual address space.	The value of the pointer. (This is equivalent to the standard C %p character.)
%I	ULONG64	Any 64-bit value.	The specified value. If this is greater than 0xFFFFFFFF, it is printed as a 64-bit value; otherwise, it is printed as a 32-bit value.
%ma	ULONG64	Address of a NULL-terminated ASCII string in the process's virtual address space.	The specified string.
%mu	ULONG64	Address of a NULL-terminated Unicode string in the process's virtual address space.	The specified string.
%msa	ULONG64	Address of an ANSI_STRING structure in the process's virtual address space.	The specified string.
%msu	ULONG64	Address of a UNICODE_STRING structure in the process's virtual address space.	The specified string.
%y	ULONG64	Address in the process's virtual address space of an item with symbol information.	String that contains the name of the specified symbol (and displacement, if any).
%ly	ULONG64	Address in the process's virtual address space of an item with symbol information.	String that contains the name of the specified symbol (and displacement, if any), as well as any available source line information.

The **%Y** format specifier can be used to support the Debugger Markup Language (DML). For more information, see [Customizing Debugger Output Using DML](#).

The following table summarizes the use of the **%Y** format specifier.

Character	Argument type	Argument	Text printed
%Y{t}	String	Text	Quoted string. Will convert text to DML if the output format (first arg) is DML.
%Y{T}	String	Text	Quoted string. Will always convert text to DML regardless of the output format.
%Y{s}	String	Text	Unquoted string. Will convert text to DML if the output format (first arg) is DML.
%Y{S}	String	Text	Unquoted string. Will always convert text to DML regardless of the output format.
%Y{as}	ULONG64	Debugger formatted pointer	Adds either an empty string or 9 characters of spacing for padding the high 32-bit portion of debugger formatted pointer fields. The extra space outputs 9 spaces which includes the upper 8 zeros plus the ` character.
%Y{ps}	ULONG64	Debugger formatted pointer	Adds either an empty string or 8 characters of spacing for padding the high 32-bit portion of debugger formatted pointer fields.
%Y{l}	ULONG64	Debugger formatted pointer	Address as source line information.

This code snippet illustrates the use of the %Y format specifier.

```
HRESULT CALLBACK testout(_In_ PDEBUG_CLIENT pClient, _In_ PCWSTR /*pwszArgs*/)
{
    HRESULT hr = S_OK;

    ComPtr spControl;
    IfFailedReturn(pClient->QueryInterface(IID_PPV_ARGS(&spControl)));

    spControl->ControlledOutputWide(DEBUG_OUTCTL_DML, DEBUG_OUTPUT_NORMAL, L"DML/NORMAL Y{t}: %Y{t}\n", L"Hello <World>");
    spControl->ControlledOutputWide(DEBUG_OUTCTL_DML, DEBUG_OUTPUT_NORMAL, L"DML/NORMAL Y{T}: %Y{T}\n", L"Hello <World>");
    spControl->ControlledOutputWide(DEBUG_OUTCTL_DML, DEBUG_OUTPUT_NORMAL, L"DML/NORMAL Y{s}: %Y{s}\n", L"Hello <World>");
    spControl->ControlledOutputWide(DEBUG_OUTCTL_DML, DEBUG_OUTPUT_NORMAL, L"DML/NORMAL Y{S}: %Y{S}\n", L"Hello <World>");

    spControl->ControlledOutputWide(0, DEBUG_OUTPUT_NORMAL, L"TEXT/NORMAL Y{t}: %Y{t}\n", L"Hello <World>");  

    spControl->ControlledOutputWide(0, DEBUG_OUTPUT_NORMAL, L"TEXT/NORMAL Y{T}: %Y{T}\n", L"Hello <World>");  

    spControl->ControlledOutputWide(0, DEBUG_OUTPUT_NORMAL, L"TEXT/NORMAL Y{s}: %Y{s}\n", L"Hello <World>");  

    spControl->ControlledOutputWide(0, DEBUG_OUTPUT_NORMAL, L"TEXT/NORMAL Y{S}: %Y{S}\n", L"Hello <World>");

    spControl->ControlledOutputWide(DEBUG_OUTCTL_DML, DEBUG_OUTPUT_NORMAL, L"DML/NORMAL Y{a}: %Y{a}\n", (ULONG64)0x00007ffa7da163c0);
    spControl->ControlledOutputWide(DEBUG_OUTCTL_DML, DEBUG_OUTPUT_NORMAL, L"DML/NORMAL Y{as} 64bit : '%Y{as}'\n", (ULONG64)0x00007ff  

    spControl->ControlledOutputWide(DEBUG_OUTCTL_DML, DEBUG_OUTPUT_NORMAL, L"DML/NORMAL Y{as} 32value : '%Y{as}'\n", (ULONG64)0x1);

    spControl->ControlledOutputWide(DEBUG_OUTCTL_DML, DEBUG_OUTPUT_NORMAL, L"DML/NORMAL Y{ps} 64bit : '%Y{ps}'\n", (ULONG64)0x00007ff  

    spControl->ControlledOutputWide(DEBUG_OUTCTL_DML, DEBUG_OUTPUT_NORMAL, L"DML/NORMAL Y{ps} 32value : '%Y{ps}'\n", (ULONG64)0x1);

    spControl->ControlledOutputWide(DEBUG_OUTCTL_DML, DEBUG_OUTPUT_NORMAL, L"DML/NORMAL Y{l}: %Y{l}\n", (ULONG64)0x00007ffa7da163c0);

    return hr;
}
```

This sample code would generate the following output.

```
0:004> !testout
DML/NORMAL Y{t}: "Hello <World>"  

DML/NORMAL Y{T}: "Hello <World>"  

DML/NORMAL Y{s}: Hello <World>  

DML/NORMAL Y{S}: Hello <World>  

TEXT/NORMAL Y{t}: "Hello <World>"  

TEXT/NORMAL Y{T}: "&quot;Hello &lt;World&gt;&quot;"  

TEXT/NORMAL Y{s}: Hello <World>  

TEXT/NORMAL Y{S}: Hello &lt;World&gt;  

DML/NORMAL Y{a}: 00007ffa7da163c0  

DML/NORMAL Y{as} 64bit : ' '  

DML/NORMAL Y{as} 32value : ' '  

DML/NORMAL Y{ps} 64bit : ' '  

DML/NORMAL Y{ps} 32value : ' '  

DML/NORMAL Y{l}: [d:\th\minkernel\kernelbase\debug.c @ 443]  

...  

```

Specifies additional parameters that represent values to be inserted into the output during formatting.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

When generating very large output strings, it is possible to reach the limits of the debugger engine or of the operating system. For example, some versions of the debugger engine have a 16K character limit for a single output. If you find that very large output is getting truncated, you might need to split your output into multiple requests.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

IDebugControl4::ControlledOutputVaListWide method

The **ControlledOutputVaListWide** method formats a string and sends the result to [output callbacks](#) that were registered with some of the engine's clients.

Syntax

```
C++
HRESULT ControlledOutputVaListWide(
    [in] ULONG   OutputControl,
    [in] ULONG   Mask,
    [in] PCWSTR  Format,
    [in] va_list Args
);
```

Parameters

OutputControl [in]

Specifies an output control that determines which client's output callbacks will receive the output. For possible values, see [DEBUG_OUTCTL_XXX](#). For more information about output, see [Input and Output](#).

Mask [in]

Specifies the output-type bit field. See [DEBUG_OUTPUT_XXX](#) for possible values.

Format [in]

Specifies the format string, as in **printf**. Typically, conversion characters work exactly as they do in C. For the floating-point conversion characters, the 64-bit argument is interpreted as a 32-bit floating-point number unless the **I** modifier is used.

The **%p** conversion character is supported, but it represents a pointer in a target's address space. It might not have any modifiers, and it uses the debugger's internal address formatting. The following additional conversion characters are supported.

Character	Argument type	Argument	Text printed
%p	ULONG64	Pointer in an address space.	The value of the pointer.
%N	DWORD_PTR (32 or 64 bits, depending on the host's architecture)	Pointer in the host's virtual address space.	The value of the pointer. (This is equivalent to the standard C %p character.)
%I	ULONG64	Any 64-bit value.	The specified value. If this is greater than 0xFFFFFFFF, it is printed as a 64-bit value; otherwise, it is printed as a 32-bit value.
%ma	ULONG64	Address of a NULL-terminated ASCII string in the process's virtual address space.	The specified string.
%mu	ULONG64	Address of a NULL-terminated Unicode string in the process's virtual address space.	The specified string.
%msa	ULONG64	Address of an ANSI_STRING structure in the process's virtual address space.	The specified string.
%msu	ULONG64	Address of a UNICODE_STRING structure in the process's virtual address space.	The specified string.
%oy	ULONG64	Address in the process's virtual address space of an item with symbol information.	String that contains the name of the specified symbol (and displacement, if any).
%oly	ULONG64	Address in the process's virtual address space of an item with symbol information.	String that contains the name of the specified symbol (and displacement, if any), as well as any available source line information.

The **%Y** format specifier can be used to support the Debugger Markup Language (DML). For more information, see [Customizing Debugger Output Using DML](#).

The following table summarizes the use of the **%Y** format specifier.

Character	Argument type	Argument	Text printed
-----------	---------------	----------	--------------

%Y{t}	String	Text	Quoted string. Will convert text to DML if the output format (first arg) is DML.
%Y{T}	String	Text	Quoted string. Will always convert text to DML regardless of the output format.
%Y{s}	String	Text	Unquoted string. Will convert text to DML if the output format (first arg) is DML.
%Y{S}	String	Text	Unquoted string. Will always convert text to DML regardless of the output format.
%Y{as}	ULONG64	Debugger formatted pointer	Adds either an empty string or 9 characters of spacing for padding the high 32-bit portion of debugger formatted pointer fields. The extra space outputs 9 spaces which includes the upper 8 zeros plus the ` character.
%Y{ps}	ULONG64	Debugger formatted pointer	Adds either an empty string or 8 characters of spacing for padding the high 32-bit portion of debugger formatted pointer fields.
%Y{l}	ULONG64	Debugger formatted pointer	Address as source line information.

This code snippet illustrates the use of the %Y format specifier.

```
HRESULT CALLBACK testout(_In_ PDEBUG_CLIENT pClient, _In_ PCWSTR /*pwszArgs*/)
{
    HRESULT hr = S_OK;

    ComPtr<IDebugControl4> spControl;
    IfFailedReturn(pClient->QueryInterface(IID_PPV_ARGS(&spControl)));

    spControl->ControlledOutputWide(DEBUG_OUTCTL_DML, DEBUG_OUTPUT_NORMAL, L"DML/NORMAL Y(t): %Y{t}\n", L"Hello <World>");
    spControl->ControlledOutputWide(DEBUG_OUTCTL_DML, DEBUG_OUTPUT_NORMAL, L"DML/NORMAL Y(T): %Y{T}\n", L"Hello <World>");
    spControl->ControlledOutputWide(DEBUG_OUTCTL_DML, DEBUG_OUTPUT_NORMAL, L"DML/NORMAL Y(s): %Y{s}\n", L"Hello <World>");
    spControl->ControlledOutputWide(DEBUG_OUTCTL_DML, DEBUG_OUTPUT_NORMAL, L"DML/NORMAL Y(S): %Y{S}\n", L"Hello <World>");

    spControl->ControlledOutputWide(0, DEBUG_OUTPUT_NORMAL, L"TEXT/NORMAL Y(t): %Y{t}\n", L"Hello <World>");
    spControl->ControlledOutputWide(0, DEBUG_OUTPUT_NORMAL, L"TEXT/NORMAL Y(T): %Y{T}\n", L"Hello <World>");
    spControl->ControlledOutputWide(0, DEBUG_OUTPUT_NORMAL, L"TEXT/NORMAL Y(s): %Y{s}\n", L"Hello <World>");
    spControl->ControlledOutputWide(0, DEBUG_OUTPUT_NORMAL, L"TEXT/NORMAL Y(S): %Y{S}\n", L"Hello <World>");

    spControl->ControlledOutputWide(DEBUG_OUTCTL_DML, DEBUG_OUTPUT_NORMAL, L"DML/NORMAL Y(a): %Y{a}\n", (ULONG64)0x00007ffa7da163c0);
    spControl->ControlledOutputWide(DEBUG_OUTCTL_DML, DEBUG_OUTPUT_NORMAL, L"DML/NORMAL Y(as) 64bit : '%Y{as}'\n", (ULONG64)0x00007ff
    spControl->ControlledOutputWide(DEBUG_OUTCTL_DML, DEBUG_OUTPUT_NORMAL, L"DML/NORMAL Y(as) 32value : '%Y{as}'\n", (ULONG64)0x1);

    spControl->ControlledOutputWide(DEBUG_OUTCTL_DML, DEBUG_OUTPUT_NORMAL, L"DML/NORMAL Y(ps) 64bit : '%Y{ps}'\n", (ULONG64)0x00007ff
    spControl->ControlledOutputWide(DEBUG_OUTCTL_DML, DEBUG_OUTPUT_NORMAL, L"DML/NORMAL Y(ps) 32value : '%Y{ps}'\n", (ULONG64)0x1);

    spControl->ControlledOutputWide(DEBUG_OUTCTL_DML, DEBUG_OUTPUT_NORMAL, L"DML/NORMAL Y(l): %Y{l}\n", (ULONG64)0x00007ffa7da163c0);

    return hr;
}
```

This sample code would generate the following output.

```
0:004> !testout
DML/NORMAL Y(t): "Hello <World>"
DML/NORMAL Y(T): "Hello <World>"
DML/NORMAL Y(s): Hello <World>
DML/NORMAL Y(S): Hello <World>
TEXT/NORMAL Y(t): "Hello <World>""
TEXT/NORMAL Y(T): "&quot;Hello &lt;World&>&quot;
TEXT/NORMAL Y(s): Hello <World>
TEXT/NORMAL Y(S): Hello &lt;World&>;
DML/NORMAL Y(a): 00007ffa`7da163c0
DML/NORMAL Y(as) 64bit : ' '
DML/NORMAL Y(as) 32value : ' '
DML/NORMAL Y(ps) 64bit : ' '
DML/NORMAL Y(ps) 32value : ' '
DML/NORMAL Y(l): [d:\th\minkernel\kernelbase\debug.c @ 443]
```

Args [in]

Specifies additional parameters that represent values to be inserted into the output during formatting. *Args* must be initialized using **va_start**. This method does not call **va_end**.

Return value

Return code	Description
S_OK	The method was successful.

This method may also return error values. See [Return Values](#) for more details.

Remarks

When generating very large output strings, it is possible to reach the limits of the debugger engine or of the operating system. For example, some versions of the debugger engine have a 16K character limit for a single output. If you find that very large output is getting truncated, you might need to split your output into multiple requests.

The macros **va_list**, **va_start**, and **va_end** are defined in Stdarg.h.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h or Stdarg.h)

See also[IDebugControl4](#)[ControlledOutput](#)[dprintf](#)[OutputVaList](#)[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugControl4::DisassembleWide method

The **DisassembleWide** method disassembles a processor instruction in the target's memory.

Syntax

```
C++  
HRESULT DisassembleWide(  
    [in]          ULONG64  Offset,  
    [in]          ULONG    Flags,  
    [out, optional] PWSTR   Buffer,  
    [in]          ULONG    BufferSize,  
    [out, optional] PULONG   DisassemblySize,  
    [out]         PULONG64 EndOffset  
) ;
```

Parameters

Offset [in]

Specifies the location in the target's memory of the instruction to disassemble.

Flags [in]

Specifies the bit-flags that affect the behavior of this method. Currently the only flag that can be set is DEBUG_DISASM_EFFECTIVE_ADDRESS; when set, the engine will compute the effective address from the current register information and display it.

Buffer [out, optional]

Receives the disassembled instruction. If *Buffer* is **NULL**, this information is not returned.

BufferSize [in]

Specifies the size, in characters, of the *Buffer* buffer.

DisassemblySize [out, optional]

Receives the size, in characters, of the disassembled instruction. If *DisassemblySize* is **NULL**, this information is not returned.

EndOffset [out]

Receives the location in the target's memory of the instruction following the disassembled instruction.

Return value

This method can also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
S_FALSE	The method was successful. However, <i>Buffer</i> was too small to hold the disassembled instruction and the instruction was truncated to fit.

Remarks

The assembly language depends on the effective processor type of the target system. For information about the assembly language, see the processor documentation.

The disassembly options--returned by [GetAssemblyOptions](#)--affect the operation of this method.

For an overview of using assembly in debugger applications, see [Debugging in Assembly Mode](#). For more information about using assembly with the debugger engine API,

see [Assembling and Disassembling Instructions](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

© 2016 Microsoft. All rights reserved.

IDebugControl4::EvaluateWide method

The **EvaluateWide** method evaluates an expression, returning the result.

Syntax

```
C++  
HRESULT EvaluateWide(  
    [in]          PCWSTR      Expression,  
    [in]          ULONG        DesiredType,  
    [out]         PDEBUG_VALUE Value,  
    [out, optional] PULONG     RemainderIndex  
) ;
```

Parameters

Expression [in]

Specifies the expression to be evaluated.

DesiredType [in]

Specifies the desired return type. Possible values are described in [DEBUG_VALUE](#); with the addition of DEBUG_VALUE_INVALID, which indicates that the return type should be the expression's natural type.

Value [out]

Receives the value of the expression.

RemainderIndex [out, optional]

Receives the index of the first character of the expression not used in the evaluation. If *RemainderIndex* is NULL, this information isn't returned.

Return value

This method may also return other error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
E_FAIL	An error occurred while evaluating the expression. For example, there was a syntax error, an undefined variable, or a division by zero exception.

Remarks

Expressions are evaluated by the current *expression evaluator*. The engine contains multiple expression evaluators; each supports a different syntax. The current expression evaluator can be chosen by using [SetExpressionSyntax](#).

For details of the available expression evaluators and their syntaxes, see [Numerical Expression Syntax](#).

If an error occurs while evaluating the expression, returning E_FAIL, the *RemainderIndex* variable can be used to determine approximately where in the expression the error occurred.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

IDebugControl4::ExecuteCommandFileWide method

The **ExecuteCommandFileWide** method opens the specified file and executes the debugger commands that are contained within.

Syntax

C++

```
HRESULT ExecuteCommandFileWide(
    [in] ULONG OutputControl,
    [in] PCWSTR Commandfile,
    [in] ULONG Flags
);
```

Parameters

OutputControl [in]

Specifies where to send the output of the command. For possible values, see [DEBUG_OUTCTL_XXX](#). For more information about output, see [Input and Output](#).

CommandFile [in]

Specifies the name of the file that contains the commands to execute. This file is opened for reading and its contents are interpreted as if they had been typed into the debugger console.

Flags [in]

Specifies execution options for the command. The default options are to log the command but not to send it to the output. For details about the values that *Flags* can take, see [Execute](#).

Return value

This method might also return error values, including error values caused by a failure to open the specified file. For more information, see [Return Values](#).

Return code	Description
S_OK	The method was successful.

Remarks

This method reads the specified file and execute the commands one line at a time using [Execute](#). If an exception occurred while executing a line, the execution will continue with the next line.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugControl4](#)
[Execute](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugControl4::ExecuteWide method

The **ExecuteWide** method executes the specified debugger commands.

Syntax

```
C++  
HRESULT ExecuteWide(  
    [in] ULONG OutputControl,  
    [in] PCWSTR Command,  
    [in] ULONG Flags  
) ;
```

Parameters

OutputControl [in]

Specifies the output control to use while executing the command. For possible values, see [DEBUG_OUTCTL_XXX](#). For more information about output, see [Input and Output](#).

Command [in]

Specifies the command string to execute. The command is interpreted like those typed into a debugger command window. This command string can contain multiple commands for the engine to execute. See [Debugger Commands](#) for the command reference.

Flags [in]

Specifies a bit field of execution options for the command. The default options are to log the command but to not send it to the output. The following table lists the bits that can be set.

Value	Description
DEBUG_EXECUTE_ECHO	The command string is sent to the output.
DEBUG_EXECUTE_NOT_LOGGED	The command string is not logged. This is overridden by DEBUG_EXECUTE_ECHO.
DEBUG_EXECUTE_NO_REPEAT	If <i>Command</i> is an empty string, do not repeat the last command, and do not save the current command string for repeat execution later.

Return value

This method can also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

This method executes the given command string. If the string has multiple commands, these methods will not return until all of the commands have been executed. This may involve waiting for the target to execute, so these methods can take an arbitrary amount of time to complete.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugControl4](#)
[ExecuteCommandFile](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugControl4::GetBreakpointById2 method

The **GetBreakpointById2** method returns the breakpoint with the specified breakpoint ID.

Syntax

```
C++
HRESULT GetBreakpointById2(
    [in]    ULONG           Id,
    [out]   PDEBUG_BREAKPOINT2 *Bp
);
```

Parameters

Id [in]

Specifies the breakpoint ID of the breakpoint to return.

Bp [out]

Receives the breakpoint.

Return value

This method can also return other error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
E_NOINTERFACE	No breakpoint was found with the given ID, or the breakpoint with the specified ID does not belong to the current process, or the breakpoint with the given ID is private (see GetFlags).

Remarks

If the specified breakpoint does not belong to the current process, the method will fail.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugControl4](#)
[IDebugBreakpoint](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugControl4::GetBreakpointByIndex2 method

The **GetBreakpointByIndex2** method returns the breakpoint located at the specified index.

Syntax

```
C++
HRESULT GetBreakpointByIndex2(
    [in]    ULONG           Index,
    [out]   PDEBUG_BREAKPOINT2 *Bp
);
```

Parameters

Index [in]

Specifies the zero-based index of the breakpoint to return. This is specific to the current process. The value of *Index* should be between zero and the total number of breakpoints minus one. The total number of breakpoints can be determined by calling [GetNumberBreakpoints](#).

Bp [out]

Receives the returned breakpoint.

Return value

This method can also return other error values. See [Return Values](#) for more details.

Return code	Description
-------------	-------------

S_OK

The method was successful.

E_NOINTERFACE

No breakpoint was found with the given index, or the breakpoint with the given index is private.

Remarks

The index and returned breakpoint are specific to the current process. The same index will return a different breakpoint if the current process is changed.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugControl4](#)
[GetNumberBreakpoints](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugControl4::GetContextStackTrace method

The **GetContextStackTrace** method returns the frames at the top of the call stack, starting with an arbitrary [register context](#) and returning the reconstructed register context for each stack frame.

Syntax

C++

```
HRESULT GetContextStackTrace(
    [in, optional] PVOID           StartContext,
    [in]                 ULONG        StartContextSize,
    [out, optional] PDEBUG_STACK_FRAME Frames,
    [in]                 ULONG        FramesSize,
    [out, optional] PVOID           FrameContexts,
    [in]                 ULONG        FrameContextsSize,
    [in]                 ULONG        FrameContextsEntrySize,
    [out, optional] PULONG          FramesFilled
);
```

Parameters

StartContext [in, optional]

Specifies the register context for the top of the stack.

StartContextSize [in]

Specifies the size, in bytes, of the *StartContext* register context.

Frames [out, optional]

Receives the stack frames. The number of elements this array holds is *FrameSize*. If *Frames* is **NULL**, this information is not returned.

FramesSize [in]

Specifies the number of items in the array *Frames*.

FrameContexts [out, optional]

Receives the reconstructed register context for each frame in the stack. The entries in this array correspond to the entries in the *Frames* array. The type of the thread context is the CONTEXT structure for the target's effective processor. If *FrameContexts* is **NULL**, this information is not returned.

FrameContextsSize [in]

Specifies the size, in bytes, of the memory pointed to by *FrameContexts*. The number of stack frames returned equals the number of contexts returned, and *FrameContextsSize* must equal *FramesSize* times *FrameContextsEntrySize*.

FrameContextsEntrySize [in]

Specifies the size, in bytes, of each frame context in *FrameContexts*.

FramesFilled [out, optional]

Receives the number of frames that were placed in the array *Frames* and contexts in *FrameContexts*. If *FramesFilled* is **NULL**, this information is not returned.

Return value

Return code	Description
S_OK	The method was successful.

This method can also return error values. For more information, see [Return Values](#).

Remarks

The stack trace returned to *Frames* and *FrameContexts* can be printed using [OutputContextStackTrace](#).

It is common for stack unwinds to restore only a subset of the registers. For example, stack unwinds will not always restore the volatile register state because the volatile registers are scratch registers and code does not need to preserve them. Registers that are not restored on unwind are left as the last value restored, so care should be taken when using the register state that might not be restored by an unwind.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h or Ntddk.h)

IDebugControl4::GetEventFilterCommandWide method

The **GetEventFilterCommandWide** method returns the debugger command that the engine will execute when a specified event occurs.

Syntax

```
C++  
HRESULT GetEventFilterCommandWide(  
    [in]          ULONG   Index,  
    [out, optional] PWSTR   Buffer,  
    [in]          ULONG   BufferSize,  
    [out, optional] PULONG  CommandSize  
) ;
```

Parameters

Index [in]

Specifies the index of the event filter. *Index* can take any value between zero and one less than the total number of event filters returned by [GetNumberEventFilters](#) (inclusive). For more information about the index of the filters, see Index and Exception Code.

Buffer [out, optional]

Receives the debugger command that the engine will execute when the event occurs.

BufferSize [in]

Specifies the size, in characters, of the buffer that *Buffer* specifies.

CommandSize [out, optional]

Receives the size in characters of the command. If *CommandSize* is **NULL**, this information is not returned.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

For more information about event filters, see [Event Filters](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugControl4](#)
[sx, sx, sx, sxn \(Set Exceptions\)](#)
[SetEventFilterCommand](#)
[GetExceptionFilterSecondCommand](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugControl4::GetEventFilterTextWide method

The **GetEventFilterTextWide** method returns a short description of an event for a specific filter.

Syntax

C++

```
HRESULT GetEventFilterTextWide(
    [in]          ULONG   Index,
    [out, optional] PWSTR  Buffer,
    [in]          ULONG   BufferSize,
    [out, optional] PULONG TextSize
);
```

Parameters

Index [in]

Specifies the index of the event filter whose description will be returned. Only the specific filters have a description attached to them; *Index* must refer to a specific filter.

Buffer [out, optional]

Receives the description of the specific filter.

BufferSize [in]

Specifies the size, in characters, of the buffer that *Buffer* specifies.

TextSize [out, optional]

Receives the size of the event description. If *TextSize* is **NULL**, this information is not returned.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
E_NOINTERFACE	<i>Index</i> did not refer to a specific filter. This can occur if <i>Index</i> refers to an arbitrary exception filter.

Remarks

For more information about [event filters](#), see [Event Filters](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

IDebugControl4::GetEventIndexDescriptionWide method

The **GetEventIndexDescriptionWide** method describes the specified event in a static list of events for the current target.

Syntax

```
C++
HRESULT GetEventIndexDescriptionWide(
    [in]           ULONG   Index,
    [in]           ULONG   Which,
    [in, optional] PWSTR   Buffer,
    [in]           ULONG   BufferSize,
    [out, optional] PULONG DescSize
);
```

Parameters

Index [in]

Specifies the index of the event whose description will be returned.

Which [in]

Specifies which piece of the event description to return. Currently only DEBUG_EINDEX_NAME is supported; this returns the name of the event.

Buffer [in, optional]

Receives the description of the event. If *Buffer* is **NULL**, this information is not returned.

BufferSize [in]

Specifies the size, in characters, of the *Buffer* buffer.

DescSize [out, optional]

Receives the size, in characters, of the description. If *DescSize* is **NULL**, this information is not returned.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

The amount of descriptive information available for a particular target varies depending on the type of the target.

Requirements

Target platform
Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugControl4](#)
[GetNumberEvents](#)
[GetCurrentEventIndex](#)

IDebugControl4::GetExceptionFilterSecondCommandWide method

The **GetExceptionFilterSecondCommandWide** method returns the command that will be executed by the [debugger engine](#) upon the second chance of a specified *exception*.

Syntax

```
C++  
HRESULT GetExceptionFilterSecondCommandWide(  
    [in]          ULONG   Index,  
    [out, optional] PWSTR  Buffer,  
    [in]          ULONG   BufferSize,  
    [out, optional] PULONG CommandSize  
) ;
```

Parameters

Index [in]

Specifies the index of the exception filter whose second-chance command will be returned. *Index* can also refer to the default exception filter to return the second-chance command for those exceptions that do not have a specific or arbitrary exception filter.

Buffer [out, optional]

Receives the second-chance command for the exception filter.

BufferSize [in]

Specifies the size, in characters, of the buffer that *Buffer* specifies.

CommandSize [out, optional]

Receives the size, in characters, of the second-chance command for the exception filter. If *CommandSize* is **NULL**, this information is not returned.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

Only exception filters support a second-chance command. If *Index* refers to a [specific event filter](#), the command returned to *Buffer* will be empty. The returned command will also be empty if no second-chance command has been set for the specified exception.

For more information about [event filters](#), see [Event Filters](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

IDebugControl4::GetExpressionSyntaxNamesWide method

The **GetExpressionSyntaxNamesWide** method returns the full and abbreviated names of an expression syntax.

Syntax

```
C++  
HRESULT GetExpressionSyntaxNamesWide(  
    [in]           ULONG   Index,  
    [out, optional] PWSTR   FullNameBuffer,  
    [in]           ULONG   FullNameBufferSize,  
    [out, optional] PULONG  FullNameSize,  
    [out, optional] PWSTR   AbbrevNameBuffer,  
    [in]           ULONG   AbbrevNameBufferSize,  
    [out, optional] PULONG  AbbrevNameSize  
) ;
```

Parameters

Index [in]

Specifies the index of the expression syntax. *Index* should be between zero and the number of expression syntaxes returned by [GetNumberExpressionSyntaxes](#) minus one.

FullNameBuffer [out, optional]

Receives the full name of the expression syntax. If *FullNameBuffer* is **NULL**, this information is not returned.

FullNameBufferSize [in]

Specifies the size, in characters, of the buffer *FullNameBuffer*.

FullNameSize [out, optional]

Receives the size, in characters, of the full name of the expression syntax. If *FullNameSize* is **NULL**, this information is not returned.

AbbrevNameBuffer [out, optional]

Receives the abbreviated name of the expression syntax. If *AbbrevNameBuffer* is **NULL**, this information is not returned.

AbbrevNameBufferSize [in]

Specifies the size, in characters, of the buffer *AbbrevNameBufferSize*.

AbbrevNameSize [out, optional]

Receives the size, in characters, of the abbreviated name of the expression syntax. If *AbbrevNameSize* is **NULL**, this information is not returned.

Return value

This method can also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
S_FALSE	The method was successful. However, either <i>FullNameBufferSize</i> or <i>AbbrevNameBufferSize</i> was smaller than the size of the respective expression syntax name, and the name was truncated to fit inside the buffer.

Remarks

Currently, there are two expression syntaxes, their full names are "Microsoft Assembler expressions" and "C++ source expressions." The corresponding abbreviated expression syntaxes are "MASM" and "C++."

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

IDebugControl4::GetExtensionByPathWide method

The **GetExtensionByPathWide** method returns the handle for an already loaded extension library.

Syntax

```
C++  
HRESULT GetExtensionByPathWide(  
    [in]  PCWSTR Path,  
    [out] PULONG64 Handle  
) ;
```

Parameters

Path [in]

Specifies the fully qualified path and file name of the extension library.

Handle [out]

Receives the handle of the extension library.

Return value

This method can also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

Extension libraries are loaded into the [host engine](#), which is where this method looks for the requested extension library. *Path* is a path and file name for the host engine.

For more information on using extension libraries, see [Calling Extensions and Extension Functions](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugControl4](#)
[AddExtension](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugControl4::GetExtensionFunctionWide method

The **GetExtensionFunctionWide** method returns a pointer to an extension function from an extension library.

Syntax

```
C++  
HRESULT GetExtensionFunctionWide(  
    [in]  ULONG64 Handle,  
    [in]  PCWSTR FuncName,  
    [out] FARPROC *Function  
) ;
```

Parameters

Handle [in]

Specifies the handle of the extension library that contains the extension function. If *Handle* is zero, the engine will walk the extension library chain searching for the extension function.

FuncName [in]

Specifies the name of the extension function to return. When searching the extension libraries for the function, the debugger engine will prepend "_EFN_" to the name. For example, if *FuncName* is "SampleFunction", the engine will search the extension libraries for "_EFN_SampleFunction".

Function [out]

Receives the extension function.

Return value

This method can also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

Extension libraries are loaded into the host engine and extension functions cannot be called remotely. The current client must not be a debugging client, it must belong to the host engine.

The extension function can have any function prototype. In order for any program to call this extension function, the extension function should be cast to the correct prototype.

For more information on using extension functions, see [Calling Extensions and Extension Functions](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

IDebugControl4::GetLastEventInformationWide method

The **GetLastEventInformationWide** method returns information about the last event that occurred in a target.

Syntax

C++

```
HRESULT GetLastEventInformationWide(
    [out]          PULONG Type,
    [out]          PULONG ProcessId,
    [out]          PULONG ThreadId,
    [out, optional] PVOID ExtraInformation,
    [in]           ULONG ExtraInformationSize,
    [out, optional] PULONG ExtraInformationUsed,
    [out, optional] PWSTR Description,
    [in]           ULONG DescriptionSize,
    [out, optional] PULONG DescriptionUsed
);
```

Parameters

Type [out]

Receives the type of the last event generated by the target. For a list of possible types, see [DEBUG_EVENT_XXX](#).

ProcessId [out]

Receives the process ID of the process in which the event occurred. If this information is not available, DEBUG_ANY_ID will be returned instead.

ThreadId [out]

Receives the thread ID of the thread in which the last event occurred. If this information is not available, DEBUG_ANY_ID will be returned instead.

ExtraInformation [out, optional]

Receives extra information about the event. The contents of this extra information depends on the type of the event as indicated by the returned *Type* parameter. For example, if *Type* is breakpoint, *ExtraInformation* contains a DEBUG_LAST_EVENT_INFO_BREAKPOINT; if *Type* is Exception, *ExtraInformation* contains a DEBUG_LAST_EVENT_INFO_EXCEPTION. Refer to [DEBUG_EVENT_XXX](#) for the complete list of event types and the dbgeng.h header file for the structure definitions for each event type.

If *ExtraInformation* is **NULL**, this information is not returned.

ExtraInformationSize [in]

Specifies the size, in bytes, of the buffer that *ExtraInformation* specifies.

ExtraInformationUsed [out, optional]

Receives the size, in bytes, of extra information. If *ExtraInformationUsed* is **NULL**, this information is not returned.

Description [out, optional]

Receives the description of the event. If *Description* is **NULL**, this information is not returned.

DescriptionSize [in]

Specifies the size, in characters, of the buffer that *Description* specifies.

DescriptionUsed [out, optional]

Receives the size in characters of the description of the event. If *DescriptionUsed* is **NULL**, this information is not returned.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
S_FALSE	The method was successful. However, either <i>ExtraInformationSize</i> or <i>DescriptionSize</i> were smaller than the size of the respective data or string and the data or string was truncated to fit inside the buffer.

Remarks

For thread and process creation events, the thread ID and process ID returned to *ThreadId* and *ProcessId* are for the newly created thread or process.

For more information about the last event, see the topic [Event Information](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

IDebugControl4::GetLogFileWide method

The **GetLogFileWide** method returns the name of the currently open log file.

Syntax

C++

```
HRESULT GetLogFileWide(
    [out, optional] PWSTR Buffer,
    [in]          ULONG BufferSize,
    [out, optional] PULONG FileSize,
    [out]          PBOOL Append
);
```

Parameters

Buffer [out, optional]

Receives the name of the currently open log file. If *Buffer* is **NULL**, this information is not returned.

BufferSize [in]

Specifies the size, in characters, of the *Buffer* buffer.

FileSize [out, optional]

Receives the size, in characters, of the name of the log file. If *FileSize* is **NULL**, this information is not returned.

Append [out]

Receives **TRUE** if log messages are appended to the log file, or **FALSE** if the contents of the log file were discarded when the file was opened.

Return value

This method can also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
S_FALSE	The method was successful. However, the name of the log file was too long to fit in the <i>Buffer</i> buffer so the name was truncated.
E_NOINTERFACE	There is no currently open log file.

Remarks

GetLogFile and **GetLogFileWide** behave the same way as [GetLogFile2](#) and [GetLogFile2Wide](#) with *Append* receiving only the information about the DEBUG_LOG_APPEND flag.

For more information about log files, see [Using Input and Output](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugControl4::GetLogFile2 method

The **GetLogFile2** method returns the name of the currently open log file.

Syntax

C++

```
HRESULT GetLogFile2(
    [out, optional] PSTR    Buffer,
    [in]        ULONG   BufferSize,
    [out, optional] PULONG  FileSize,
    [out]        ULONG   Flags
);
```

Parameters

Buffer [out, optional]

Receives the name of the currently open log file. If *Buffer* is **NULL**, this information is not returned.

BufferSize [in]

Specifies the size, in characters, of the *Buffer* buffer.

FileSize [out, optional]

Receives the size, in characters, of the name of the log file. If *FileSize* is **NULL**, this information is not returned.

Flags [out]

Receives the bit-flags that were used when opening the log file. See the *Flags* parameter of [OpenLogFile2](#) for a description of these flags.

Return value

This method can also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
S_FALSE	The method was successful. However, the name of the log file was too long to fit in the <i>Buffer</i> buffer so the name was truncated.
E_NOINTERFACE	There is no currently open log file.

Remarks

For more information about log files, see [Using Input and Output](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugControl4::GetLogFile2Wide method

The **GetLogFile2Wide** method returns the name of the currently open log file.

Syntax

```
C++  
HRESULT GetLogFile2Wide(  
    [out, optional] PWSTR Buffer,  
    [in]          ULONG BufferSize,  
    [out, optional] PULONG FileSize,  
    [out]           PULONG Flags  
) ;
```

Parameters

Buffer [out, optional]

Receives the name of the currently open log file. If *Buffer* is **NULL**, this information is not returned.

BufferSize [in]

Specifies the size, in characters, of the *Buffer* buffer.

FileSize [out, optional]

Receives the size, in characters, of the name of the log file. If *FileSize* is **NULL**, this information is not returned.

Flags [out]

Receives the bit-flags that were used when opening the log file. See the *Flags* parameter of [OpenLogFile2](#) for a description of these flags.

Return value

This method can also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
S_FALSE	The method was successful. However, the name of the log file was too long to fit in the <i>Buffer</i> buffer so the name was truncated.
E_NOINTERFACE	There is no currently open log file.

Remarks

For more information about log files, see [Using Input and Output](#).

Requirements

Target platform

IDebugControl4::GetProcessorTypeNamesWide method

The **GetProcessorTypeNamesWide** method returns the full name and abbreviated name of the specified processor type.

Syntax

```
C++  
HRESULT GetProcessorTypeNamesWide(  
    [in]          ULONG Type,  
    [out, optional] PWSTR FullNameBuffer,  
    [in]          ULONG FullNameBufferSize,  
    [out, optional] PULONG FullNameSize,  
    [out, optional] PWSTR AbbrevNameBuffer,  
    [in]          ULONG AbbrevNameBufferSize,  
    [out, optional] PULONG AbbrevNameSize  
) ;
```

Parameters

Type [in]

Specifies the type of the processor whose name is requested. See [GetActualProcessorType](#) for a list of possible values.

FullNameBuffer [out, optional]

Receives the full name of the processor type. If *FullNameBuffer* is **NULL**, this information is not returned.

FullNameBufferSize [in]

Specifies the size, in characters, of the buffer that *FullNameBuffer* specifies.

FullNameSize [out, optional]

Receives the size in characters of the full name of the processor type. If *FullNameSize* is **NULL**, this information is not returned.

AbbrevNameBuffer [out, optional]

Receives the abbreviated name of the processor type. If *AbbrevNameBuffer* is **NULL**, this information is not returned.

AbbrevNameBufferSize [in]

Specifies the size, in characters, of the buffer that *AbbrevNameBuffer* specifies.

AbbrevNameSize [out, optional]

Receives the size in characters of the abbreviated name of the processor type. If *AbbrevNameSize* is **NULL**, this information is not returned.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
S_FALSE	The method was successful. However, at least one of <i>FullNameBuffer</i> or <i>AbbrevNameBuffer</i> was too small for the corresponding name, so the name was truncated.

Remarks

For more information, see [Target Information](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

IDebugControl4::GetPromptTextWide method

The **GetPromptTextWide** method returns the standard prompt text that will be prepended to the formatted output specified in the [OutputPrompt](#) and [OutputPromptVaList](#) methods.

Syntax

```
C++
HRESULT GetPromptTextWide(
    [out, optional] PWSTR Buffer,
    [in]           ULONG   BufferSize,
    [out, optional] PULONG TextSize
);
```

Parameters

Buffer [out, optional]

Receives the prompt text. If *Buffer* is **NULL**, this information is not returned.

BufferSize [in]

Specifies the size, in characters, of the *Buffer* buffer.

TextSize [out, optional]

Receives the size, in characters, of the prompt text. If *TextSize* is **NULL**, this information is not returned.

Return value

This method can also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
S_FALSE	The method was successful. However, the prompt text was too large to fit into the <i>Buffer</i> buffer and the text was truncated.

Remarks

For more information about prompting the user, see [Using Input and Output](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

IDebugControl4::GetSpecificFilterArgumentWide method

The **GetSpecificFilterArgumentWide** method returns the value of filter argument for the specific filters that have an argument.

Syntax

```
C++  
HRESULT GetSpecificFilterArgumentWide(  
    [in]          ULONG Index,  
    [out, optional] PWSTR Buffer,  
    [in]          ULONG BufferSize,  
    [out, optional] PULONG ArgumentSize  
) ;
```

Parameters

Index [in]

Specifies the index of the specific filter whose argument will be returned. *Index* must be the index of a specific filter that has an argument.

Buffer [out, optional]

Receives the argument for the specific filter. The interpretation of the argument depends on the specific filter.

BufferSize [in]

Specifies the size, in characters, of the buffer that *Buffer* specifies.

ArgumentSize [out, optional]

Receives the size, in characters, of the argument for the specific filter.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
E_INVALIDARG	<i>Index</i> does not refer to a specific filter that has an argument.

Remarks

For a list of specific filters that have argument and the interpretation of those arguments, see [Event Filters](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

© 2016 Microsoft. All rights reserved.

IDebugControl4::GetStoredEventInformation method

The **GetStoredEventInformation** method retrieves information about an event of interest available in the current target.

Syntax

```
C++  
HRESULT GetStoredEventInformation(  
    [out]          PULONG Type,  
    [out]          PULONG ProcessId,  
    [out]          PULONG ThreadId,  
    [out, optional] PVOID Context,  
    [in]           ULONG ContextSize,  
    [out, optional] PULONG ContextUsed,  
    [out, optional] PVOID ExtraInformation,  
    [in]           ULONG ExtraInformationSize,  
    [out, optional] PULONG ExtraInformationUsed  
) ;
```

Parameters

Type [out]

Receives the type of the stored event. For a list of possible types, see [DEBUG_EVENT_XXX](#).

ProcessId [out]

Receives the process ID of the process in which the event occurred. If this information is not available, DEBUG_ANY_ID will be returned instead.

ThreadId [out]

Receives the thread ID of the thread in which the last event occurred. If this information is not available, DEBUG_ANY_ID will be returned instead.

Context [out, optional]

Receives the [thread context](#) of the stored event. The type of the thread context is the CONTEXT structure for the target's effective processor at the time of the event. The *Context* buffer must be large enough to hold this structure. If *Context* is **NULL**, this information is not returned.

ContextSize [in]

Specifies the size, in bytes, of the buffer that *Context* specifies.

ContextUsed [out, optional]

Receives the size in bytes of the context. If *ContextUsed* is **NULL**, this information is not returned.

ExtraInformation [out, optional]

Receives extra information about the event. The contents of this extra information depends on the type of the event. If *ExtraInformation* is **NULL**, this information is not returned.

ExtraInformationSize [in]

Specifies the size, in bytes, of the buffer that *ExtraInformation* specifies.

ExtraInformationUsed [out, optional]

Receives the size in bytes of extra information. If *ExtraInformationUsed* is **NULL**, this information is not returned.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

Many targets do not have an event of interest.

If the target is a user-mode minidump file, the dump file generator may store an additional event. Typically, this is the event that provoked the generator to save the dump file.

For more information, see the topic [Event Information](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h or Ntddk.h)

See also

[IDebugControl4](#)
[GetLastEventInformation](#)

IDebugControl4::GetSystemVersionString method

The **GetSystemVersionString** method returns a string that describes the target's operating system version.

Syntax

C++

```
HRESULT GetSystemVersionString(
    [in]          ULONG Which,
    [out, optional] PSTR  Buffer,
    [in]          ULONG BufferSize,
    [out, optional] PULONG StringSize
);
```

Parameters

Which [in]

Specifies which version string to return. The possible values are listed in the following table.

Value	Version string
DEBUG_SYSVERSTR_SERVICE_PACK	Returns a description of the service pack for the target's operating system. For example, "Service Pack 1".
DEBUG_SYSVERSTR_BUILD	Returns a description of the target's operating system build version. For example, "kernel32.dll version: 5.1.2600.1106 (xpsp1.020828-1920)".

Buffer [out, optional]

Receives the version string. If *Buffer* is **NULL**, this information is not returned.

BufferSize [in]

Specifies the size, in characters, of the buffer that *Buffer* specifies.

StringSize [out, optional]

Receives the size, in characters, of the string that identifies the build. If *StringSize* is **NULL**, this information is not returned.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
S_FALSE	The method was successful. However, the buffer was too small, so the string was truncated.

Remarks

For more information, see [Target Information](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugControl4](#)
[GetSystemVersion](#)
[GetSystemVersionValues](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugControl4::GetSystemVersionStringWide method

The **GetSystemVersionStringWide** method returns a string that describes the target's operating system version.

Syntax

```
C++  
HRESULT GetSystemVersionStringWide(  
    [in]          ULONG Which,  
    [out, optional] PWSTR Buffer,  
    [in]          ULONG BufferSize,  
    [out, optional] PULONG StringSize  
) ;
```

Parameters

Which [in]

Specifies which version string to return. The possible values are listed in the following table.

Value	Version string
DEBUG_SYSVERSTR_SERVICE_PACK	Returns a description of the service pack for the target's operating system. For example, "Service Pack 1".
DEBUG_SYSVERSTR_BUILD	Returns a description of the target's operating system build version. For example, "kernel32.dll version: 5.1.2600.1106 (xpsp1.020828-1920)".

Buffer [out, optional]

Receives the version string. If *Buffer* is **NULL**, this information is not returned.

BufferSize [in]

Specifies the size, in characters, of the buffer that *Buffer* specifies.

StringSize [out, optional]

Receives the size, in characters, of the string that identifies the build. If *StringSize* is **NULL**, this information is not returned.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
S_FALSE	The method was successful. However, the buffer was too small, so the string was truncated.

Remarks

For more information, see [Target Information](#).

Requirements

Target platform
Header Dbgeng.h (include Dbgeng.h)

IDebugControl4::GetSystemVersionValues method

The **GetSystemVersionValues** method returns version number information for the current target.

Syntax

C++

```
HRESULT GetSystemVersionValues(
    [out]          PULONG PlatformId,
    [out]          PULONG Win32Major,
    [out]          PULONG Win32Minor,
    [out, optional] PULONG KdMajor,
    [out, optional] PULONG KdMinor
);
```

Parameters

PlatformId [out]

Receives the platform ID. *PlatformId* is always VER_PLATFORM_WIN32_NT for NT-based Windows.

Win32Major [out]

Receives the major version number of the target's operating system. For Windows 2000, Windows XP, and Windows Server 2003, this number is 5. For Windows Vista, Windows 7, and Windows 8, this number is 6.

Win32Minor [out]

Receives the minor version number for the target's operating system. For Windows 2000 this is 0; for Windows XP, 1; for Windows Server 2003, 2. For Windows Vista, this is 0; for Windows 7, 1; for Windows 8, 2.

KdMajor [out, optional]

Receives 0xF if the target's operating system is a free build, and 0xC if it is a checked build.

KdMinor [out, optional]

Receives the build number for the target's operating system.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

For more information, see [Target Information](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugControl4::GetTextMacroWide method

The `GetTextMacroWide` method returns the value of a fixed-name alias.

Syntax

```
C++  
HRESULT GetTextMacroWide(  
    [in]           ULONG Slot,  
    [out, optional] PWSTR Buffer,  
    [in]           ULONG BufferSize,  
    [out, optional] PULONG MacroSize  
) ;
```

Parameters

Slot [in]

Specifies the number of the fixed-name alias. *Slot* can take the values 0, 1, ..., 9, that represent the fixed-name aliases `$u0`, `$u1`, ..., `$u9`.

Buffer [out, optional]

Receives the value of the alias specified by *Slot*. If *Buffer* is `NULL`, this information is not returned.

BufferSize [in]

Specifies the size, in characters, of the *Buffer* buffer.

MacroSize [out, optional]

Receives the size, in characters, of the value of the alias.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
<code>S_OK</code>	The method was successful.

Remarks

Before executing commands or evaluating expressions, the debugger engine will replace the alias specified by *Slot* with the value of the alias (returned to the *Buffer* buffer).

For an overview of aliases used by the [debugger engine](#), see [Using Aliases](#). For more information about using aliases with the debugger engine API, see [Interacting with the Engine](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugControl4::GetTextReplacementWide method

The `GetTextReplacementWide` method returns the value of a user-named alias or an automatic alias.

Syntax

```
C++
```

```
HRESULT GetTextReplacementWide(
```

```
[in, optional] PCWSTR SrcText,
[in]          ULONG Index,
[out, optional] PWSTR SrcBuffer,
[in]          ULONG SrcBufferSize,
[out, optional] PULONG SrcSize,
[out, optional] PWSTR DstBuffer,
[in]          ULONG DstBufferSize,
[out, optional] PULONG DstSize
);
```

Parameters

SrcText [in, optional]

Specifies the name of the alias. The engine first searches the user-named aliases for one with this name. Then, if no match is found, the automatic aliases are searched. If *SrcText* is **NULL**, *Index* is used to specify the alias.

Index [in]

Specifies the index of an alias. The indexes of the user-named aliases come before the indexes of the automatic aliases. *Index* is only used if *SrcText* is **NULL**. *Index* can be used along with [GetNumberTextReplacements](#) to iterate over all the user-named and automatic aliases.

SrcBuffer [out, optional]

Receives the name of the alias. This is the name specified in *SrcText*, if *SrcText* is not **NULL**. If *SrcBuffer* is **NULL**, this information is not returned.

SrcBufferSize [in]

Specifies the size, in characters, of the *SrcBuffer* buffer.

SrcSize [out, optional]

Receives the size, in characters, of the name of the alias. If *SrcSize* is **NULL**, this information is not returned.

DstBuffer [out, optional]

Receives the value of the alias specified by *SrcText* and *Index*. If *DstBuffer* is **NULL**, this information is not returned.

DstBufferSize [in]

Specifies the size, in characters, of the *DstBuffer* buffer.

DstSize [out, optional]

Receives the size, in characters, of the value of the alias. If *DstSize* is **NULL**, this information is not returned.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

Before executing commands or evaluating expressions, the debugger engine will replace the alias specified by *SrcBuffer* with the value of the alias (specified by *DstBuffer*).

For an overview of aliases used by the [debugger engine](#), see [Using Aliases](#). For more information about using aliases with the debugger engine API, see [Interacting with the Engine](#).

Requirements

Target platform

IDebugControl4::InputWide method

The **InputWide** method requests an input string from the [debugger engine](#).

Syntax

```
C++  
HRESULT InputWide(  
    [out]          PWSTR  Buffer,  
    [in]           ULONG   BufferSize,  
    [out, optional] PULONG InputSize  
) ;
```

Parameters

Buffer [out]

Receives the input string from the engine.

BufferSize [in]

Specifies the size, in characters, of the buffer that *Buffer* specifies.

InputSize [out, optional]

Receives the number of characters returned in *Buffer*. If *InputSize* is **NULL**, this information is not returned.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
S_FALSE	The method was successful. However, the buffer was not big enough to hold the whole input string and it was truncated.

Remarks

For an overview of input in the debugger engine, see [Input and Output](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugControl4::OpenLogFile2 method

The **OpenLogFile2** method opens a log file that will receive output from the [client objects](#).

Syntax

```
C++  
HRESULT OpenLogFile2(  
    [in] PCSTR File,  
    [in] ULONG Flags  
) ;
```

Parameters

File [in]

Specifies the name of the log file. *File* can include a relative or absolute path; relative paths are relative to the directory in which the debugger was started. If the file does not exist, it will be created.

Flags [in]

Specifies the bit-flags that control the nature of the log file. *Flags* can contain flags from the following table.

Flag	Effect when set
DEBUG_LOG_APPEND	Output will be appended to the log file instead of discarding the contents of the log file.
DEBUG_LOG_UNICODE	The format of the log file will be Unicode instead of ASCII.

Alternatively, *Flags* can be set to DEBUG_LOG_DEFAULT for the default set of options that contains none of the flags.

Return value

This method can also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

Only one log file can be open at a time. If there is already a log file open, it will be closed.

For more information about log files, see [Using Input and Output](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugControl4::OpenLogFile2Wide method

The OpenLogFile2Wide method opens a log file that will receive output from the [client objects](#).

Syntax

C++
HRESULT OpenLogFile2Wide(
 [in] PCWSTR File,
 [in] ULONG Flags
) ;

Parameters

File [in]

Specifies the name of the log file. *File* can include a relative or absolute path; relative paths are relative to the directory in which the debugger was started. If the file does not exist, it will be created.

Flags [in]

Specifies the bit-flags that control the nature of the log file. *Flags* can contain flags from the following table.

Flag	Effect when set
DEBUG_LOG_APPEND	Output will be appended to the log file instead of discarding the contents of the log file.
DEBUG_LOG_UNICODE	The format of the log file will be Unicode instead of ASCII.

Alternatively, *Flags* can be set to DEBUG_LOG_DEFAULT for the default set of options that contains none of the flags.

Return value

This method can also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

Only one log file can be open at a time. If there is already a log file open, it will be closed.

For more information about log files, see [Using Input and Output](#).

IDebugControl4::OpenLogFileWide method

The **OpenLogFileWide** method opens a log file that will receive output from the [client objects](#).

Syntax

```
C++  
HRESULT OpenLogFileWide(  
    [in] PCWSTR File,  
    [in] BOOL Append  
) ;
```

Parameters

File [in]

Specifies the name of the log file. *File* can include a relative or absolute path; relative paths are relative to the directory in which the debugger was started. If the file does not exist, it will be created.

Append [in]

Specifies whether or not to append log messages to an existing log file. If **TRUE**, log messages will be appended to the file; if **FALSE**, the contents of any existing file matching *File* are discarded.

Return value

This method can also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

OpenLogFile and **OpenLogFileWide** behave the same way as [OpenLogFile2](#) and [OpenLogFile2Wide](#) with *Flags* set to DEBUG_LOG_APPEND if *Append* is **TRUE** and

DEBUG_LOG_DEFAULT otherwise.

Only one log file can be open at a time. If there is already a log file open, it will be closed.

IDebugControl4::OutputContextStackTrace method

The **OutputContextStackTrace** method prints the call stack specified by an array of stack frames and corresponding register contexts.

Syntax

```
C++  
HRESULT OutputContextStackTrace(  
    [in] ULONG             OutputControl,  
    [in] PDEBUG_STACK_FRAME Frames,  
    [in] ULONG             FramesSize,  
    [in] PVOID              FrameContexts,  
    [in] ULONG             FrameContextsSize,  
    [in] ULONG             FrameContextsEntrySize,  
    [in] ULONG             Flags  
) ;
```

Parameters

OutputControl [in]

Specifies where to send the output. For possible values, see [DEBUG_OUTCTL_XXX](#).

Frames [in]

Specifies the array of stack frames to output. The number of elements in this array is *FramesSize*. If *Frames* is **NULL**, the current stack frame is used.

FramesSize [in]

Specifies the number of frames to output.

FrameContexts [in]

Specifies the register context for each frame in the stack. The entries in this array correspond to the entries in the *Frames* array. The type of the thread context is the CONTEXT structure for the target's effective processor.

FrameContextsSize [in]

Specifies the size, in bytes, of the memory pointed to by *FrameContexts*. The number of stack frames must equal the number of contexts, and *FrameContextsSize* must equal *FramesSize* multiplied by *FrameContextsEntrySize*.

FrameContextsEntrySize [in]

Specifies the size, in bytes, of each frame context in *FrameContexts*.

Flags [in]

Specifies bit flags that determine what information to output for each frame. *Flags* can be any combination of values from the following table.

Flag	Description
------	-------------

DEBUG_STACK_ARGUMENTS	Displays the first three pieces of stack memory at the frame of each call. On platforms where arguments are passed on the stack, and the code for the frame uses stack arguments, these values will be the arguments to the function.
DEBUG_STACK_FUNCTION_INFO	Displays information about the function that corresponds to the frame. This includes calling convention and frame pointer omission (FPO) information.
DEBUG_STACK_SOURCE_LINE	Displays source line information for each frame of the stack trace.
DEBUG_STACK_FRAME_ADDRESSES	Displays the return address, previous frame address, and other relevant addresses for each frame.
DEBUG_STACK_COLUMN_NAMES	Displays column names.
DEBUG_STACK_NONVOLATILE_REGISTERS	Displays the non-volatile register context for each frame. This is only meaningful for some platforms.
DEBUG_STACK_FRAME_NUMBERS	Displays frame numbers.
DEBUG_STACK_PARAMETERS	Displays parameter names and values as given in symbol information.
DEBUG_STACK_FRAME_ADDRESSES_RA_ONLY	Displays just the return address in the stack frame addresses.
DEBUG_STACK_FRAME_MEMORY_USAGE	Displays the number of bytes that separate the frames.
DEBUG_STACK_PARAMETERS_NEWLINE	Displays each parameter and its type and value on a new line.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

The array of stack frames can be obtained using [GetContextStackTrace](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h or Ntddk.h)

IDebugControl4::OutputPromptVaListWide method

The [OutputPromptVaListWide](#) method formats and sends a user prompt to the [output callback objects](#).

Syntax

```
C++
HRESULT OutputPromptVaListWide(
    [in]          ULONG   OutputControl,
    [in, optional] PCWSTR  Format,
    [in]          va_list Args
);
```

Parameters

OutputControl [in]

Specifies an output control that determines which of the client's output callbacks will receive the output. For possible values, see [DEBUG_OUTCTL XXX](#).

Format [in, optional]

Specifies the format string, as in **printf**. Typically, conversion characters work exactly as they do in C. For the floating-point conversion characters, the 64-bit argument is interpreted as a 32-bit floating-point number unless the **I** modifier is used.

The **%p** conversion character is supported, but it represents a pointer in a target's address space. It might not have any modifiers and it uses the debugger's internal address formatting. The following additional conversion characters are supported.

Character	Argument type	Argument	Text printed
%p	ULONG64	Pointer in an address space.	The value of the pointer.
%N	DWORD_PTR (32 or 64 bits, depending on the host's architecture)	Pointer in the host's virtual address space.	The value of the pointer. (This is equivalent to the standard C %p character.)
%I	ULONG64	Any 64-bit value.	The specified value. If this is greater than 0xFFFFFFFF, it is printed as a 64-bit value; otherwise, it is printed as a 32-bit value.
%ma	ULONG64	Address of a NULL-terminated ASCII string in the process's virtual address space.	The specified string.
%mu	ULONG64	Address of a NULL-terminated Unicode string in the process's virtual address space.	The specified string.
%msa	ULONG64	Address of an ANSI_STRING structure in the process's virtual address space.	The specified string.
%msu	ULONG64	Address of a UNICODE_STRING structure in the process's virtual address space.	The specified string.
%y	ULONG64	Address in the process's virtual address space of an item with symbol information.	String that contains the name of the specified symbol (and displacement, if any).
%ly	ULONG64	Address in the process's virtual address space of an item with symbol information.	String that contains the name of the specified symbol (and displacement, if any), as well as any available source line information.

If *Format* is **NULL**, only the standard prompt text is sent to the output callbacks.

Args [in]

Specifies additional parameters that represent values to be inserted into the output during formatting. *Args* must be initialized using **va_start**. This method does not call **va_end**.

Return value

This method can also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

OutputPromptVaList and **OutputPromptVaListWide** can be used to prompt the user for input.

The standard prompt will be sent to the output callbacks before the formatted text described by *Format*. The contents of the standard prompt is returned by the method [GetPromptText](#).

The prompt text is sent to the output callbacks with the **DEBUG_OUTPUT_PROMPT** output mask set.

For more information about prompting the user, see [Using Input and Output](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h or Stdarg.h)

IDebugControl4::OutputPromptWide method

The **OutputPromptWide** method formats and sends a user prompt to the [output callback objects](#).

Syntax

C++

```

HRESULT OutputPromptWide(
    [in]           ULONG   OutputControl,
    [in, optional] PCWSTR Format,
    ...
);

```

Parameters

OutputControl [in]

Specifies an output control that determines which of the client's output callbacks will receive the output. For possible values, see [DEBUG_OUTCTL_XXX](#).

Format [in, optional]

Specifies the format string, as in **printf**. Typically, conversion characters work exactly as they do in C. For the floating-point conversion characters, the 64-bit argument is interpreted as a 32-bit floating-point number unless the **I** modifier is used.

The **%p** conversion character is supported, but it represents a pointer in a target's address space. It might not have any modifiers and it uses the debugger's internal address formatting. The following additional conversion characters are supported.

Character	Argument type	Argument	Text printed
%p	ULONG64	Pointer in an address space.	The value of the pointer.
%N	DWORD_PTR (32 or 64 bits, depending on the host's architecture)	Pointer in the host's virtual address space.	The value of the pointer. (This is equivalent to the standard C %p character.)
%I	ULONG64	Any 64-bit value.	The specified value. If this is greater than 0xFFFFFFFF, it is printed as a 64-bit value; otherwise, it is printed as a 32-bit value.
%ma	ULONG64	Address of a NULL-terminated ASCII string in the process' virtual address space.	The specified string.
%mu	ULONG64	Address of a NULL-terminated Unicode string in the process's virtual address space.	The specified string.
%msa	ULONG64	Address of an ANSI_STRING structure in the process's virtual address space.	The specified string.
%msu	ULONG64	Address of a UNICODE_STRING structure in the process's virtual address space.	The specified string.
%y	ULONG64	Address in the process's virtual address space of an item with symbol information.	String that contains the name of the specified symbol (and displacement, if any).
%ly	ULONG64	Address in the process's virtual address space of an item with symbol information.	String that contains the name of the specified symbol (and displacement, if any), as well as any available source line information.

If *Format* is **NULL**, only the standard prompt text is sent to the output callbacks.

...

Specifies additional parameters that represent values to be inserted into the output during formatting.

Return value

Return code	Description
S_OK	The method was successful.

This method can also return error values. See [Return Values](#) for more details.

Remarks

OutputPrompt and **OutputPromptWide** can be used to prompt the user for input.

The standard prompt will be sent to the output callbacks before the formatted text described by *Format*. The contents of the standard prompt is returned by the method [GetPromptText](#).

The prompt text is sent to the output callbacks with the [DEBUG_OUTPUT_PROMPT](#) output mask set.

For more information about prompting the user, see [Using Input and Output](#).

IDebugControl4::OutputVaListWide method

The **OutputVaListWide** method formats a string and sends the result to the [output callbacks](#) that are registered with the engine's clients.

Syntax

```
C++
HRESULT OutputVaListWide(
    [in] ULONG Mask,
    [in] PCWSTR Format,
    [in] va_list Args
);
```

Parameters

Mask [in]

Specifies the output-type bit field. See [DEBUG_OUTPUT_XXX](#) for possible values.

Format [in]

Specifies the format string, as in **printf**. Typically, conversion characters work exactly as they do in C. For the floating-point conversion characters, the 64-bit argument is interpreted as a 32-bit floating-point number unless the **I** modifier is used.

The **%p** conversion character is supported, but it represents a pointer in a target's address space. It might not have any modifiers, and it uses the debugger's internal address formatting. The following additional conversion characters are supported.

Character	Argument type	Argument	Text printed
%p	ULONG64	Pointer in an address space.	The value of the pointer.
%N	DWORD_PTR (32 or 64 bits, depending on the host's architecture)	Pointer in the host's virtual address space.	The value of the pointer. (This is equivalent to the standard C %p character.)
%I	ULONG64	Any 64-bit value.	The specified value. If this is greater than 0xFFFFFFFF, it is printed as a 64-bit value; otherwise, it is printed as a 32-bit value.
%ma	ULONG64	Address of a NULL-terminated ASCII string in the process's virtual address space.	The specified string.
%mu	ULONG64	Address of a NULL-terminated Unicode string in the process's virtual address space.	The specified string.
%msa	ULONG64	Address of an ANSI_STRING structure in the process's virtual address space.	The specified string.
%msu	ULONG64	Address of a UNICODE_STRING structure in the process's virtual address space.	The specified string.
%oy	ULONG64	Address in the process's virtual address space of an item with symbol information.	String that contains the name of the specified symbol (and displacement, if any).
%oly	ULONG64	Address in the process's virtual address space of an item with symbol information.	String that contains the name of the specified symbol (and displacement, if any), as well as any available source line information.

Args [in]

Specifies additional parameters that represent values to be inserted into the output during formatting. *Args* must be initialized using **va_start**. This method does not call **va_end**.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

When generating very large output strings, it is possible to reach the limits of the debugger engine or of the operating system. For example, some versions of the debugger engine have a 16K character limit for a single output. If you find that very large output is getting truncated, you might need to split your output into multiple requests.

Requirements

Target platform

IDebugControl4::ControlledOutputWide method

The **OutputWide** method formats a string and send the result to [output callbacks](#) that have been registered with the engine's clients.

Syntax

C++

```
HRESULT ControlledOutputWide(
    [in] ULONG Mask,
    [in] ULONG Format,
    [in] PCWSTR ... );
}
```

Parameters

Mask [in]

Specifies the output-type bit field. See [DEBUG_OUTPUT_XXX](#) for possible values.

Format [in]

Specifies the format string, as in **printf**. In general, conversion characters work exactly as in C. For the floating-point conversion characters the 64-bit argument is interpreted as a 32-bit floating-point number unless the **I** modifier is used.

The **%p** conversion character is supported, but it represents a pointer in a target's address space. It cannot have any modifiers and it uses the debugger's internal address formatting. The following additional conversion characters are supported.

Character	Argument type	Argument	Text printed
%p	ULONG64	Pointer in an address space	The value of the pointer.
%N	DWORD_PTR (32 or 64 bits, depending on the host's architecture)	Pointer in the host's virtual address space	The value of the pointer. (This is equivalent to the standard C %p character.)
%I	ULONG64	Any 64-bit value	The specified value. If this is greater than 0xFFFFFFFF, it is printed as a 64-bit value. Otherwise, it is printed as a 32-bit value.
%ma	ULONG64	Address of a NULL-terminated ASCII string in the process's virtual address space	The specified string.
%mu	ULONG64	Address of a NULL-terminated Unicode string in the process's virtual address space	The specified string.
%msa	ULONG64	Address of an ANSI_STRING structure in the process's virtual address space	The specified string.
%msu	ULONG64	Address of a UNICODE_STRING structure in the process's virtual address space	The specified string.
%y	ULONG64	Address in the process's virtual address space of an item with symbol information	String that contains the name of the specified symbol (and displacement, if any).
%oly	ULONG64	Address in the process's virtual address space of an item with symbol information	String that contains the name of the specified symbol (and displacement, if any), as well as any available source line information.

... [in]

Specifies additional parameters that contain values to be inserted into the output during formatting.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

When generating very large output strings, it is possible to reach the limits of the debugger engine or of the operating system. For example, some versions of the debugger engine have a 16K character limit for a single output. If you find that very large output is getting truncated, you might need to split your output into multiple requests.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

IDebugControl4::RemoveBreakpoint2 method

The **RemoveBreakpoint2** method removes a breakpoint.

Syntax

C++

```
HRESULT RemoveBreakpoint2(
    [in] PDEBUG_BREAKPOINT2 Bp
);
```

Parameters

Bp [in]

Specifies an interface pointer to breakpoint to remove.

Return value

Return code

Description

S_OK The method was successful.

This method may also return other error values. See [Return Values](#) for more details.

Remarks

After **RemoveBreakpoint** and **RemoveBreakpoint2** are called, the breakpoint object specified in the *Bp* parameter must not be used again.

Note Even though [IDebugBreakpoint](#) extends the COM interface [IUnknown](#), the lifetime of the breakpoint is not controlled using the [IUnknown](#) interface. Instead, the breakpoint is deleted after **RemoveBreakpoint** and **RemoveBreakpoint2** are called.

For more details, see [Using Breakpoints](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugControl4](#)

[IDebugBreakpoint](#)

[AddBreakpoint](#)[Send comments about this topic to Microsoft](#)

IDebugControl4::ReturnInputWide method

The **ReturnInputWide** method is used by **IDebugInputCallbacks** objects to send an input string to the engine following a request for input.

Syntax

```
C++
HRESULT ReturnInputWide(
    [in] PCWSTR Buffer
);
```

Parameters

Buffer [in]

Specifies the input string being sent to the engine.

Return value

Return code	Description
S_OK	The method was successful.
S_FALSE	The engine had already received the input it requested. The input string in <i>Buffer</i> was not received by the engine.

This method may also return error values. See [Return Values](#) for more details.

Remarks

For an overview of input in the debugger engine, see [Input and Output](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugControl4::SetExpressionSyntaxByNameWide method

The **SetExpressionSyntaxByNameWide** method sets the syntax that the engine will use to evaluate expressions.

Syntax

```
C++
HRESULT SetExpressionSyntaxByNameWide(
    [in] PCWSTR AbbrevName
);
```

Parameters

AbbrevName [in]

Specifies the abbreviated name of the syntax. It can be one of the following strings:

C++

Expressions will be evaluated according to C++ syntax. For details of this syntax, see [C++ Numbers and Operators](#).

MASM

Expressions will be evaluated according to MASM syntax. For details of this syntax, see [MASM Numbers and Operators](#).

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

The expression syntax is a global setting within the engine, so setting the expression syntax will affect all clients.

The expression syntax of the engine determines how the engine will interpret expressions passed to [Evaluate](#), [Execute](#), and any other method that evaluates an expression.

After the expression syntax has been changed, the engine sends out notification to the [IDebugEventCallbacks](#) callback object registered with each client. It also passes the DEBUG_CES_EXPRESSION_SYNTAX flag to the [IDebugEventCallbacks::ChangeEngineState](#) method.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugControl4](#)

IDebugControl4::SetEventFilterCommandWide method

The **SetEventFilterCommandWide** method sets a debugger command for the engine to execute when a specified event occurs.

Syntax

C++

```
HRESULT SetEventFilterCommandWide (
    [in] ULONG Index,
    [in] PCWSTR Command
);
```

Parameters

Index [in]

Specifies the index of the event filter. *Index* can take any value between zero and one less than the total number of event filters returned by [GetNumberEventFilters](#) (inclusive). For more information about the index of the filters, see [Index](#) and [Exception Code](#).

Command [in]

Specifies the debugger command for the engine to execute when the event occurs.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

For more information about event filters, see [Event Filters](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugControl4](#)
[sx, sxd, sxe, sxi, sxn \(Set Exceptions\)](#)
[GetEventFilterCommand](#)
[SetExceptionFilterSecondCommand](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugControl4::SetExceptionFilterSecondCommandWide method

The **SetExceptionFilterSecondCommandWide** method sets the command that will be executed by the [debugger engine](#) on the second chance of a specified exception.

Syntax

C++

```
HRESULT SetExceptionFilterSecondCommandWide(
    [in] ULONG Index,
    [in] PCWSTR Command
);
```

Parameters

Index [in]

Specifies the index of the exception filter whose second-chance command will be set. *Index* must not refer to the specific event filters as these are not exception filters and only exception events get a second chance. If *Index* refers to the default exception filter, the second-chance command is set for all exceptions that do not have an exception filter.

Command [in]

Receives the second-chance command for the exception filter.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

For more information about [event filters](#), see [Event Filters](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugControl4](#)

IDebugControl4::SetSpecificFilterArgumentWide method

The **SetSpecificFilterArgumentWide** method sets the value of filter argument for the specific filters that can have an argument.

Syntax

```
C++  
HRESULT SetSpecificFilterArgumentWide(  
    [in] ULONG Index,  
    [in] PCWSTR Argument  
) ;
```

Parameters

Index [in]

Specifies the index of the specific filter whose argument will be set. *Index* must be the index of a specific filter that has an argument.

Argument [in]

Specifies the argument for the specific filter. The interpretation of this argument depends on the specific filter.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
E_INVALIDARG	<i>Index</i> does not refer to a specific filter that has an argument.

Remarks

For a list of specific filters that have argument and the interpretation of those arguments, see [Event Filters](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

IDebugControl4::SetTextMacroWide method

The **SetTextMacroWide** method sets the value of a fixed-name alias.

Syntax

```
C++  
HRESULT SetTextMacroWide(  
    [in] ULONG Slot,  
    [in] PCWSTR Macro  
) ;
```

Parameters

Slot [in]

Specifies the number of the fixed-name alias. *Slot* can take the values 0, 1, ..., 9, that represent the fixed-name aliases **\$u0**, **\$u1**, ..., **\$u9**.

Macro [in]

Specifies the new value of the alias specified by *Slot*. The [debugger engine](#) makes a copy of this string.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

Before executing commands or evaluating expressions, the debugger engine will replace the alias specified by *Slot* with the value of the alias (specified by *Macro*).

For an overview of aliases used by the debugger engine, see [Using Aliases](#). For more information about using aliases with the debugger engine API, see [Interacting with the Engine](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugControl4](#)
[GetTextMacro](#)
[SetTextReplacement](#)
[RemoveTextReplacements](#)
[r \(Registers\)](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugControl4::SetTextReplacementWide method

The **SetTextReplacementWide** method sets the value of a user-named alias.

Syntax

```
C++  
HRESULT SetTextReplacementWide(  
    [in]          PCWSTR SrcText,  
    [in, optional] PCWSTR DstText  
,
```

Parameters

SrcText [in]

Specifies the name of the user-named alias. The [debugger engine](#) makes a copy of this string. If *SrcText* is the same as the name of an automatic alias, the automatic alias is hidden by the new user-named alias.

DstText [in, optional]

Specifies the value of the user-named alias. The debugger engine makes a copy of this string. If *DstText* is **NULL**, the user-named alias is removed.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

Before executing commands or evaluating expressions, the debugger engine will replace the alias specified by *SrcText* with the value of the alias (specified by *DstText*).

If *SrcText* is an asterisk (*) and *DstText* is **NULL**, all user-named aliases are removed. This is the same behavior as the [RemoveTextReplacements](#) method.

When an alias is changed by this method, the event callbacks are notified by passing the DEBUG_CES_TEXT_REPLACEMENTS flag to the [IDebugEventCallbacks::ChangeEngineState](#) callback method.

For an overview of aliases used by the [debugger engine](#), see [Using Aliases](#). For more information about using aliases with the debugger engine API, see [Interacting with the Engine](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

IDebugControl5 interface

Members

The **IDebugControl5** interface inherits from [IDebugControl4](#). **IDebugControl5** also has these types of members:

- [Methods](#)

Methods

The **IDebugControl5** interface has these methods.

Method	Description
GetBreakpointByGuid	The GetBreakpointByGuid method returns the breakpoint with the specified breakpoint GUID.
GetContextStackTraceEx	The GetContextStackTraceEx method returns the frames at the top of the call stack, starting with an arbitrary register context and returning the reconstructed register context for each stack frame. The GetContextStackTraceEx method provides inline frame support. For more information about working with inline functions, see Debugging Optimized Code and Inline Functions .
GetStackTraceEx	The GetStackTraceEx method returns the frames at the top of the specified call stack. The GetStackTraceEx method provides inline frame support. For more information about working with inline functions, see Debugging Optimized Code and Inline Functions .
OutputContextStackTraceEx	The OutputContextStackTraceEx method prints the call stack specified by an array of stack frames and corresponding register contexts. The OutputContextStackTraceEx method provides inline frame support. For more information about working with inline functions, see Debugging Optimized Code and Inline Functions .
OutputStackTraceEx	The OutputStackTraceEx method outputs either the supplied stack frame or the current stack frames. The OutputStackTraceEx method provides inline frame support. For more information about working with inline functions, see Debugging Optimized Code and Inline Functions .

IDebugControl5::GetStackTraceEx method

The GetStackTraceEx method returns the frames at the top of the specified call stack. The GetStackTraceEx method provides inline frame support. For more information about working with inline functions, see [Debugging Optimized Code and Inline Functions](#).

Syntax

C++

```
HRESULT GetStackTraceEx(
    [in]           ULONG64      FrameOffset,
    [in]           ULONG64      StackOffset,
    [in]           ULONG64      InstructionOffset,
    [out]          PDEBUG_STACK_FRAME_EX Frames,
    [in]           ULONG        FrameSize,
    [out, optional] PULONG       FramesFilled
);
```

Parameters*FrameOffset* [in]

Specifies the location of the stack frame at the top of the stack. If *FrameOffset* is set to zero, the current frame pointer is used instead.

StackOffset [in]

Specifies the location of the current stack. If *StackOffset* is set to zero, the current stack pointer is used instead.

InstructionOffset [in]

Specifies the location of the instruction of interest for the function that is represented by the stack frame at the top of the stack. If *InstructionOffset* is set to zero, the current instruction is used instead.

Frames [out]

Receives the stack frames. The number of elements this array holds is *FrameSize*.

FrameSize [in]

Specifies the number of items in the *Frames* array.

FramesFilled [out, optional]

Receives the number of frames that were placed in the array *Frames*. If *FramesFilled* is **NULL**, this information is not returned.

Return value

This method may also return other error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
E_FAIL	No stack frames were returned.

Remarks

The stack trace returned to *Frames* can be printed using [OutputStackTraceEx](#).

IDebugControl5::OutputStackTraceEx method

The OutputStackTraceEx method outputs either the supplied stack frame or the current stack frames. The OutputStackTraceEx method provides inline frame support. For more information about working with inline functions, see [Debugging Optimized Code and Inline Functions](#).

Syntax

```
C++

HRESULT OutputStackTraceEx(
    [in]           ULONG             OutputControl,
    [in, optional] PDEBUG_STACK_FRAME_EX Frames,
    [in]           ULONG             FramesSize,
    [in]           ULONG             Flags
);
```

Parameters

OutputControl [in]

Specifies where to send the output. For possible values, see [DEBUG_OUTCTL_XXX](#).

Frames [in, optional]

Specifies the array of stack frames to output. The number of elements in this array is *FramesSize*. If *Frames* is **NULL**, the current stack frames are used.

FramesSize [in]

Specifies the number of frames to output.

Flags [in]

Specifies bit flags that determine what information to output for each frame. *Flags* can be any combination of values from the following table.

Flag	Description
DEBUG_STACK_ARGUMENTS	Displays the first three pieces of stack memory at the frame of each call. On platforms where parameters are passed on the stack, and the code for the frame uses stack arguments, these values will be the arguments to the function.
DEBUG_STACK_FUNCTION_INFO	Displays information about the function that corresponds to the frame. This includes calling convention and frame pointer omission (FPO) information.
DEBUG_STACK_SOURCE_LINE	Displays source line information for each frame of the stack trace.
DEBUG_STACK_FRAME_ADDRESSES	Displays the return address, previous frame address, and other relevant addresses for each frame.
DEBUG_STACK_COLUMN_NAMES	Displays column names.
DEBUG_STACK_NONVOLATILE_REGISTERS	Displays the non-volatile register context for each frame. This is only meaningful for some platforms.
DEBUG_STACK_FRAME_NUMBERS	Displays frame numbers.
DEBUG_STACK_PARAMETERS	Displays parameter names and values as given in symbol information.
DEBUG_STACK_FRAME_ADDRESSES_RA_ONLY	Displays just the return address in stack frame addresses.
DEBUG_STACK_FRAME_MEMORY_USAGE	Displays the number of bytes that separate the frames.
DEBUG_STACK_PARAMETERS_NEWLINE	Displays each parameter and its type and value on a new line.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

The array of stack frames can be obtained using [GetStackTraceEx](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugControl5](#)
[GetContextStackTraceEx](#)
[GetStackTraceEx](#)
[k, kb, kc, kd, kp, kP, kv \(Display Stack Backtrace\)](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugControl5::GetContextStackTraceEx method

The GetContextStackTraceEx method returns the frames at the top of the call stack, starting with an arbitrary [register context](#) and returning the reconstructed register context for each stack frame. The GetContextStackTraceEx method provides inline frame support. For more information about working with inline functions, see [Debugging Optimized Code and Inline Functions](#).

Syntax

```
C++  
HRESULT GetContextStackTraceEx(  
    [in, optional] PVOID StartContext,  
    [in] ULONG StartContextSize,  
    [out, optional] PDEBUG_STACK_FRAME_EX Frames,  
    [in] ULONG FramesSize,  
    [out, optional] PVOID FrameContexts,  
    [in] ULONG FrameContextsSize,  
    [in] ULONG FrameContextsEntrySize,  
    [out, optional] PULONG FramesFilled  
) ;
```

Parameters

StartContext [in, optional]

Specifies the register context for the top of the stack.

StartContextSize [in]

Specifies the size, in bytes, of the *StartContext* register context.

Frames [out, optional]

Receives the stack frames. The number of elements this array holds is *FrameSize*. If *Frames* is **NULL**, this information is not returned.

FramesSize [in]

Specifies the number of items in the array *Frames*.

FrameContexts [out, optional]

Receives the reconstructed register context for each frame in the stack. The entries in this array correspond to the entries in the *Frames* array. The type of the thread context is the CONTEXT structure for the target's effective processor. If *FrameContexts* is **NULL**, this information is not returned.

FrameContextsSize [in]

Specifies the size, in bytes, of the memory pointed to by *FrameContexts*. The number of stack frames returned equals the number of contexts returned, and *FrameContextsSize* must equal *FramesSize* times *FrameContextsEntrySize*.

FrameContextsEntrySize [in]

Specifies the size, in bytes, of each frame context in *FrameContexts*.

FramesFilled [out, optional]

Receives the number of frames that were placed in the array *Frames* and contexts in *FrameContexts*. If *FramesFilled* is **NULL**, this information is not returned.

Return value

Return code	Description
S_OK	The method was successful.

This method can also return error values. For more information, see [Return Values](#).

Remarks

The stack trace returned to *Frames* and *FrameContexts* can be printed using [OutputContextStackTraceEx](#).

It is common for stack unwinds to restore only a subset of the registers. For example, stack unwinds will not always restore the volatile register state because the volatile registers are scratch registers and code does not need to preserve them. Registers that are not restored on unwind are left as the last value restored, so care should be taken when using the register state that might not be restored by an unwind.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h or Ntddk.h)

See also

IDebugControl5::OutputContextStackTraceEx method

The OutputContextStackTraceEx method prints the call stack specified by an array of stack frames and corresponding register contexts. The OutputContextStackTraceEx method provides inline frame support. For more information about working with inline functions, see [Debugging Optimized Code and Inline Functions](#).

Syntax

```
C++
HRESULT OutputContextStackTraceEx(
    [in] ULONG             OutputControl,
    [in] PDEBUG_STACK_FRAME_EX Frames,
    [in] ULONG             FramesSize,
    [in] PVOID              FrameContexts,
    [in] ULONG             FrameContextsSize,
    [in] ULONG             FrameContextsEntrySize,
    [in] ULONG             Flags
);
```

Parameters

OutputControl [in]

Specifies where to send the output. For possible values, see [DEBUG_OUTCTL_XXX](#).

Frames [in]

Specifies the array of stack frames to output. The number of elements in this array is *FramesSize*. If *Frames* is **NULL**, the current stack frame is used.

FramesSize [in]

Specifies the number of frames to output.

FrameContexts [in]

Specifies the register context for each frame in the stack. The entries in this array correspond to the entries in the *Frames* array. The type of the thread context is the CONTEXT structure for the target's effective processor.

FrameContextsSize [in]

Specifies the size, in bytes, of the memory pointed to by *FrameContexts*. The number of stack frames must equal the number of contexts, and *FrameContextsSize* must equal *FramesSize* multiplied by *FrameContextsEntrySize*.

FrameContextsEntrySize [in]

Specifies the size, in bytes, of each frame context in *FrameContexts*.

Flags [in]

Specifies bit flags that determine what information to output for each frame. *Flags* can be any combination of values from the following table.

Flag	Description
DEBUG_STACK_ARGUMENTS	Displays the first three pieces of stack memory at the frame of each call. On platforms where arguments are passed on the stack, and the code for the frame uses stack arguments, these values will be the arguments to the function.
DEBUG_STACK_FUNCTION_INFO	Displays information about the function that corresponds to the frame. This includes calling convention and frame pointer omission (FPO) information.
DEBUG_STACK_SOURCE_LINE	Displays source line information for each frame of the stack trace.
DEBUG_STACK_FRAME_ADDRESSES	Displays the return address, previous frame address, and other relevant addresses for each frame.
DEBUG_STACK_COLUMN_NAMES	Displays column names.
DEBUG_STACK_NONVOLATILE_REGISTERS	Displays the non-volatile register context for each frame. This is only meaningful for some platforms.
DEBUG_STACK_FRAME_NUMBERS	Displays frame numbers.
DEBUG_STACK_PARAMETERS	Displays parameter names and values as given in symbol information.
DEBUG_STACK_FRAME_ADDRESSES_RA_ONLY	Displays just the return address in the stack frame addresses.
DEBUG_STACK_FRAME_MEMORY_USAGE	Displays the number of bytes that separate the frames.

DEBUG_STACK_PARAMETERS_NEWLINE Displays each parameter and its type and value on a new line.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

IDebugControl5::GetBreakpointByGuid method

The GetBreakpointByGuid method returns the breakpoint with the specified breakpoint GUID.

Syntax

```
C++  
HRESULT GetBreakpointByGuid(  
    [in]     LPGUID           Guid,  
    [out]    PDEBUG_BREAKPOINT3 *Bp  
) ;
```

Parameters

Guid [in]

Specifies the breakpoint GUID of the breakpoint to return.

Bp [out]

Receives the breakpoint.

Return value

This method can also return other error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
E_NOINTERFACE	No breakpoint was found with the given GUID, or the breakpoint with the specified GUID does not belong to the current process, or the breakpoint with the given GUID is private (see GetFlags).

IDebugControl6::GetExecutionStatusEx method

The GetExecutionStatusEx method returns information about the execution status of the [debugger engine](#).

Syntax

```
C++  
HRESULT GetExecutionStatusEx(  
    [out] PULONG Status  
) ;
```

Parameters

Status [out]

Receives the extended execution status. This will be set to values described in [DEBUG STATUS XXX](#).

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

For more information, see [Target Information](#).

See also

IDebugControl6
IDebugControl

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugControl6::GetSynchronizationStatus method

The GetSynchronizationStatus method returns information about the synchronization status of the debugger engine.

Syntax

```
C++  
HRESULT GetSynchronizationStatus(  
    [out] PULONG SendsAttempted,  
    [out] PULONG SecondsSinceLastResponse  
) ;
```

Parameters

SendsAttempted [out]

The number of packet sends that have been attempted by the current debugger-engine kernel transport mechanism. This number will be incremented if engine did not receive a packet "ACK" for the last packet sent by the engine to the target.

SecondsSinceLastResponse [out]

The number of seconds since the last response.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

When the client object connects to a session, the most recent output from the session is sent to the client. If the session is currently waiting on input, the client object is given the opportunity to provide input. Thus, the client object synchronizes with the session's input and output.

IDebugControl7::GetDebuggeeType2 method

The GetDebuggeeType2 method describes the nature of the current target.

Syntax

```
C++
void GetDebuggeeType2(
    [in] ULONG Flags,
    [out] PULONG Class,
    [out] PULONG Qualifier
);
```

Parameters

Flags [in]

Takes a single flag, DEBUG_EXEC_FLAGS_NONBLOCK, that indicates whether the function GetDebuggeeType2 should own the engine critical section object (*g_EngineLock*) before finding the debuggee type.

If the Flag is present, then the function will try to own the critical section. If that fails, it will continue without blocking the caller thread.

If the flag is not passed in, then the function will wait for the engine critical section to become available before continuing.

Class [out]

Receives the class of the current target. It will be set to one of the values in the following table.

Value	Description
DEBUG_CLASS_UNINITIALIZED	There is no current target.
DEBUG_CLASS_KERNEL	The current target is a kernel-mode target.
DEBUG_CLASS_USER_WINDOWS	The current target is a user-mode target.

Qualifier [out]

Provides more details about the type of the target. Its interpretation depends on the value of *Class*. When class is DEBUG_CLASS_UNINITIALIZED, *Qualifier* returns zero. The following values are applicable for kernel-mode targets.

Value	Description
DEBUG_KERNEL_CONNECTION	The current target is a live kernel being debugged in the standard way (using a COM port, 1394 bus, or named pipe).
DEBUG_KERNEL_LOCAL	The current target is the local kernel.
DEBUG_KERNEL_EXDI_DRIVER	The current target is a live kernel connected using eXDI drivers.
DEBUG_KERNEL_SMALL_DUMP	The current target is a kernel-mode Small Memory Dump file.
DEBUG_KERNEL_DUMP	The current target is a kernel-mode Kernel Memory Dump file.
DEBUG_KERNEL_FULL_DUMP	The current target is a kernel-mode Complete Memory Dump file.

The following values are applicable for user-mode targets.

Value	Description
DEBUG_USER_WINDOWS_PROCESS	The current target is a user-mode process on the same computer as the debugger engine .
DEBUG_USER_WINDOWS_PROCESS_SERVER	The current target is a user-mode process connected using a process server.
DEBUG_USER_WINDOWS_SMALL_DUMP	The current target is a user-mode Minidump file.
DEBUG_USER_WINDOWS_DUMP	The current target is a Full User-Mode Dump file.

Return value

This method does not return a value.

IDebugDataSpaces interface

Members

The **IDebugDataSpaces** interface inherits from the **IUnknown** interface. **IDebugDataSpaces** also has these types of members:

- [Methods](#)

Methods

The **IDebugDataSpaces** interface has these methods.

Method

[CheckLowMemory](#)[ReadBusData](#)[ReadControl](#)[ReadDebuggerData](#)[ReadIo](#)[ReadMsr](#)[ReadPhysical](#)[ReadPointersVirtual](#)[ReadProcessorSystemData](#)[ReadVirtual](#)[ReadVirtualUncached](#)[SearchVirtual](#)[WriteBusData](#)[WriteControl](#)[WriteIo](#)[WriteMsr](#)[WritePhysical](#)[WritePointersVirtual](#)[WriteVirtual](#)[WriteVirtualUncached](#)

Description

Checks for memory corruption in the low 4 GB of memory.

Reads data from a system bus.

Reads implementation-specific system data.

Returns information about the target that the debugger engine has queried or determined during the current session.

Reads from the system and bus I/O memory.

Reads a specified Model-Specific Register (MSR).

Reads the target's memory from the specified physical address.

Reads pointers from the target's virtual address space.

Returns data about the specified processor.

Reads memory from the target's virtual address space.

Reads memory from the target's virtual address space.

Searches the target's virtual memory for a specified pattern of bytes.

Writes data to a system bus.

Writes implementation-specific system data.

Writes to the system and bus I/O memory.

Writes a value to the specified Model-Specific Register (MSR).

Writes data to the specified physical address in the target's memory.

Writes pointers to the target's virtual address space.

Writes data to the target's virtual address space.

Writes data to the target's virtual address space.

Requirements

Header Dbgeng.h (include Dbgeng.h)

See also

IDebugDataSpaces::CheckLowMemory method

The **CheckLowMemory** method checks for memory corruption in the low 4 GB of memory.

Syntax

C++

```
HRESULT CheckLowMemory();
```

Parameters

This method has no parameters.

Return value

Return code	Description
S_OK	No corruption was found.
FACILITY_NT_BIT Page	Corruption was found on the memory page <i>Page</i> .

This method can also return error values. See [Return Values](#) for more details.

Remarks

This method is only available in [kernel-mode debugging](#), and is only useful when the *kernel* was booted using the **/nolowmem** option.

When the kernel is booted with the **/nolowmem** option, the kernel, drivers, operating system and applications are loaded in memory above 4 GB, while the low 4 GB of memory is filled with a unique pattern. The **CheckLowMemory** method checks this pattern for corruption.

This may be used to verify that a driver behaves well when using physical addresses greater than 32 bits in length. See *Physical Address Extension (PAE)*, **/pae**, and **/nolowmem** in the Windows Driver Kit.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

IDebugDataSpaces::ReadBusData method

The **ReadBusData** method reads data from a system bus.

Syntax

```
C++
HRESULT ReadBusData(
    [in]          ULONG BusDataType,
    [in]          ULONG BusNumber,
    [in]          ULONG SlotNumber,
    [in]          ULONG Offset,
    [out]         PVOID Buffer,
    [in]          ULONG BufferSize,
    [out, optional] PULONG BytesRead
);
```

Parameters

BusDataType [in]

Specifies the bus data type to read from. For details of allowed values see the documentation for the **BUS_DATA_TYPE** enumeration in the Microsoft Windows SDK.

BusNumber [in]

Specifies the system-assigned number of the bus. This is usually zero, unless the system has more than one bus of the same bus data type.

SlotNumber [in]

Specifies the logical slot number on the bus.

Offset [in]

Specifies the offset in the bus data to start reading from.

Buffer [out]

Receives the data from the bus.

BufferSize [in]

Specifies the size in bytes of the buffer *Buffer*. This is the maximum number of bytes that will be returned.

BytesRead [out, optional]

Receives the number of bytes read from the bus. If *BytesRead* is **NULL**, this information is not returned.

Return value

Return code	Description
S_OK	The method was successful.

This method can also return error values. See [Return Values](#) for more details.

Remarks

This method is only available in kernel-mode debugging.

The nature of the data read from the bus is system, bus, and slot dependent.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugDataSpaces::ReadControl method

The **ReadControl** method reads implementation-specific system data.

Syntax

```
C++  
HRESULT ReadControl(  
    [in]          ULONG    Processor,  
    [in]          ULONG64  Offset,  
    [out]         PVOID     Buffer,  
    [in]          ULONG    BufferSize,  
    [out, optional] PULONG   BytesRead  
) ;
```

Parameters

Processor [in]

Specifies the processor whose information is to be read.

Offset [in]

Specifies the offset in the control space of the memory to read.

Buffer [out]

Receives the data read from the control-space memory.

BufferSize [in]

Specifies the size in bytes of the buffer *Buffer*. This is the maximum number of bytes that will be read.

BytesRead [out, optional]

Receives the number of bytes returned in the buffer *Buffer*. If *BytesRead* is **NULL**, this information is not returned.

Return value

Return code	Description
S_OK	The method was successful.

This method can also return error values. See [Return Values](#) for more details.

Remarks

This method is only available in kernel-mode debugging.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugDataSpaces::ReadDebuggerData method

The **ReadDebuggerData** method returns information about the target that the [debugger engine](#) has queried or determined during the current session. The available information includes the locations of certain key target kernel locations, specific status values, and a number of other things.

Syntax

C++

```
HRESULT ReadDebuggerData(
    [in]          ULONG   Index,
    [out]         PVOID   Buffer,
    [in]          ULONG   BufferSize,
    [out, optional] PULONG  DataSize
);
```

Parameters

Index [in]

Specifies the index of the data to retrieve. The following values are valid:

Value	Return Type	Description
DEBUG_DATA_KernBase	ULONG64	Returns the base address of the kernel image.
DEBUG_DATA_BreakpointWithStatusAddr	ULONG64	Returns the address of the kernel function BreakpointWithStatusInstruction .
DEBUG_DATA_SavedContextAddr	ULONG64	Returns the address of saved context record during a bugcheck. It is only valid after a bugcheck.
DEBUG_DATA_KiCallUserModeAddr	ULONG64	Returns the address of the kernel function KiCallUserMode .
DEBUG_DATA_KeUserCallbackDispatcherAddr	ULONG64	Returns the kernel variable KeUserCallbackDispatcher .
DEBUG_DATA_PsLoadedModuleListAddr	ULONG64	Returns the address of the kernel variable PsLoadedModuleList .
DEBUG_DATA_PsActiveProcessHeadAddr	ULONG64	Returns the address of the kernel variable PsActiveProcessHead .
DEBUG_DATA_PspCidTableAddr	ULONG64	Returns the address of the kernel variable PspCidTable .
DEBUG_DATA_ExSystemResourcesListAddr	ULONG64	Returns the address of the kernel variable ExpSystemResourcesList .
DEBUG_DATA_ExPagedPoolDescriptorAddr	ULONG64	Returns the address of the kernel variable ExpPagedPoolDescriptor .
DEBUG_DATA_ExNumberOfPagedPoolsAddr	ULONG64	Returns the address of the kernel variable ExpNumberOfPagedPools .
DEBUG_DATA_KeTimeIncrementAddr	ULONG64	Returns the address of the kernel variable KeTimeIncrement .
DEBUG_DATA_KeBugCheckCallbackListHeadAddr	ULONG64	Returns the address of the kernel variable KeBugCheckCallbackListHead .
DEBUG_DATA_KiBugCheckDataAddr	ULONG64	Returns the kernel variable KiBugCheckData .
DEBUG_DATA_IopErrorLogListHeadAddr	ULONG64	Returns the address of the kernel variable IopErrorLogListHead .
DEBUG_DATA_ObpRootDirectoryObjectAddr	ULONG64	Returns the address of the kernel variable ObpRootDirectoryObject .
DEBUG_DATA_ObpTypeObjectTypeAddr	ULONG64	Returns the address of the kernel variable ObpTypeObjectType .
DEBUG_DATA_MmSystemCacheStartAddr	ULONG64	Returns the address of the kernel variable MmSystemCacheStart .
DEBUG_DATA_MmSystemCacheEndAddr	ULONG64	Returns the address of the kernel variable MmSystemCacheEnd .
DEBUG_DATA_MmSystemCacheWsAddr	ULONG64	Returns the address of the kernel variable MmSystemCacheWs .
DEBUG_DATA_MmPfnDatabaseAddr	ULONG64	Returns the address of the kernel variable MmPfnDatabase .
DEBUG_DATA_MmSystemPtesStartAddr	ULONG64	Returns the kernel variable MmSystemPtesStart .
DEBUG_DATA_MmSystemPtesEndAddr	ULONG64	Returns the kernel variable MmSystemPtesEnd .
DEBUG_DATA_MmSubsectionBaseAddr	ULONG64	Returns the address of the kernel variable MmSubsectionBase .
DEBUG_DATA_MmNumberOfPagingFilesAddr	ULONG64	Returns the address of the kernel variable MmNumberOfPagingFiles .
DEBUG_DATA_MmLowestPhysicalPageAddr	ULONG64	Returns the address of the kernel variable MmLowestPhysicalPage .
DEBUG_DATA_MmHighestPhysicalPageAddr	ULONG64	Returns the address of the kernel variable MmHighestPhysicalPage .
DEBUG_DATA_MmNumberOfPhysicalPagesAddr	ULONG64	Returns the address of the kernel variable MmNumberOfPhysicalPages .
DEBUG_DATA_MmMaximumNonPagedPoolInBytesAddr	ULONG64	Returns the address of the kernel variable MmMaximumNonPagedPoolInBytes .
DEBUG_DATA_MmNonPagedSystemStartAddr	ULONG64	Returns the address of the kernel variable MmNonPagedSystemStart .
DEBUG_DATA_MmNonPagedPoolStartAddr	ULONG64	Returns the address of the kernel variable MmNonPagedPoolStart .
DEBUG_DATA_MmNonPagedPoolEndAddr	ULONG64	Returns the address of the kernel variable MmNonPagedPoolEnd .
DEBUG_DATA_MmPagedPoolStartAddr	ULONG64	Returns the address of the kernel variable MmPagedPoolStart .
DEBUG_DATA_MmPagedPoolEndAddr	ULONG64	Returns the address of the kernel variable MmPagedPoolEnd .
DEBUG_DATA_MmPagedPoolInformationAddr	ULONG64	Returns the address of the kernel variable MmPagedPoolInfo .
DEBUG_DATA_MmPageSize	ULONG64	Returns the page size.

DEBUG_DATA_MmSizeOfPagedPoolInBytesAddr	ULONG64	Returns the address of the kernel variable MmSizeOfPagedPoolInBytes .
DEBUG_DATA_MmTotalCommitLimitAddr	ULONG64	Returns the address of the kernel variable MmTotalCommitLimit .
DEBUG_DATA_MmTotalCommittedPagesAddr	ULONG64	Returns the address of the kernel variable MmTotalCommittedPages .
DEBUG_DATA_MmSharedCommitAddr	ULONG64	Returns the address of the kernel variable MmSharedCommit .
DEBUG_DATA_MmDriverCommitAddr	ULONG64	Returns the address of the kernel variable MmDriverCommit .
DEBUG_DATA_MmProcessCommitAddr	ULONG64	Returns the address of the kernel variable MmProcessCommit .
DEBUG_DATA_MmPagedPoolCommitAddr	ULONG64	Returns the address of the kernel variable MmPagedPoolCommit .
DEBUG_DATA_MmExtendedCommitAddr	ULONG64	Returns the address of the kernel variable MmExtendedCommit .
DEBUG_DATA_MmZeroedPageListHeadAddr	ULONG64	Returns the address of the kernel variable MmZeroedPageListHead .
DEBUG_DATA_MmFreePageListHeadAddr	ULONG64	Returns the address of the kernel variable MmFreePageListHead .
DEBUG_DATA_MmStandbyPageListHeadAddr	ULONG64	Returns the address of the kernel variable MmStandbyPageListHead .
DEBUG_DATA_MmModifiedPageListHeadAddr	ULONG64	Returns the address of the kernel variable MmModifiedPageListHead .
DEBUG_DATA_MmModifiedNoWritePageListHeadAddr	ULONG64	Returns the address of the kernel variable MmModifiedNoWritePageListHead .
DEBUG_DATA_MmAvailablePagesAddr	ULONG64	Returns the address of the kernel variable MmAvailablePages .
DEBUG_DATA_MmResidentAvailablePagesAddr	ULONG64	Returns the address of the kernel variable MmResidentAvailablePages .
DEBUG_DATA_PoolTrackTableAddr	ULONG64	Returns the address of the kernel variable PoolTrackTable .
DEBUG_DATA_NonPagedPoolDescriptorAddr	ULONG64	Returns the address of the kernel variable NonPagedPoolDescriptor .
DEBUG_DATA_MmHighestUserAddressAddr	ULONG64	Returns the address of the kernel variable MmHighestUserAddress .
DEBUG_DATA_MmSystemRangeStartAddr	ULONG64	Returns the address of the kernel variable MmSystemRangeStart .
DEBUG_DATA_MmUserProbeAddressAddr	ULONG64	Returns the address of the kernel variable MmUserProbeAddress .
DEBUG_DATA_KdPrintCircularBufferAddr	ULONG64	Returns the kernel variable KdPrintDefaultCircularBuffer .
DEBUG_DATA_KdPrintCircularBufferEndAddr	ULONG64	Returns the address of the end of the array KdPrintDefaultCircularBuffer .
DEBUG_DATA_KdPrintWritePointerAddr	ULONG64	Returns the address of the kernel variable KdPrintWritePointer .
DEBUG_DATA_KdPrintRolloverCountAddr	ULONG64	Returns the address of the kernel variable KdPrintRolloverCount .
DEBUG_DATA_MmLoadedUserImageListAddr	ULONG64	Returns the address of the kernel variable MmLoadedUserImageList .
DEBUG_DATA_PaeEnabled	BOOLEAN	Returns TRUE when the target system has PAE enabled.
DEBUG_DATA_SharedUserData	ULONG64	<p>Returns FALSE otherwise.</p> <p>Returns the address in the target of the shared user-mode structure, KUSER_SHARED_DATA. The KUSER_SHARED_DATA structure is defined in ntddk.h (in the Windows Driver Kit) and ntexapi.h (in the Windows SDK).</p>
DEBUG_DATA_ProductType	ULONG	<p>Some of the information contained in this structure is displayed by the debugger extension !kuser.</p> <p>Returns the value of the NtProductType field in the shared user-mode page.</p>
DEBUG_DATA_SuiteMask	ULONG	<p>This value should be interpreted the same way as the wProductType field of the structure OSVERSIONINFOEX, which is documented in the Windows SDK.</p> <p>Returns the value of the SuiteMask field in the shared user-mode page.</p>
DEBUG_DATA_DumpWriterStatus	ULONG	<p>This value should be interpreted the same way as the wSuiteMask field of the structure OSVERSIONINFOEX, which is documented in the Windows SDK.</p> <p>Returns the status of the writer of the dump file. This value is operating system and dump file type specific.</p>

The following values are valid for Windows XP and later versions of Windows:

Value	Return Type	Description
DEBUG_DATA_NtBuildLabAddr	ULONG64	Returns the address of the kernel variable NtBuildLab .
DEBUG_DATA_KiNormalSystemCall	ULONG64	(Itanium only) Returns the address of the kernel function KiNormalSystemCall .
DEBUG_DATA_KiProcessorBlockAddr	ULONG64	Returns the kernel variable KiProcessorBlock .
DEBUG_DATA_MmUnloadedDriversAddr	ULONG64	Returns the address of the kernel variable MmUnloadedDrivers .
DEBUG_DATA_MmLastUnloadedDriverAddr	ULONG64	Returns the address of the kernel variable MmLastUnloadedDriver .
DEBUG_DATA_MmTriageActionTakenAddr	ULONG64	Returns the address of the kernel variable VerifierTriageActionTaken .
DEBUG_DATA_MmSpecialPoolTagAddr	ULONG64	Returns the address of the kernel variable MmSpecialPoolTag .
DEBUG_DATA_KernelVerifierAddr	ULONG64	Returns the address of the kernel variable KernelVerifier .
DEBUG_DATA_MmVerifierDataAddr	ULONG64	Returns the address of the kernel variable MmVerifierData .
DEBUG_DATA_MmAllocatedNonPagedPoolAddr	ULONG64	Returns the address of the kernel variable MmAllocatedNonPagedPool .
DEBUG_DATA_MmPeakCommitmentAddr	ULONG64	Returns the address of the kernel variable MmPeakCommitment .
DEBUG_DATA_MmTotalCommitLimitMaximumAddr	ULONG64	Returns the address of the kernel variable MmTotalCommitLimitMaximum .
DEBUG_DATA_CmNtCSDVersionAddr	ULONG64	Returns the address of the kernel variable CmNtCSDVersion .
DEBUG_DATA_MmPhysicalMemoryBlockAddr	ULONG64	Returns the address of the kernel variable MmPhysicalMemoryBlock .
DEBUG_DATA_MmSessionBase	ULONG64	Returns the address of the kernel variable MmSessionBase .
DEBUG_DATA_MmSessionSize	ULONG64	Returns the address of the kernel variable MmSessionSize .
DEBUG_DATA_MmSystemParentTablePage	ULONG64	(Itanium only) Returns the address of the kernel variable MmSystemParentTablePage .

The following values are valid for Windows Server 2003 and later versions of Windows:

Value	Return	Description
-------	--------	-------------

	Type	
DEBUG_DATA_MmVirtualTranslationBase	ULONG64	Returns the address of the kernel variable MmVirtualTranslationBase .
DEBUG_DATA_OffsetKThreadNextProcessor	USHORT	Returns the offset of the NextProcessor field in the KTHREAD structure.
DEBUG_DATA_OffsetKThreadTeb	USHORT	Returns the offset of the Teb field in the KTHREAD structure.
DEBUG_DATA_OffsetKThreadKernelStack	USHORT	Returns the offset of the KernelStack field in the KTHREAD structure.
DEBUG_DATA_OffsetKThreadInitialStack	USHORT	Returns the offset of the InitialStack field in the KTHREAD structure.
DEBUG_DATA_OffsetKThreadApcProcess	USHORT	Returns the offset of the ApcState.Process field in the KTHREAD structure.
DEBUG_DATA_OffsetKThreadState	USHORT	Returns the offset of the State field in the KTHREAD structure.
DEBUG_DATA_OffsetKThreadBStore	USHORT	(Itanium only) Returns the offset of the InitialBStore field in the KTHREAD structure.
DEBUG_DATA_OffsetKThreadBStoreLimit	USHORT	(Itanium only) Returns the offset of the BStoreLimit field in the KTHREAD structure.
DEBUG_DATA_SizeEProcess	USHORT	Returns the size of the EPROCESS structure.
DEBUG_DATA_OffsetEprocessPeb	USHORT	Returns the offset of the Peb field in the EPROCESS structure.
DEBUG_DATA_OffsetEprocessParentCID	USHORT	Returns the offset of the InheritedFromUniqueProcessId field in the EPROCESS structure.
DEBUG_DATA_OffsetEprocessDirectoryTableBase	USHORT	Returns the offset of the DirectoryTableBase field in the EPROCESS structure.
DEBUG_DATA_SizePrcb	USHORT	Returns the size of the KPRCB structure.
DEBUG_DATA_OffsetPrcbDpcRoutine	USHORT	Returns the offset of the DpcRoutineActive field in the KPRCB structure.
DEBUG_DATA_OffsetPrebCurrentThread	USHORT	Returns the offset of the CurrentThread field in the KPRCB structure.
DEBUG_DATA_OffsetPrebMhz	USHORT	Returns the offset of the MHz field in the KPRCB structure.
DEBUG_DATA_OffsetPrcbCpuType	USHORT	For Itanium processors: Returns the offset of the ProcessorModel field in the KPRCB structure. For all other processors: Returns the offset of the CpuType field in the KPRCB structure.
DEBUG_DATA_OffsetPrebVendorString	USHORT	For Itanium processors: Returns the offset of the ProcessorVendorString field in the KPRCB structure. For all other processors: Returns the offset of the VendorString field in the KPRCB structure.
DEBUG_DATA_OffsetPrcbProcessorState	USHORT	Returns the offset of the ProcessorState.ContextFrame field in the KPRCB structure.
DEBUG_DATA_OffsetPrebNumber	USHORT	Returns the offset of the Number field in the KPRCB structure.
DEBUG_DATA_SizeETHread	USHORT	Returns the size of the ETHREAD structure.
DEBUG_DATA_KdPrintCircularBufferPtrAddr	ULONG64	Returns the address of the kernel variable KdPrintCircularBuffer .
DEBUG_DATA_KdPrintBufferSizeAddr	ULONG64	Returns the address of the kernel variable KdPrintBufferSize .

Buffer [out]

Receives the value of the specified debugger data. The "Return Type" column in the above table specifies the data type that is returned. The data can be accessed by casting *Buffer* to a pointer to that type.

BufferSize [in]

Specifies the size in bytes of the buffer *Buffer*.

DataSize [out, optional]

Receives the number of bytes used in the buffer *Buffer*. If *DataSize* is **NULL**, this information is not returned.

Return value

Return code	Description
S_OK	The method was successful.

This method can also return error values. See [Return Values](#) for more details.

Remarks

Some or all of the values may be unavailable in certain debugging sessions. For example, some of the values are only available for particular versions of the operating system.

For details on the different values returned by **ReadDebuggerData**, see *Microsoft Windows Internals* by David Solomon and Mark Russinovich, the Microsoft Windows SDK, and the Windows Driver Kit (WDK).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

IDebugDataSpaces::ReadIo method

The **ReadIo** method reads from the system and bus I/O memory.

Syntax

```
C++  
HRESULT ReadIo(  
    [in]           ULONG   InterfaceType,  
    [in]           ULONG   BusNumber,  
    [in]           ULONG   AddressSpace,  
    [in]           ULONG64 Offset,  
    [out]          PVOID   Buffer,  
    [in]           ULONG   BufferSize,  
    [out, optional] PULONG BytesRead  
) ;
```

Parameters

InterfaceType [in]

Specifies the interface type of the I/O bus. This parameter may take values in the INTERFACE_TYPE enumeration defined in wdm.h.

BusNumber [in]

Specifies the system-assigned number of the bus. This is usually zero, unless the system has more than one bus of the same interface type.

AddressSpace [in]

This parameter must be equal to one.

Offset [in]

Specifies the I/O address within the address space.

Buffer [out]

Receives the data read from the I/O bus.

BufferSize [in]

Specifies the size in bytes of the buffer *Buffer*. This is the maximum number of bytes that will be read. At present, this must be 1, 2, or 4.

BytesRead [out, optional]

Receives the number of bytes returned read from the I/O bus. If *BytesRead* is **NULL**, this information is not returned.

Return value

Return code	Description
S_OK	The method was successful.

This method can also return error values. See [Return Values](#) for more details.

Remarks

This method is only available in kernel-mode debugging.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugDataSpaces::ReadMsr method

The **ReadMsr** method reads a specified Model-Specific Register (MSR).

Syntax

```
C++  
HRESULT ReadMsr(  
    [in]     ULONG      Msr,  
    [out]    PULONG64   Value  
) ;
```

Parameters

Msr [in]

Specifies the MSR address.

Value [out]

Receives the value of the MSR.

Return value

Return code	Description
S_OK	The method was successful.

This method can also return error values. See [Return Values](#) for more details.

Remarks

This method is only available in kernel-mode debugging.

For details on the addresses and values of MSRs, see the processor documentation.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugDataSpaces::ReadPhysical method

The **ReadPhysical** method reads the target's memory from the specified physical address.

Syntax

```
C++  
HRESULT ReadPhysical(  
    [in]             ULONG64  Offset,  
    [out]            PVOID    Buffer,  
    [in]             ULONG    BufferSize,  
    [out, optional] PULONG   BytesRead  
) ;
```

Parameters

Offset [in]

Specifies the physical address of the memory to read.

Buffer [out]

Receives the memory that is read.

BufferSize [in]

Specifies the size in bytes of the buffer *Buffer*. This is the maximum number of bytes that will be read.

BytesRead [out, optional]

Receives the number of bytes read from the target's memory. If *BytesRead* is **NULL**, this information is not returned.

Return value

Return code	Description
S_OK	The method was successful.

This method can also return error values. See [Return Values](#) for more details.

Remarks

This method is only available in kernel-mode debugging.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugDataSpaces::ReadPointersVirtual method

The **ReadPointersVirtual** method is a convenience method for reading pointers from the target's virtual address space.

Syntax

```
C++
HRESULT ReadPointersVirtual(
    [in]    ULONG    Count,
    [in]    ULONG64  Offset,
    [out]   PULONG64 Ptrs
);
```

Parameters

Count [in]

Specifies the number of pointers to read.

Offset [in]

Specifies the location in the target's virtual address space to start reading the pointers.

Ptrs [out]

Specifies the array to store the pointers. The number of elements this array holds is *Count*.

Return value

Return code	Description
S_OK	All the pointers were read from the target's memory and stored in <i>Ptrs</i> .

This method can also return error values. See [Return Values](#) for more details.

Remarks

This method reads from the memory from the target's virtual address space. The memory is then treated as a list of pointers. Any 32-bit pointers are then sign-extended to 64-bit values.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugDataSpaces::ReadProcessorSystemData method

The **ReadProcessorSystemData** method returns data about the specified processor.

Syntax

C++

```
HRESULT ReadProcessorSystemData(
    [in]          ULONG   Processor,
    [in]          ULONG   Index,
    [out]         PVOID   Buffer,
    [in]          ULONG   BufferSize,
    [out, optional] PULONG  DataSize
);
```

Parameters

Processor [in]

Specifies the processor whose data is to be read.

Index [in]

Specifies the data type to read. The following table contains the valid values. After successful completion, the data returned in the buffer *Buffer* has the type specified by the middle column.

Value	Description
DEBUG_DATA_KPCR_OFFSET	Returns the virtual address of the processor's Processor Control Region (PCR). In this case, the argument <i>Buffer</i> can be considered to have type PULONG64. Returns the virtual address of the processor's Processor Control Block (PRCB).
DEBUG_DATA_KPRCB_OFFSET	In this case, the argument <i>Buffer</i> can be considered to have type PULONG64. Returns the virtual address of the KTHREAD structure for the system thread running on the processor.
DEBUG_DATA_KTHREAD_OFFSET	In this case, the argument <i>Buffer</i> can be considered to have type PULONG64. Returns the virtual address of the base of the paging information owned by the operating system or the processor. The address and the content at the address are processor- and operating-system-dependent.
DEBUG_DATA_BASE_TRANSLATION_VIRTUAL_OFFSET	In this case, the argument <i>Buffer</i> can be considered to have type PULONG64. Returns a description of the processor.
DEBUG_DATA_PROCESSOR_IDENTIFICATION	In this case, the argument <i>Buffer</i> can be considered to have type PDEBUG_PROCESSOR_IDENTIFICATION_ALL . Returns the speed of the processor in MHz. This may not work in a particular session.
DEBUG_DATA_PROCESSOR_SPEED	In this case, the argument <i>Buffer</i> can be considered to have type PULONG.

Buffer [out]

Receives the processor data. Upon successful completion of the method, the contents of this buffer may be accessed by casting *Buffer* to the type specified in the above table.

BufferSize [in]

Specifies the size in bytes of the buffer *Buffer*. This is the maximum number of bytes that will be returned.

DataSize [out, optional]

Receives the size of the data in bytes. If *DataSize* is NULL, this information is not returned.

Return value

Return code	Description
S_OK	The method was successful.

This method can also return error values. See [Return Values](#) for more details.

Remarks

This method is only available in kernel-mode debugging.

For information about the PCR, PRCB, and KTHREAD structures, as well as information about paging tables, see *Microsoft Windows Internals* by David Solomon and Mark Russinovich.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugDataSpaces::ReadVirtual method

The **ReadVirtual** method reads memory from the target's virtual address space.

Syntax

```
C++  
HRESULT ReadVirtual(  
    [in]          ULONG64  Offset,  
    [out]         PVOID     Buffer,  
    [in]          ULONG    BufferSize,  
    [out, optional] PULONG   BytesRead  
) ;
```

Parameters

Offset [in]

Specifies the location in the target's virtual address space to be read.

Buffer [out]

Specifies the buffer to read the memory into.

BufferSize [in]

Specifies the size in bytes of the buffer. This is also the number of bytes being requested.

BytesRead [out, optional]

Receives the number of bytes that were read. If it is set to **NULL**, this information is not returned.

Return value

Return code	Description
S_OK	The method was successful. It is possible that <i>BytesRead</i> is less than <i>BufferSize</i> , but at least one byte of data was returned.

This method can also return error values. See [Return Values](#) for more details.

Remarks

This method fills the buffer with the contents of the memory in the target's virtual address space.

This method may reference a cache of memory data when retrieving data. If the data is volatile, such as memory-mapped hardware state, use [ReadVirtualUncached](#) instead.

When reading memory that contains pointers, these pointers are for the target's virtual address space and not the engine's. For example, if a data structure contained a string, a second call to this method may be needed to read the contents of the string.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

IDebugDataSpaces::ReadVirtualUncached method

The **ReadVirtualUncached** method reads memory from the target's virtual address space.

Syntax

C++

```
HRESULT ReadVirtualUncached(
    [in]           ULONG64 Offset,
    [out]          PVOID   Buffer,
    [in]           ULONG   BufferSize,
    [out, optional] PULONG  BytesRead
);
```

Parameters

Offset [in]

Specifies the location in the target's virtual address space to be read.

Buffer [out]

Specifies the buffer to read the memory into.

BufferSize [in]

Specifies the size in bytes of the buffer. This is also the number of bytes being requested.

BytesRead [out, optional]

Receives the number of bytes that were read. If it is set to **NULL**, this information is not returned.

Return value

Return code	Description
S_OK	The method was successful. It is possible that <i>BytesRead</i> is less than <i>BufferSize</i> , but at least one byte of data is being returned.

This method can also return error values. See [Return Values](#) for more details.

Remarks

This method fills the buffer with the contents of the memory in the target's virtual address space.

This method behaves identically to [ReadVirtual](#), except that it avoids using the virtual memory cache. It is therefore useful for reading inherently volatile virtual memory, such as memory-mapped device areas, without contaminating or invalidating the cache.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

IDebugDataSpaces::SearchVirtual method

The **SearchVirtual** method searches the target's virtual memory for a specified pattern of bytes.

Syntax

```
C++  
HRESULT SearchVirtual(  
    [in]  ULONG64  Offset,  
    [in]  ULONG64  Length,  
    [in]  PVOID    Pattern,  
    [in]  ULONG    PatternSize,  
    [in]  ULONG    PatternGranularity,  
    [out] PULONG64 MatchOffset  
) ;
```

Parameters

Offset [in]

Specifies the location in the target's virtual address space to start searching for the pattern.

Length [in]

Specifies how far to search for the pattern. A successful match requires the entire pattern to be found before *Length* bytes have been examined.

Pattern [in]

Specifies the pattern to search for.

PatternSize [in]

Specifies the size in bytes of the pattern. This must be a multiple of the granularity of the pattern.

PatternGranularity [in]

Specifies the granularity of the pattern. For a successful match the pattern must occur a multiple of this value after the start location.

MatchOffset [out]

Receives the location in the target's virtual address space of the pattern, if it was found.

Return value

This method can also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
HRESULT_FROM_NT(STATUS_NO_MORE_ENTRIES)	After examining <i>Length</i> bytes the pattern was not found.

Remarks

This method searches the target's virtual memory for the first occurrence, subject to granularity, of the pattern entirely contained in the *Length* bytes of the target's memory starting at the location *Offset*.

PatternGranularity can be used to ensure the alignment of the match relative to *Offset*. For example, a value of 0x4 can be used to require alignment to a DWORD. A value of 0x1 can be used to allow the pattern to start anywhere.

For additional options, including the ability to restrict the search to writable memory, see [SearchVirtual2](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugDataSpaces::WriteBusData method

The **WriteBusData** method writes data to a system bus.

Syntax

```
C++  
HRESULT WriteBusData(  
    [in]          ULONG   BusDataType,  
    [in]          ULONG   BusNumber,  
    [in]          ULONG   SlotNumber,  
    [in]          ULONG   Offset,  
    [in]          PVOID   Buffer,  
    [in]          ULONG   BufferSize,  
    [out, optional] PULONG BytesWritten  
) ;
```

Parameters

BusDataType [in]

Specifies the bus data type of the bus to write to. For details of allowed values see the documentation for the **BUS_DATA_TYPE** enumeration in the Microsoft Windows SDK.

BusNumber [in]

Specifies the system-assigned number of the bus. This is usually zero, unless the system has more than one bus of the same bus data type.

SlotNumber [in]

Specifies the logical slot number on the bus.

Offset [in]

Specifies the offset in the bus data to start writing to.

Buffer [in]

Specifies the data to write to the bus.

BufferSize [in]

Specifies the size in bytes of the buffer *Buffer*. This is the maximum number of bytes that will be written.

BytesWritten [out, optional]

Receives the number of bytes written to the bus. If *BytesWritten* is **NULL**, this information is not returned.

Return value

This method can also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

This method is only available in kernel-mode debugging.

The nature of the data read from the bus is system, bus, and slot dependent.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugDataSpaces::WriteControl method

The **WriteControl** method writes implementation-specific system data.

Syntax

```
C++  
HRESULT WriteControl(  
    [in]          ULONG    Processor,  
    [in]          ULONG64  Offset,  
    [in]          PVOID     Buffer,  
    [in]          ULONG    BufferSize,  
    [out, optional] PULONG   BytesWritten  
) ;
```

Parameters

Processor [in]

Specifies the processor whose information is to be written.

Offset [in]

Specifies the offset of the control space of the memory to write.

Buffer [in]

Specifies the data to write to the control-space memory.

BufferSize [in]

Specifies the size in bytes of the buffer *Buffer*. This is the maximum number of bytes that will be written.

BytesWritten [out, optional]

Receives the number of bytes returned in the buffer *Buffer*. If *BytesWritten* is **NULL**, this information is not returned.

Return value

This method can also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

This method is only available in kernel-mode debugging.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugDataSpaces::WriteIo method

The **WriteIo** method writes to the system and bus I/O memory.

Syntax

```
C++

HRESULT WriteIo(
    [in]           ULONG   InterfaceType,
    [in]           ULONG   BusNumber,
    [in]           ULONG   AddressSpace,
    [in]           ULONG64 Offset,
    [in]           PVOID   Buffer,
    [in]           ULONG   BufferSize,
    [out, optional] PULONG BytesWritten
);
```

Parameters

InterfaceType [in]

Specifies the interface type of the I/O bus. This parameter may take values in the INTERFACE_TYPE enumeration defined in wdm.h.

BusNumber [in]

Specifies the system-assigned number of the bus. This is usually zero, unless the system has more than one bus of the same interface type.

AddressSpace [in]

Set to one.

Offset [in]

Specifies the location of the requested data.

Buffer [in]

Specifies the data to write to the I/O bus.

BufferSize [in]

Specifies the size in bytes of the buffer *Buffer*. This is the maximum number of bytes that will be written.

BytesWritten [out, optional]

Receives the number of bytes written to I/O bus. If *BytesWritten* is **NULL**, this information is not returned.

Return value

This method can also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

This method is only available in kernel-mode debugging.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugDataSpaces::WriteMsr method

The **WriteMsr** method writes a value to the specified Model-Specific Register (MSR).

Syntax

```
C++

HRESULT WriteMsr(
```

```
ULONG Msr,  
ULONG64 Value  
) ;
```

Parameters

Msr

Specifies the MSR address.

Value

Specifies the value to write to the MSR.

Return value

Return code	Description
S_OK	The method was successful.

This method can also return error values. See [Return Values](#) for more details.

Remarks

This method is only available in kernel-mode debugging.

For details on the addresses and values of MSRs, see the processor documentation.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugDataSpaces::WritePhysical method

The **WritePhysical** method writes data to the specified physical address in the target's memory.

Syntax

```
C++  
HRESULT WritePhysical(  
    [in]          ULONG64 Offset,  
    [in]          PVOID   Buffer,  
    [in]          ULONG   BufferSize,  
    [out, optional] PULONG BytesWritten  
) ;
```

Parameters

Offset [in]

Specifies the physical address of the memory to write the data to.

Buffer [in]

Specifies the data to write.

BufferSize [in]

Specifies the size in bytes of the buffer *Buffer*. This is the maximum number of bytes that will be written.

BytesWritten [out, optional]

Receives the number of bytes written to the target's memory. If *BytesWritten* is **NULL**, this information is not returned.

Return value

Return code	Description
S_OK	The method was successful.

This method can also return error values. See [Return Values](#) for more details.

Remarks

This method is only available in kernel-mode debugging.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugDataSpaces::WritePointersVirtual method

The **WritePointersVirtual** method is a convenience method for writing pointers to the target's virtual address space.

Syntax

```
C++
HRESULT WritePointersVirtual(
    [in] ULONG    Count,
    [in] ULONG64  Offset,
    [in] PULONG64 Ptrs
);
```

Parameters

Count [in]

Specifies the number of pointers to write.

Offset [in]

Specifies the location in the target's virtual address space at which to start writing the pointers.

Ptrs [in]

Specifies the array of pointers to write. The number of elements in this array is *Count*.

Return value

This method can also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	All the pointers in <i>Ptrs</i> were written to the target's memory.

Remarks

If the target uses 32-bit pointers, this method casts the specified 64-bit values into 32-bit pointers. Then it writes these pointers to the target's memory.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

© 2016 Microsoft. All rights reserved.

IDebugDataSpaces::WriteVirtual method

The **WriteVirtual** method writes data to the target's virtual address space.

Syntax

```
C++  
HRESULT WriteVirtual(  
    [in]          ULONG64  Offset,  
    [in]          PVOID     Buffer,  
    [in]          ULONG     BufferSize,  
    [out, optional] PULONG   BytesWritten  
) ;
```

Parameters

Offset [in]

Specifies the location in the target's virtual address space to be written.

Buffer [in]

Specifies the buffer to write the memory from.

BufferSize [in]

Specifies the size in bytes of the buffer. This is also the number of bytes requested to be written.

BytesWritten [out, optional]

Receives the number of bytes that were written. If it is set to **NULL**, this information is not returned.

Return value

This method can also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was at least partially successful. <i>BytesWritten</i> indicates the number of bytes successfully written, which may be less than <i>BufferSize</i> .

Remarks

This method writes the buffer to the memory in the target's virtual address space.

This method may only write to a cache of memory data when storing data. To avoid caching, use [WriteVirtualUncached](#) instead.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugDataSpaces::WriteVirtualUncached method

The **WriteVirtualUncached** method writes data to the target's virtual address space.

Syntax

```
C++  
HRESULT WriteVirtualUncached(  
    [in]          ULONG64 Offset,  
    [in]          PVOID    Buffer,  
    [in]          ULONG    BufferSize,  
    [out, optional] PULONG  BytesWritten  
) ;
```

Parameters

Offset [in]

Specifies the location in the target's virtual address space to be written.

Buffer [in]

Specifies the buffer to write the memory from.

BufferSize [in]

Specifies the size in bytes of the buffer. This is also the number of bytes requested to be written.

BytesWritten [out, optional]

Receives the number of bytes that were actually written. If it is set to **NULL**, this information is not returned.

Return value

This method can also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was at least partially successful. <i>BytesWritten</i> indicates the number of bytes successfully written, which may be less than <i>BufferSize</i> .

Remarks

This method writes the buffer to the memory in the target's virtual address space.

This method behaves identically to [WriteVirtual](#), except that it avoids using the virtual memory cache. It is therefore useful for reading inherently volatile virtual memory, such as memory-mapped device areas, without contaminating or invalidating the cache.

IDebugDataSpaces2 interface

Members

The **IDebugDataSpaces2** interface inherits from [IDebugDataSpaces](#). **IDebugDataSpaces2** also has these types of members:

- [Methods](#)

Methods

The **IDebugDataSpaces2** interface has these methods.

Method	Description
FillPhysical	Writes a pattern of bytes to the target's physical memory. The pattern is written repeatedly until the specified memory range is filled.
FillVirtual	Writes a pattern of bytes to the target's virtual memory. The pattern is written repeatedly until the specified memory range is filled.
GetVirtualTranslationPhysicalOffsets	Returns the physical addresses of the system paging structures at different levels of the paging hierarchy.
QueryVirtual	Provides information about the specified pages in the target's virtual address space.
ReadHandleData	Retrieves information about a system object specified by a system handle.
VirtualToPhysical	Translates a location in the target's virtual address space into a physical memory address.

Requirements

Header Dbgeng.h (include Dbgeng.h)

IDebugDataSpaces2::FillPhysical method

The **FillPhysical** method writes a pattern of bytes to the target's physical memory. The pattern is written repeatedly until the specified memory range is filled.

Syntax

```
C++  
HRESULT FillPhysical(  
    [in]          ULONG64 Start,  
    [in]          ULONG   Size,  
    [in]          PVOID   Pattern,  
    [in]          ULONG   PatternSize,  
    [out, optional] PULONG Filled  
) ;
```

Parameters

Start [in]

Specifies the location in the target's physical memory at which to start writing the pattern.

Size [in]

Specifies how many bytes to write to the target's memory.

Pattern [in]

Specifies the pattern to write.

PatternSize [in]

Specifies the size in bytes of the pattern.

Filled [out, optional]

Receives the number of bytes written. If it is set to **NULL**, this information isn't returned.

Return value

This method can also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

This method writes the pattern to the target's memory as many times as will fit in *Size* bytes.

If the final copy of the pattern will not completely fit into the memory range, it will only be partially written. This includes the case where the size of the pattern is larger than the value of *Size*, and the extra bytes in the pattern are ignored.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugDataSpaces2](#)

IDebugDataSpaces2::FillVirtual method

The **FillVirtual** method writes a pattern of bytes to the target's virtual memory. The pattern is written repeatedly until the specified memory range is filled.

Syntax

```
C++  
HRESULT FillVirtual(  
    [in]          ULONG64 Start,  
    [in]          ULONG   Size,  
    [in]          PVOID   Pattern,  
    [in]          ULONG   PatternSize,  
    [out, optional] PULONG  Filled  
) ;
```

Parameters

Start [in]

Specifies the location in the target's virtual address space at which to start writing the pattern.

Size [in]

Specifies how many bytes to write to the target's memory.

Pattern [in]

Specifies the memory location of the pattern.

PatternSize [in]

Specifies the size in bytes of the pattern.

Filled [out, optional]

Receives the number of bytes written. If it is set to **NULL**, this information isn't returned.

Return value

This method can also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

This method writes the pattern to the target's memory as many times as will fit in *Size* bytes.

If the final copy of the pattern will not completely fit into the memory range, it will only be partially written. This includes the case where the size of the pattern is larger than

the value of *Size*, and the extra bytes in the pattern are ignored.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugDataSpaces2::GetVirtualTranslationPhysicalOffsets method

The **GetVirtualTranslationPhysicalOffsets** method returns the physical addresses of the system paging structures at different levels of the paging hierarchy.

Syntax

C++

```
HRESULT GetVirtualTranslationPhysicalOffsets(
    [in]           ULONG64 Virtual,
    [out, optional] PULONG64 Offsets,
    [in]           ULONG   OffsetsSize,
    [out, optional] PULONG   Levels
);
```

Parameters

Virtual [in]

Specifies the location in the target's virtual address space to translate.

Offsets [out, optional]

Receives the physical addresses for the system paging structures. If it is set to **NULL**, this information is not returned.

OffsetsSize [in]

Specifies the number of elements the array *Offsets* holds. This is the maximum number of addresses that will be returned.

Levels [out, optional]

Receives the number of levels in the paging hierarchy for the specified address. If this is **NULL**, this information is not returned.

Return value

This method can also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
HRESULT_FROM_NT(STATUS_NO_PAGEFILE)	No physical page containing the specified address could be found.

Remarks

This method is only available in kernel-mode debugging.

Translating a virtual address to a physical address requires Windows to walk down the paging hierarchy. At each level it reads paging information from physical memory. This method returns the offsets for these physical pages. The number of levels in the paging hierarchy may be different for different addresses.

The address at the last level of the hierarchy is the physical address corresponding to the specified virtual address. This is what [VirtualToPhysical](#) would return.

For details on how virtual addresses are translated into physical addresses, see *Microsoft Windows Internals* by David Solomon and Mark Russinovich.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugDataSpaces2::QueryVirtual method

The **QueryVirtual** method provides information about the specified pages in the target's virtual address space.

Syntax

```
C++  
HRESULT QueryVirtual(  
    [in]    ULONG64          Offset,  
    [out]   PMEMORY_BASIC_INFORMATION64 Info  
) ;
```

Parameters

Offset [in]

Specifies the location in the target's virtual address space of the pages whose information is requested.

Info [out]

Receives the information about the memory page.

Return value

This method can also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

This method may not work in all sessions.

This method returns attributes for a range of pages. This range is determined by Windows; it begins at the specified page, and includes all subsequent pages with the same attributes. The size of the range is given by the **RegionSize** field of the structure returned in *Info*.

MEMORY_BASIC_INFORMATION64 appears in the Microsoft Windows SDK header file winnt.h. It is the 64-bit equivalent of MEMORY_BASIC_INFORMATION, which is described in the Windows SDK documentation.

This method behaves in a similar way to the Windows SDK function **VirtualQuery**. See Windows SDK documentation for details.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugDataSpaces2::ReadHandleData method

The **ReadHandleData** method retrieves information about a system object specified by a system handle.

Syntax

C++

```
HRESULT ReadHandleData(  
    [in]    ULONG64          Handle,  
    [in]    ULONG             DataType,  
    [out, optional] PVOID    Buffer,
```

```
[in]           ULONG  BufferSize,
[out, optional] PULONG  DataSize
);
```

Parameters

Handle [in]

Specifies the system handle of the object whose data is requested. See Handles for information about system handles.

DataType [in]

Specifies the data type to return for the system handle. The following table contains the valid values, along with the corresponding return type:

Value	Description
DEBUG_HANDLE_DATA_TYPE_BASIC	Returns basic information about the system object. In this case, the argument <i>Buffer</i> can be considered to have type PDEBUG_HANDLE_DATA_BASIC .
DEBUG_HANDLE_DATA_TYPE_TYPE_NAME	Returns the name of the object type. For example, "Process" or "Thread". In this case, the argument <i>Buffer</i> can be considered to have type PSTR. Returns the name of the object. This includes its location in the object directory.
DEBUG_HANDLE_DATA_TYPE_OBJECT_NAME	In this case, the argument <i>Buffer</i> can be considered to have type PSTR. Returns the number of handles held by the object. This is similar to the field DEBUG_HANDLE_DATA_BASIC.HandleCount .
DEBUG_HANDLE_DATA_TYPE_HANDLE_COUNT	In this case, the argument <i>Buffer</i> can be considered to have type PULONG. Returns the name of the object type.
DEBUG_HANDLE_DATA_TYPE_TYPE_NAME_WIDE	In this case, the argument <i>Buffer</i> can be considered to have type PWSTR. Returns the name of the object.
DEBUG_HANDLE_DATA_TYPE_OBJECT_NAME_WIDE	In this case, the argument <i>Buffer</i> can be considered to have type PWSTR.

Buffer [out, optional]

Receives the object data. Upon successful completion of the method, the contents of this buffer may be accessed by casting *Buffer* to the type specified in the above table.

If *Buffer* is **NULL**, this information is not returned.

BufferSize [in]

Specifies the size in bytes of the buffer *Buffer*. This is the maximum number of bytes that will be returned.

DataSize [out, optional]

Receives the size of the data in bytes. If *DataSize* is **NULL**, this information is not returned.

Return value

Return code	Description
S_OK	The method was successful.

This method can also return error values. See [Return Values](#) for more details.

Remarks

This method is only available in user-mode debugging.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

IDebugDataSpaces2::VirtualToPhysical method

The **VirtualToPhysical** method translates a location in the target's virtual address space into a physical memory address.

Syntax

```
C++  
HRESULT VirtualToPhysical(  
    [in]  ULONG64  Virtual,  
    [out] PULONG64 Physical  
) ;
```

Parameters

Virtual [in]

Specifies the location in the target's virtual address space to translate.

Physical [out]

Receives the physical memory address.

Return value

Return code	Description
S_OK	The method was successful.
HRESULT_FROM_NT(STATUS_NO_PAGEFILE)	No physical page containing the specified address could be found.

This method can also return error values. See [Return Values](#) for more details.

Remarks

This method is only available in kernel-mode debugging.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugDataSpaces3 interface

Members

The IDebugDataSpaces3 interface inherits from [IDebugDataSpaces2](#). IDebugDataSpaces3 also has these types of members:

- [Methods](#)

Methods

The IDebugDataSpaces3 interface has these methods.

Method	Description
EndEnumTagged	Releases the resources used by the specified enumeration.
GetNextTagged	Returns the GUID for the next block of tagged data in the enumeration.
ReadImageNtHeaders	Returns the NT headers for the specified image loaded in the target.
ReadTagged	Reads the tagged data that might be associated with a debugger session.
StartEnumTagged	Initializes a enumeration over the tagged data associated with a debugger session.

Requirements

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugDataSpaces](#)
[IDebugDataSpaces2](#)
[IDebugDataSpaces4](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugDataSpaces3::EndEnumTagged method

The **EndEnumTagged** method releases the resources used by the specified enumeration.

Syntax

```
C++
HRESULT EndEnumTagged(
    [in] ULONG64 Handle
);
```

Parameters

Handle [in]

Specifies the handle identifying the enumeration. This is the handle returned by [StartEnumTagged](#).

Return value

This method can also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

After a handle has been passed to this method it is no longer valid and must not be used again.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugDataSpaces3::GetNextTagged method

The **GetNextTagged** method returns the GUID for the next block of tagged data in the enumeration.

Syntax

```
C++
HRESULT GetNextTagged(
    [in] ULONG64 Handle,
    [out] LPGUID Tag,
    [out] PULONG Size
);
```

Parameters

Handle [in]

Specifies the handle identifying the enumeration. This is the handle returned by [StartEnumTagged](#).

Tag [out]

Receives the GUID identifying the tagged data. The data may be retrieved by passing this GUID to [ReadTagged](#).

Size [out]

Receives the size of the data identified by the GUID *Tag*.

Return value

This method can also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
S_FALSE	There are no more blocks of tagged data available in this enumeration.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugDataSpaces3](#)
[IDebugDataSpaces4](#)
[StartEnumTagged](#)
[ReadTagged](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugDataSpaces3::ReadImageNtHeaders method

The **ReadImageNtHeaders** method returns the NT headers for the specified image loaded in the target.

Syntax

C++

```
HRESULT ReadImageNtHeaders(
    [in]  ULONG64           ImageBase,
    [out] PIMAGE_NT_HEADERS64 Headers
);
```

Parameters

ImageBase [in]

Specifies the location in the target's virtual address space of the image whose NT headers are being requested.

Headers [out]

Receives the NT headers for the specified image.

Return value

Return code	Description
S_OK	The method was successful.
E_INVALIDARG	No NT headers were found for the specified image.

This method can also return error values. See [Return Values](#) for more details.

Remarks

If the image's NT headers are 32-bit, they are automatically converted to 64-bit for consistency. To determine if the headers were originally 32-bit, look at the value of **Headers.OptionalHeader.Magic**. If the value is IMAGE_NT_OPTIONAL_HDR32_MAGIC, the NT headers were originally 32-bit; otherwise the value is IMAGE_NT_OPTIONAL_HDR64_MAGIC, indicating the NT headers were originally 64-bit.

This method will not read ROM headers.

IMAGE_NT_HEADERS64, IMAGE_NT_OPTIONAL_HDR32_MAGIC, and IMAGE_NT_OPTIONAL_HDR64_MAGIC appear in the Microsoft Windows SDK header file winnt.h. IMAGE_NT_HEADERS64 is the 64-bit equivalent of IMAGE_NT_HEADERS, which is described in the Windows SDK documentation.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugDataSpaces3::ReadTagged method

The **ReadTagged** method reads the tagged data that might be associated with a debugger session.

Syntax

```
C++
HRESULT ReadTagged(
    [in]          LPGUID Tag,
    [in]          ULONG  Offset,
    [out, optional] PVOID  Buffer,
    [in]          ULONG  BufferSize,
    [out, optional] PULONG TotalSize
);
```

Parameters

Tag [in]

Specifies the GUID identifying the data requested.

Offset [in]

Specifies the offset within the data to read.

Buffer [out, optional]

Receives the data. If *Buffer* is **NULL**, the data is not returned.

BufferSize [in]

Specifies the size in bytes of the buffer *Buffer*. This is the maximum number of bytes that will be returned.

TotalSize [out, optional]

Receives the total size in bytes of the data specified by *Tag*.

Return value

Return code	Description
S_OK	The method was successful.
E_NOINTERFACE	No data identified by <i>Tag</i> could be found.

This method can also return error values. See [Return Values](#) for more details.

Remarks

Some debugger sessions have arbitrary additional data available. For example, when a dump file is created, additional dump information files containing extra information may also be created. This additional data is tagged with a global unique identifier and can only be retrieved via the tag.

LPGUID is a pointer to a 128-bit unique identifier. It is defined in the Microsoft Windows SDK header file guiddef.h.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugDataSpaces3](#)
[IDebugDataSpaces4](#)
[GetNextTagged](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugDataSpaces3::StartEnumTagged method

The **StartEnumTagged** method initializes a enumeration over the tagged data associated with a debugger session.

Syntax

```
C++  
HRESULT StartEnumTagged(  
    [out] PULONG64 Handle  
) ;
```

Parameters

Handle [out]

Receives the handle identifying the enumeration. This handle can be passed to [GetNextTagged](#) and [EndEnumTagged](#).

Return value

This method can also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

The resources held by an enumeration created with this method can be released using [EndEnumTagged](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugDataSpaces4 interface

Members

The **IDebugDataSpaces4** interface inherits from [IDebugDataSpaces3](#). **IDebugDataSpaces4** also has these types of members:

- [Methods](#)

Methods

The **IDebugDataSpaces4** interface has these methods.

Method	Description
--------	-------------

GetNextDifferentlyValidOffsetVirtual
GetOffsetInformation
GetValidRegionVirtual
ReadMultiByteStringVirtual
ReadMultiByteStringVirtualWide
ReadPhysical2
ReadUnicodeStringVirtual
ReadUnicodeStringVirtualWide
SearchVirtual2
WritePhysical2

Returns the offset of the next address whose validity might be different from the validity of the specified address.
Provides general information about an address in a process's data space.
Locates the first valid region of memory in a specified memory range.
Reads a null-terminated, multibyte string from the target.
Reads a null-terminated, multibyte string from the target and converts it to Unicode.
Reads the target's memory from the specified physical address.
Reads a null-terminated, Unicode string from the target and converts it to a multibyte string.
Reads a null-terminated, Unicode string from the target.
Searches the process's virtual memory for a specified pattern of bytes.
Writes data to the specified physical address in the target's memory.

Requirements

Header Dbgeng.h (include Dbgeng.h)

See also

IDebugDataSpaces
IDebugDataSpaces2
IDebugDataSpaces3

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugDataSpaces4::GetNextDifferentlyValidOffsetVirtual method

The **GetNextDifferentlyValidOffsetVirtual** method returns the offset of the next address whose validity might be different from the validity of the specified address.

Syntax

C++

```
HRESULT GetNextDifferentlyValidOffsetVirtual(
    [in] ULONG64 Offset,
    [out] PULONG64 NextOffset
);
```

Parameters

Offset [in]

Specifies a start address. The address returned in *NextOffset* will be the next address whose validity might be defined differently from this one.

NextOffset [out]

Receives the address of the next address whose validity might be defined differently from the address in *Offset*.

Return value

This method can also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

The size of regions of validity depends on the target. For example, in live user-mode debugging sessions, where virtual address validity changes from page to page, *NextOffset* will receive the address of the next page. In user-mode dump files the validity can change from byte to byte.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugDataSpaces4](#)
[GetValidRegionVirtual](#)

[Send comments about this topic to Microsoft](#)

IDebugDataSpaces4::GetOffsetInformation method

The **GetOffsetInformation** method provides general information about an address in a process's data space.

Syntax

```
C++
HRESULT GetOffsetInformation(
    [in]           ULONG   Space,
    [in]           ULONG   Which,
    [in]           ULONG64 Offset,
    [out, optional] PVOID   Buffer,
    [in]           ULONG   BufferSize,
    [out, optional] PULONG  InfoSize
);
```

Parameters

Space [in]

Specifies the data space to which the *Offset* parameter applies. The allowed values depend on the *Which* parameter.

Which [in]

Specifies which information about the data is being queried. This determines the possible values for *Space* and the type of the data returned in *Buffer*. Possible values are:

DEBUG_OFFSETINFO_VIRTUAL_SOURCE

Returns the source of the target's virtual memory at *Offset*. This is where the debugger engine reads the memory from. *Space* must be set to DEBUG_DATA_SPACE_VIRTUAL. A ULONG is returned to *Buffer*. This ULONG can take the values listed in the following table.

Value	Description
DEBUG_VSOURCE_INVALID	The <i>Offset</i> offset is not available in the process's virtual address space.
DEBUG_VSOURCE_DEBUGGEE	This could mean that the address is invalid, or that the memory is unavailable -- for example, a crash-dump file might not contain all of the memory for the process or for the kernel.
DEBUG_VSOURCE_MAPPED_IMAGE	The virtual memory at the <i>Offset</i> offset is provided by the target. The debugger engine reads the target's virtual memory at <i>Offset</i> offset from a local image file. This is often the case in minidump files where the module images are not included in the dump file and are instead loaded by the debugger engine.

Offset [in]

Specifies the offset in the target's data space for which the information is returned.

Buffer [out, optional]

Specifies the buffer to receive the information. The type of the data returned depends on the value of *Which*. If *Buffer* is NULL, this information is not returned.

BufferSize [in]

Specifies the size, in bytes, of the *Buffer* buffer.

InfoSize [out, optional]

Receives the size, in bytes, of the information that is returned. If *InfoSize* is NULL, this information is not returned.

Return value

This method can also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugDataSpaces4::GetValidRegionVirtual method

The **GetValidRegionVirtual** method locates the first valid region of memory in a specified memory range.

Syntax

```
C++
HRESULT GetValidRegionVirtual(
    [in]  ULONG64 Base,
    [in]  ULONG   Size,
    [out] PULONG64 ValidBase,
    [out] PULONG   ValidSize
);
```

Parameters

Base [in]

Specifies the address of the beginning of the memory range to search for valid memory.

Size [in]

Specifies the size, in bytes, of the memory range to search.

ValidBase [out]

Receives the address of the beginning of the found valid memory.

ValidSize [out]

Receives the size, in bytes, of the valid memory.

Return value

This method can also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugDataSpaces4](#)
[GetNextDifferentlyValidOffsetVirtual](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugDataSpaces4::ReadMultiByteStringVirtual method

The **ReadMultiByteStringVirtual** method reads a null-terminated, multibyte string from the target.

Syntax

```
C++
HRESULT ReadMultiByteStringVirtual(
    [in]           ULONG64 Offset,
    [in]           ULONG   MaxBytes,
    [out, optional] PSTR    Buffer,
    [in]           ULONG   BufferSize,
    [out, optional] PULONG StringBytes
);
```

Parameters

Offset [in]

Specifies the location of the string in the process's virtual address space.

MaxBytes [in]

Specifies the maximum number of bytes to read from the target.

Buffer [out, optional]

Receives the string from the target. If *Buffer* is **NULL**, this information is not returned.

Note The remainder of the buffer, following the returned string, might be overwritten by this method.

BufferSize [in]

Specifies the size, in characters, of the *Buffer* buffer.

StringBytes [out, optional]

Receives the size, in bytes, of the string. If *StringBytes* is **NULL**, this information is not returned.

Return value

Return code	Description
S_OK	The method was successful.
S_FALSE	The method was successful. However <i>Buffer</i> was not large enough to hold the string and the string was truncated to fit in <i>Buffer</i> . The truncated string is null-terminated if <i>Buffer</i> has space for at least one character.
E_INVALIDARG	A null-terminator was not found after reading <i>MaxBytes</i> from the target.

This method can also return error values. See [Return Values](#) for more details.

Remarks

The engine will read up to *MaxBytes* from the target looking for a null-terminator. If the string has more than *BufferSize* characters, the string will be truncated to fit in *Buffer*.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugDataSpaces4](#)
[ReadMultiByteStringVirtualWide](#)
[ReadUnicodeStringVirtual](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugDataSpaces4::ReadMultiByteStringVirtualWide method

The **ReadMultiByteStringVirtualWide** method reads a null-terminated, multibyte string from the target and converts it to Unicode.

Syntax

```
C++
HRESULT ReadMultiByteStringVirtualWide(
    [in]           ULONG64 Offset,
    [in]           ULONG   MaxBytes,
```

```
[in]           ULONG   CodePage,
[in, optional] PWSTR  Buffer,
[in]           ULONG   BufferSize,
[out, optional] PULONG StringBytes
);
```

Parameters

Offset [in]

Specifies the location of the string in the process's virtual address space.

MaxBytes [in]

Specifies the maximum number of bytes to read from the target.

CodePage [in]

Specifies the code page to use to convert the multibyte string read from the target into a Unicode string. For example, CP_ACP is the ANSI code page.

Buffer [out, optional]

Receives the string from the target. If *Buffer* is **NULL**, this information is not returned.

BufferSize [in]

Specifies the size, in characters, of the *Buffer* buffer.

StringBytes [out, optional]

Receives the size, in bytes, of the string in the target. If *StringBytes* is **NULL**, this information is not returned.

Return value

Return code	Description
S_OK	The method was successful.
S_FALSE	The method was not successful.
E_INVALIDARG	A null-terminator was not found after reading <i>MaxBytes</i> from the target.

This method can also return error values. See [Return Values](#) for more details.

Remarks

The engine will read up to *MaxBytes* from the target, looking for a null-terminator. If the string has more than *BufferSize* characters, the string will be truncated to fit in *Buffer*.

Note that even if **S_OK** is returned, the buffer may not have been large enough to store the string. In this case the string is truncated to fit in *Buffer*. The truncated string is null-terminated if *Buffer* has space for at least one character. After the call returns, check to see if **StringBytes* is bigger than *BufferSize*.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h or Winnls.h)

See also

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugDataSpaces4::ReadPhysical2 method

The **ReadPhysical2** method reads the target's memory from the specified physical address.

Syntax

C++

```
HRESULT ReadPhysical2(
    [in]           ULONG64 Offset,
```

```
[in]          ULONG   Flags,
[in]          PVOID   Buffer,
[in]          ULONG   BufferSize,
[out, optional] PULONG  BytesRead
);
```

Parameters

Offset [in]

Specifies the physical address of the memory to read.

Flags [in]

Specifies the properties of the physical memory to be read. This must match the way the physical memory was advertised to the operating system on the target. Possible values are listed in the following table.

Value	Description
DEBUG_PHYSICAL_DEFAULT	Use the default memory caching.
DEBUG_PHYSICAL_CACHED	The physical memory is cached.
DEBUG_PHYSICAL_UNCACHED	The physical memory is uncached.
DEBUG_PHYSICAL_WRITE_COMBINED	The physical memory is write-combined.

Buffer [out]

Receives the memory that is read.

BufferSize [in]

Specifies the size, in bytes, of the *Buffer* buffer. This is the maximum number of bytes that will be read.

BytesRead [out, optional]

Receives the number of bytes read from the target's memory. If *BytesRead* is **NULL**, this information is not returned.

Return value

Return code	Description
S_OK	The method was successful.

This method can also return error values. See [Return Values](#) for more details.

Remarks

This method is only available in kernel-mode debugging.

The flags DEBUG_PHYSICAL_CACHED, DEBUG_PHYSICAL_UNCACHED, and DEBUG_PHYSICAL_WRITE_COMBINED can only be used when the target is a live kernel target that is being debugged in the standard way (using a COM port, 1394 bus, or named pipe).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugDataSpaces4::ReadUnicodeStringVirtual method

The **ReadUnicodeStringVirtual** method reads a null-terminated, Unicode string from the target and converts it to a multibyte string.

Syntax

```
C++
HRESULT ReadUnicodeStringVirtual(
    [in]           ULONG64 Offset,
    [in]           ULONG   MaxBytes,
    [in]           ULONG   CodePage,
    [out, optional] PSTR   Buffer,
    [in]           ULONG   BufferSize,
    [out, optional] PULONG StringBytes
);
```

Parameters

Offset [in]

Specifies the location in the process's virtual address space of the string.

MaxBytes [in]

Specifies the maximum number of bytes to read from the target.

CodePage [in]

Specifies the code page to use to convert the multibyte string read from the target into a Unicode string. For example, CP_ACP is the ANSI code page.

Buffer [out, optional]

Receives the string from the target. If *Buffer* is **NULL**, this information is not returned.

BufferSize [in]

Specifies the size, in characters, of the *Buffer* buffer.

StringBytes [out, optional]

Receives the size, in bytes, of the string in the target. If *StringBytes* is **NULL**, this information is not returned.

Return value

	Return code	Description
S_OK		The method was successful.
S_FALSE		The method was successful. However <i>Buffer</i> was not large enough to hold the string and the string was truncated to fit in <i>Buffer</i> . The truncated string is null-terminated if <i>Buffer</i> has space for at least one character.
E_INVALIDARG		A null-terminator was not found after reading <i>MaxBytes</i> from the target.

This method can also return error values. See [Return Values](#) for more details.

Remarks

The engine will read up to *MaxBytes* from the target, looking for a null-terminator. If the string has more than *BufferSize* characters, the string will be truncated to fit in *Buffer*.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h or Winnls.h)

IDebugDataSpaces4::ReadUnicodeStringVirtualWide method

The **ReadUnicodeStringVirtualWide** method reads a null-terminated, Unicode string from the target.

Syntax

```
C++
HRESULT ReadUnicodeStringVirtualWide(
    [in]           ULONG64 Offset,
    [in]           ULONG   MaxBytes,
    [out, optional] PWSTR   Buffer,
    [in]           ULONG   BufferSize,
    [out, optional] PULONG  StringBytes
);
```

Parameters

Offset [in]

Specifies the location of the string in the process's virtual address space.

MaxBytes [in]

Specifies the maximum number of bytes to read from the target.

Buffer [out, optional]

Receives the string from the target. If *Buffer* is **NULL**, this information is not returned.

Note The remainder of the buffer, following the returned string, might be overwritten by this method.

BufferSize [in]

Specifies the size, in characters, of the *Buffer* buffer.

StringBytes [out, optional]

Receives the size, in bytes, of the string. If *StringBytes* is **NULL**, this information is not returned.

Return value

This method can also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful. However <i>Buffer</i> was not large enough to hold the string and the string was truncated to fit in <i>Buffer</i> . The truncated string is null-terminated if <i>Buffer</i> has space for at least one character.
S_FALSE	A null-terminator was not found after reading <i>MaxBytes</i> from the target.
E_INVALIDARG	

The method was successful.

Remarks

The engine will read up to *MaxBytes* from the target, looking for a null-terminator. If the string has more than *BufferSize* characters, the string will be truncated to fit in *Buffer*.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugDataSpaces4::SearchVirtual2 method

The **SearchVirtual2** method searches the process's virtual memory for a specified pattern of bytes.

Syntax

```
C++
```

```
HRESULT SearchVirtual2(
    [in]    ULONG64    Offset,
    [in]    ULONG64    Length,
    [in]    ULONG      Flags,
    [in]    PVOID       Pattern,
    [in]    ULONG      PatternSize,
    [in]    ULONG      PatternGranularity,
    [out]   PULONG64   MatchOffset
);
```

Parameters

Offset [in]

Specifies the location in the process's virtual address space to start searching for the pattern.

Length [in]

Specifies how far to search for the pattern. A successful match requires the entire pattern to be found before *Length* bytes have been examined.

Flags [in]

Specifies a bit field of flags for the search. Currently, the only bit-flag that can be set is DEBUG_VSEARCH_WRITABLE_ONLY, which restricts the search to writable memory.

Pattern [in]

Specifies the pattern to search for.

PatternSize [in]

Specifies the size, in bytes, of the pattern. This must be a multiple of the granularity of the pattern.

PatternGranularity [in]

Specifies the granularity of the pattern. For a successful match, the difference between the location of the found pattern and *Offset* must be a multiple of *PatternGranularity*.

MatchOffset [out]

Receives the location in the process's virtual address space of the pattern, if it was found.

Return value

This method can also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
HRESULT_FROM_NT(STATUS_NO_MORE_ENTRIES)	After examining <i>Length</i> bytes, the pattern was not found.

Remarks

This method searches the target's virtual memory for the first occurrence, subject to granularity, of the pattern that is entirely contained in the *Length* bytes of the target's memory, starting at the *Offset* location.

PatternGranularity can be used to ensure the alignment of the match relative to *Offset*. For example, a value of 0x4 can be used to require alignment to a DWORD. A value of 0x1 can be used to allow the pattern to start anywhere.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugDataSpaces4::WritePhysical2 method

The **WritePhysical2** method writes data to the specified physical address in the target's memory.

Syntax

```
C++  
HRESULT WritePhysical2(  
    [in]          ULONG64  Offset,  
    [in]          ULONG    Flags,  
    [in]          PVOID    Buffer,  
    [in]          ULONG    BufferSize,  
    [out, optional] PULONG  BytesWritten  
) ;
```

Parameters

Offset [in]

Specifies the physical address of the memory to write the data to.

Flags [in]

Specifies the properties of the physical memory to be written to. This must match the way the physical memory was advertised to the operating system on the target. Possible values are listed in the following table.

Value	Description
DEBUG_PHYSICAL_DEFAULT	Use the default memory caching.
DEBUG_PHYSICAL_CACHED	The physical memory is cached.
DEBUG_PHYSICAL_UNCACHED	The physical memory is uncached.
DEBUG_PHYSICAL_WRITE_COMBINED	The physical memory is write-combined.

Buffer [in]

Specifies the data to write.

BufferSize [in]

Specifies the size, in bytes, of the *Buffer* buffer. This is the maximum number of bytes that will be written.

BytesWritten [out, optional]

Receives the number of bytes written to the target's memory. If *BytesWritten* is **NULL**, this information is not returned.

Return value

This method can also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

This method is only available in kernel-mode debugging.

The flags DEBUG_PHYSICAL_CACHED, DEBUG_PHYSICAL_UNCACHED, and DEBUG_PHYSICAL_WRITE_COMBINED can only be used when the target is a live kernel target that is being debugged in the standard way (using a COM port, 1394 bus, or named pipe).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugRegisters interface

Members

The **IDebugRegisters** interface inherits from the **IUnknown** interface. **IDebugRegisters** also has these types of members:

- [Methods](#)

Methods

The **IDebugRegisters** interface has these methods.

Method	Description
GetDescription	Returns the description of a register.
GetFrameOffset	Returns the location of the stack frame for the current function.
GetIndexByName	Returns the index of the named register.
GetInstructionOffset	Returns the location of the current thread's current instruction.
GetNumberRegisters	Returns the number of registers on the target computer.
GetStackOffset	Returns the current thread's current stack location.
GetValue	Gets the value of one of the target's registers.
GetValues	Gets the value of several of the target's registers.
OutputRegisters	Formats and sends the target's registers to the clients as output.
SetValue	Sets the value of one of the target's registers.
SetValues	Sets the value of several of the target's registers.

Requirements

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugRegisters2](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugRegisters::GetDescription method

The **GetDescription** method returns the description of a register.

Syntax

C++

```
HRESULT GetDescription(
    [in]           ULONG          Register,
    [out, optional] PSTR          NameBuffer,
    [in]           ULONG          NameBufferSize,
    [out, optional] PULONG        NameSize,
    [out, optional] PDEBUG_REGISTER_DESCRIPTION Desc
);
```

Parameters

Register [in]

Specifies the index of the register for which the description is requested.

NameBuffer [out, optional]

Specifies the buffer in which to store the name of the register. If *NameBuffer* is **NULL**, this information is not returned.

NameBufferSize [in]

Specifies the size, in characters, of the buffer that *NameBuffer* specifies.

NameSize [out, optional]

Receives the size, in characters, of the register's name in *NameBuffer* buffer. If *NameSize* is **NULL**, this information is not returned.

Desc [out, optional]

Receives the description of the register. See [DEBUG_REGISTER_DESCRIPTION](#) for more details.

Return value

This list does not contain all the errors that might occur. For a list of possible errors, see [HRESULT Values](#).

Return code	Description
S_OK	The method was successful.
S_FALSE	The method was successful. However, the buffer was not large enough to hold the register's name, so it was truncated.
E_UNEXPECTED	No target machine has been specified, or a description of the register could not be found.
E_INVALIDARG	The index of the register requested is greater than the total number of registers on the target's machine.

Remarks

For an overview of the [IDebugRegisters](#) interface and other register-related methods, see [Registers](#).

Requirements

Target platform

Header Dbgeng.h (include DbgEng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugRegisters::GetFrameOffset method

The **GetFrameOffset** method returns the location of the stack frame for the current function.

Syntax

```
C++
HRESULT GetFrameOffset(
    [out] PULONG64 Offset
);
```

Parameters

Offset [out]

The location in the target's virtual address space of the stack frame for the current function.

Return value

This list does not contain all the errors that might occur. For a list of possible errors, see [HRESULT Values](#).

Return code	Description
S_OK	The method was successful.

Remarks

The meaning of value returned by this method is architecture-specific.

The method [GetFrameOffset2](#) performs the same task as this method but also allows the register source to be specified.

For an overview of the [IDebugRegisters](#) interface and other register-related methods, see [Registers](#).

Requirements

Target platform

Header Dbgeng.h (include DbgEng.h)

See also

[IDebugRegisters](#)
[IDebugRegisters2](#)
[GetFrameOffset2](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugRegisters::GetIndexByName method

The **GetIndexByName** method returns the index of the named register.

Syntax

```
C++  
HRESULT GetIndexByName(  
    [in]  PCSTR Name,  
    [out] PULONG Index  
) ;
```

Parameters

Name [in]

Specifies the name of the register whose index is requested.

Index [out]

Receives the index of the register.

Return value

This list does not contain all the errors that might occur. For a list of possible errors, see [HRESULT Values](#).

Return code	Description
S_OK	The method was successful.
E_NOINTERFACE	The register was not found.

Remarks

For an overview of the [IDebugRegisters](#) interface and other register-related methods, see [Registers](#).

Requirements

Target platform

Header Dbgeng.h (include DbgEng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugRegisters::GetInstructionOffset method

The **GetInstructionOffset** method returns the location of the current thread's current instruction.

Syntax

```
C++  
HRESULT GetInstructionOffset(  
    [out] PULONG64 Offset  
) ;
```

Parameters

Offset [out]

Receives the location in the target's virtual address space of the target's current instruction.

Return value

This list does not contain all the errors that might occur. For a list of possible errors, see [HRESULT Values](#).

Return code	Description
S_OK	The method was successful.

Remarks

The meaning of the value returned by this method is architecture-dependent. In particular, for an Itanium processor, the virtual address returned can indicate an address within a bundle.

The method [GetInstructionOffset2](#) performs the same task as this method but also allows the register source to be specified.

For an overview of the [IDebugRegisters](#) interface and other register-related methods, see [Registers](#).

Requirements

Target platform

Header Dbgeng.h (include DbgEng.h)

See also

[IDebugRegisters](#)
[IDebugRegisters2](#)
[GetInstructionOffset2](#)

IDebugRegisters::GetNumberRegisters method

The **GetNumberRegisters** method returns the number of [registers](#) on the target computer.

Syntax

```
C++
HRESULT GetNumberRegisters(
    [out] PULONG Number
);
```

Parameters

Number [out]

Receives the number of registers on the target's computer.

Return value

This list does not contain all the errors that might occur. For a list of possible errors, see [HRESULT Values](#).

Return code	Description
S_OK	The method was successful.

Remarks

For an overview of the [IDebugRegisters](#) interface and other register-related methods, see [Registers](#).

Requirements

Target platform

Header Dbgeng.h (include DbgEng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugRegisters::GetStackOffset method

The **GetStackOffset** method returns the current thread's current stack location.

Syntax

```
C++  
HRESULT GetStackOffset(  
    [out] PULONG64 Offset  
) ;
```

Parameters

Offset [out]

Receives the location in the process's virtual address space of the current thread's current stack location.

Return value

This list does not contain all the errors that might occur. For a list of possible errors, see [HRESULT Values](#).

Return code	Description
S_OK	The method was successful.

Remarks

The meaning of value returned by this method is architecture specific.

The method [GetStackOffset2](#) performs the same task as this method but also allows the register source to be specified.

For an overview of the [IDebugRegisters](#) interface and other register-related methods, see [Registers](#).

Requirements

Target platform

Header Dbgeng.h (include DbgEng.h)

See also

[IDebugRegisters](#)
[IDebugRegisters2](#)
[GetStackOffset2](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugRegisters::GetValue method

The **GetValue** method gets the value of one of the target's [registers](#).

Syntax

```
C++  
HRESULT GetValue(  
    [in] ULONG Register,  
    [out] PDEBUG_VALUE Value  
) ;
```

Parameters

Register [in]

Specifies the index of the register whose value is requested.

Value [out]

Receives the value of the register. See [DEBUG_VALUE](#) for a description of this parameter type.

Return value

This list does not contain all the errors that might occur. For a list of possible errors, see [HRESULT Values](#).

Return code	Description
S_OK	The method was successful.
E_UNEXPECTED	The target is not accessible, or the register could not be accessed.
E_INVALIDARG	The value of Register is greater than the number of registers on the target machine.

Remarks

To receive the values of multiple registers, use the [GetValues](#) method instead.

For an overview of the [IDebugRegisters](#) interface and other register-related methods, see [Registers](#).

Requirements

Target platform

Header Dbgeng.h (include DbgEng.h)

See also

[IDebugRegisters](#)
[IDebugRegisters2](#)
[GetValues](#)
[GetValues2](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugRegisters::GetValues method

The [GetValues](#) method gets the value of several of the target's [registers](#).

Syntax

```
C++
HRESULT GetValues(
    [in]           ULONG      Count,
    [in, optional] PULONG    Indices,
    [in]           ULONG      Start,
    [out]          PDEBUG_VALUE Values
);
```

Parameters

Count [in]

Specifies the number of registers whose values are requested.

Indices [in, optional]

Specifies an array that contains the indices of the registers from which to get the values. The number of elements in this array is *Count*. If *Indices* is **NULL**, *Start* is used instead.

Start [in]

If *Indices* is **NULL**, the registers will be read consecutively starting at this index. Otherwise it is ignored.

Values [out]

Receives the values of the registers. The number of elements this array holds is *Count*. See [DEBUG_VALUE](#) for a description of this parameter type.

Return value

This list does not contain all the errors that might occur. For a list of possible errors, see [HRESULT Values](#).

Return code	Description
-------------	-------------

S_OK	The method was successful.
E_UNEXPECTED	The target is not accessible, or one of the registers could not be accessed.
E_INVALIDARG	The value of the index of one of the registers is greater than the number of registers on the target machine. Partial results might have been obtained; those registers that could not be read will have the type DEBUG_VALUE_INVALID.

Remarks

`GetValues` gets the value of several of the target's registers.

If the return value is not `S_OK`, some of the registers still might have been read. If the target was not accessible, the return type is `E_UNEXPECTED` and *Values* is unchanged; otherwise, *Values* will contain partial results and the registers that could not be read will have type `DEBUG_VALUE_INVALID`. Ambiguity in the case of the return value `E_UNEXPECTED` can be avoided by setting the memory of *Values* to zero before calling this method.

To receive the value of only a single register, use the [GetValue](#) method instead.

The method [GetValues2](#) performs the same task as this method but also allows the register source to be specified.

For an overview of the [IDebugRegisters](#) interface and other register-related methods, see [Registers](#).

Requirements

Target platform

Header Dbgeng.h (include DbgEng.h)

See also

[IDebugRegisters](#)
[IDebugRegisters2](#)
[GetValue](#)
[GetValues2](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugRegisters::OutputRegisters method

The `OutputRegisters` method formats and sends the target's [registers](#) to the clients as output.

Syntax

```
C++
HRESULT OutputRegisters(
    [in] ULONG OutputControl,
    [in] ULONG Flags
);
```

Parameters

OutputControl [in]

Specifies which clients should be sent the output of the formatted registers. See [DEBUG_OUTCTL_XXX](#) for possible values.

Flags [in]

Specifies which set of registers to print. This can either be `DEBUG_REGISTERS_DEFAULT` to print commonly used registers, `DEBUG_REGISTERS_ALL` to print all the sets of registers, or a combination of the values listed in the following table.

Value	Description
<code>DEBUG_REGISTERS_INT32</code>	Print the 32-bit register set.
<code>DEBUG_REGISTERS_INT64</code>	Print the 64-bit register set.
<code>DEBUG_REGISTERS_FLOAT</code>	Print the floating-point register set.

Return value

This list does not contain all the errors that might occur. For a list of possible errors, see [HRESULT Values](#).

Return code	Description
-------------	-------------

S_OK The method was successful.

Remarks

The registers are formatted in a way that is specific to the target architecture's register set.

The method [OutputRegisters2](#) performs the same task as this method but also allows the register source to be specified.

For an overview of the [IDebugRegisters](#) interface and other register-related methods, see [Registers](#). For details on sending output to the clients, see [Input and Output](#).

Requirements

Target platform

Header Dbgeng.h (include DbgEng.h)

See also

[IDebugRegisters](#)
[IDebugRegisters2](#)
[OutputRegisters2](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugRegisters::SetValue method

The **SetValue** method sets the value of one of the target's [registers](#).

Syntax

```
C++  
HRESULT SetValue(  
    [in] ULONG           Register,  
    [in] PDEBUG_VALUE   Value  
) ;
```

Parameters

Register [in]

Specifies the index of the register whose value is to be set.

Value [in]

Specifies the value to which to set the register. See [DEBUG VALUE](#) for a description of this parameter type.

Return value

This list does not contain all the errors that might occur. For a list of possible errors, see [HRESULT Values](#).

Return code	Description
S_OK	The method was successful.
E_UNEXPECTED	The target is not accessible, or the register could not be accessed.
E_INVALIDARG	The value of <i>Register</i> is greater than the number of registers on the target machine.

Remarks

The engine does its best to coerce the value of *Value* into the type of the register; this coercion is the same as that performed by [CoerceValue](#). If the value is larger than what the register can hold, the least significant bits are dropped. Floating-point and integer conversions will also be performed if necessary.

When a subregister is altered, the register containing it is also altered.

To set the values of multiple registers, use the [SetValues](#) method instead.

For an overview of the [IDebugRegisters](#) interface and other register-related methods, see [Registers](#).

Requirements

Target platform

Header Dbgeng.h (include DbgEng.h)

See also

[IDebugRegisters](#)
[IDebugRegisters2](#)
[SetValues](#)
[SetValues2](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugRegisters::SetValues method

The **SetValues** method sets the value of several of the target's [registers](#).

Syntax

```
C++  
HRESULT SetValues(  
    [in]           ULONG      Count,  
    [in, optional] PULONG     Indices,  
    [in]           ULONG      Start,  
    [in]           PDEBUG_VALUE Values  
) ;
```

Parameters

Count [in]

Specifies the number of registers for which to set the values.

Indices [in, optional]

Specifies an array that contains the indices of the registers for which to set the values. The number of elements in this array is *Count*. If *Indices* is **NULL**, *Start* is used instead.

Start [in]

If *Indices* is **NULL**, the registers will be set consecutively starting at this index. Otherwise it is ignored.

Values [in]

Specifies the array that contains values to which to set the registers. The number of elements this array holds is *Count*. See [DEBUG_VALUE](#) for a description of this parameter type.

Return value

This list does not contain all the errors that might occur. For a list of possible errors, see [HRESULT Values](#).

Return code	Description
S_OK	The method was successful.
E_UNEXPECTED	The target is not accessible, or one or more of the registers could not be accessed.
E_INVALIDARG	The value of the index of one or more of the registers is greater than the number of registers on the target machine.

Remarks

The engine does its best to coerce the values in *Values* into the type of the registers; this coercion is the same as that performed by [CoerceValue](#). If the value is larger than what the register can hold, the least significant bits are dropped. Floating-point and integer conversions will also be performed if necessary.

If the return value is not **S_OK**, some of the registers still might have been set.

When a subregister is altered, the register containing it is also altered.

To set the value of only a single register, use the [SetValue](#) method instead.

The method [SetValues2](#) performs the same task as this method but also allows the register source to be specified.

For an overview of the [IDebugRegisters](#) interface and other register-related methods, see [Registers](#).

IDebugRegisters2 interface

Members

The IDebugRegisters2 interface inherits from [IDebugRegisters](#). IDebugRegisters2 also has these types of members:

- [Methods](#)

Methods

The IDebugRegisters2 interface has these methods.

Method	Description
GetDescriptionWide	Returns the description of a register.
GetFrameOffset2	Returns the location of the stack frame for the current function.
GetIndexByNameWide	Returns the index of the named register.
GetInstructionOffset2	Returns the location of the current thread's current instruction.
GetNumberPseudoRegisters	Returns the number of pseudo-registers that are maintained by the debugger engine.
GetPseudoDescription	Returns a description of a pseudo-register, including its name and type. (ANSI version)
GetPseudoDescriptionWide	Returns a description of a pseudo-register, including its name and type. (Unicode version)
GetPseudoIndexByName	Returns the index of a pseudo-register. (ANSI version)
GetPseudoIndexByNameWide	Returns the index of a pseudo-register. (Unicode version)
GetPseudoValues	Returns the values of a number of pseudo-registers.
GetStackOffset2	Returns the current thread's current stack location.
GetValues2	Fetches the value of several of the target's registers.
OutputRegisters2	Formats and outputs the target's registers.
SetPseudoValues	Sets the value of several pseudo-registers.
SetValues2	Sets the value of several of the target's registers.

Requirements

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugRegisters](#)

[Send comments about this topic to Microsoft](#)

IDebugRegisters2::GetDescriptionWide method

The GetDescriptionWide method returns the description of a register.

Syntax

C++

```

HRESULT GetDescriptionWide(
    [in]           ULONG             Register,
    [out, optional] PWSTR            NameBuffer,
    [in]           ULONG             NameBufferSize,
    [out, optional] PULONG           NameSize,
    [out, optional] PDEBUG_REGISTER_DESCRIPTION Desc
);

```

Parameters

Register [in]

Specifies the index of the register for which the description is requested.

NameBuffer [out, optional]

Specifies the buffer in which to store the name of the register. If *NameBuffer* is **NULL**, this information is not returned.

NameBufferSize [in]

Specifies the size, in characters, of the buffer that *NameBuffer* specifies.

NameSize [out, optional]

Receives the size, in characters, of the register's name in *NameBuffer* buffer. If *NameSize* is **NULL**, this information is not returned.

Desc [out, optional]

Receives the description of the register. See [DEBUG_REGISTER_DESCRIPTION](#) for more details.

Return value

This list does not contain all the errors that might occur. For a list of possible errors, see [HRESULT Values](#).

Return code	Description
S_OK	The method was successful.
S_FALSE	The method was successful. However, the buffer was not large enough to hold the register's name, so it was truncated.
E_UNEXPECTED	No target machine has been specified, or a description of the register could not be found.
E_INVALIDARG	The index of the register requested is greater than the total number of registers on the target's machine.

Remarks

For an overview of the [IDebugRegisters](#) interface and other register-related methods, see [Registers](#).

Requirements

Target platform

Header Dbgeng.h (include DbgEng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugRegisters2::GetFrameOffset2 method

The **GetFrameOffset2** method returns the location of the stack frame for the current function.

Syntax

```

C++
HRESULT GetFrameOffset2(
    [in]   ULONG   Source,
    [out]  PULONG64 Offset
);

```

Parameters

Source [in]

Specifies the register source to query.

The possible values are listed in the following table.

Value	Register source
DEBUG_REGSRC_DEBUGGEE	Fetch register information from the target.
DEBUG_REGSRC_EXPLICIT	Fetch register information from the current explicit register context . Fetch register information from the current scope's register context.
DEBUG_REGSRC_FRAME	Note Stack unwinding does not guarantee accurate updating of the register context, so the scope frame's register context might not be accurate in all cases.

Offset [out]

The location in the process's virtual address space of the stack frame for the current function.

Return value

This list does not contain all the errors that might occur. For a list of possible errors, see [HRESULT Values](#).

Return code	Description
S_OK	The method was successful.

Remarks

The meaning of the value that is returned by this method is architecture-specific.

The method [GetFrameOffset](#) performs the same task as this method but always uses the target as the register source.

For an overview of the [IDebugRegisters](#) interface and other register-related methods, see [Registers](#).

Requirements

Target platform

Header Dbgeng.h (include DbgEng.h)

See also

[IDebugRegisters2](#)
[GetFrameOffset](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugRegisters2::GetIndexByNameWide method

The **GetIndexByNameWide** method returns the index of the named register.

Syntax

```
C++
HRESULT GetIndexByNameWide(
    [in]  PCWSTR Name,
    [out] PULONG Index
);
```

Parameters

Name [in]

Specifies the name of the register whose index is requested.

Index [out]

Receives the index of the register.

Return value

This list does not contain all the errors that might occur. For a list of possible errors, see [HRESULT Values](#).

Return code	Description
S_OK	The method was successful.

S_OK The method was successful.
E_NOINTERFACE The register was not found.

Remarks

For an overview of the [IDebugRegisters](#) interface and other register-related methods, see [Registers](#).

Requirements

Target platform

Header Dbgeng.h (include DbgEng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugRegisters2::GetInstructionOffset2 method

The **GetInstructionOffset2** method returns the location of the current thread's current instruction.

Syntax

C++

```
HRESULT GetInstructionOffset2(
    [in] ULONG   Source,
    [out] PULONG64 Offset
);
```

Parameters

Source [in]

Specifies the register source to query.

The possible values are listed in the following table.

Value	Register source
DEBUG_REGSRC_DEBUGGEE	Fetch register information from the target.
DEBUG_REGSRC_EXPLICIT	Fetch register information from the current explicit register context . Fetch register information from the current scope's register context.
DEBUG_REGSRC_FRAME	Note Stack unwinding does not guarantee accurate updating of the register context, so the scope frame's register context might not be accurate in all cases.

Offset [out]

Receives the location in the process's virtual address space of the current instruction of the current thread.

Return value

This list does not contain all the errors that might occur. For a list of possible errors, see [HRESULT Values](#).

Return code	Description
S_OK	The method was successful.

Remarks

The meaning of the value that is returned by this method is architecture-dependent. In particular, for an Itanium-based processor, the virtual address that is returned can indicate an address within a bundle.

The method [GetInstructionOffset](#) performs the same task as this method but always uses the target as the register source.

For an overview of the [IDebugRegisters](#) interface and other register-related methods, see [Registers](#).

Requirements

Target platform

Header Dbgeng.h (include DbgEng.h)

See also

[IDebugRegisters2](#)
[GetInstructionOffset](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugRegisters2::GetNumberPseudoRegisters method

The **GetNumberPseudoRegisters** method returns the number of pseudo-registers that are maintained by the debugger engine.

Syntax

C++

```
HRESULT GetNumberPseudoRegisters (
    [out] PULONG Number
);
```

Parameters

Number [out]

Receives the number of pseudo-registers that are maintained by the debugger engine.

Return value

This list does not contain all the errors that might occur. For a list of possible errors, see [HRESULT Values](#).

Return code	Description
S_OK	The method was successful.

Remarks

Not all of the pseudo-registers are available in all debugging sessions or at all times in a particular session.

The valid indices for pseudo-registers are between zero and the number of pseudo-registers, minus one.

For an overview of the [IDebugRegisters](#) interface and other register-related methods, see [Registers](#).

Requirements

Target platform

Header Dbgeng.h (include DbgEng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugRegisters2::GetPseudoDescription method

The **GetPseudoDescription** method returns a description of a pseudo-register, including its name and type.

Syntax

C++

```
HRESULT GetPseudoDescription(
    [in]           ULONG      Register,
    [out, optional] PSTR       NameBuffer,
    [in]           ULONG      NameBufferSize,
    [out, optional] PULONG     NameSize,
    [out, optional] PULONG64   TypeModule,
    [out, optional] PULONG     TypeId
```

);

Parameters

Register [in]

Specifies the index of the pseudo-register whose description is requested. The index is always between zero and the number of pseudo-registers (returned by [GetNumberPseudoRegisters](#)) minus one.

NameBuffer [out, optional]

Receives the name of the pseudo-register. If *NameBuffer* is **NULL**, this information is not returned.

NameBufferSize [in]

Specifies the size, in characters, of the buffer that *NameBuffer* specifies.

NameSize [out, optional]

Receives the size in characters of the name of the pseudo-register. If *NameSize* is **NULL**, this information is not returned.

TypeModule [out, optional]

Receives the base address of the module to which the register's type belongs. If the type of the register is not known, zero is returned. If *TypeModule* is **NULL**, no information is returned.

TypeId [out, optional]

Receives the type ID of the type within the module returned in *TypeModule*. If the type ID is not known, zero is returned. If *TypeId* is **NULL**, no information is returned.

Return value

This list does not contain all the errors that might occur. For a list of possible errors, see [HRESULT Values](#).

Return code	Description
S_OK	The method was successful.
E_FAIL	The description for the register was not available

Remarks

Descriptions are not always available for all registers. If a pseudo-register does not have a value - for example, \$eventip will not have a value before an event has occurred - or a type cannot be determined for a pseudo-register, this method will return E_FAIL.

For an overview of the [IDebugRegisters](#) interface and other register-related methods, see [Registers](#).

Requirements

Target platform

Header Dbgeng.h (include DbgEng.h)

IDebugRegisters2::GetPseudoDescriptionWide method

The **GetPseudoDescriptionWide** method returns a description of a pseudo-register, including its name and type.

Syntax

C++

```
HRESULT GetPseudoDescriptionWide(
    [in]          ULONG      Register,
    [out, optional] PWSTR     NameBuffer,
    [in]          ULONG      NameBufferSize,
```

```
[out, optional] PULONG  NameSize,
[out, optional] PULONG64 TypeModule,
[out, optional] PULONG  TypeId
);
```

Parameters

Register [in]

Specifies the index of the pseudo-register whose description is requested. The index is always between zero and the number of pseudo-registers (returned by [GetNumberPseudoRegisters](#)) minus one.

NameBuffer [out, optional]

Receives the name of the pseudo-register. If *NameBuffer* is **NULL**, this information is not returned.

NameBufferSize [in]

Specifies the size, in characters, of the buffer that *NameBuffer* specifies.

NameSize [out, optional]

Receives the size in characters of the name of the pseudo-register. If *NameSize* is **NULL**, this information is not returned.

TypeModule [out, optional]

Receives the base address of the module to which the register's type belongs. If the type of the register is not known, zero is returned. If *TypeModule* is **NULL**, no information is returned.

TypeId [out, optional]

Receives the type ID of the type within the module returned in *TypeModule*. If the type ID is not known, zero is returned. If *TypeId* is **NULL**, no information is returned.

Return value

This list does not contain all the errors that might occur. For a list of possible errors, see [HRESULT Values](#).

Return code	Description
S_OK	The method was successful.
E_FAIL	The description for the register was not available

Remarks

Descriptions are not always available for all registers. If a pseudo-register does not have a value - for example, **\$eventip** will not have a value before an event has occurred - or a type cannot be determined for a pseudo-register, this method will return E_FAIL.

For an overview of the [IDebugRegisters](#) interface and other register-related methods, see [Registers](#).

IDebugRegisters2::GetPseudoIndexByName method

The **GetPseudoIndexByName** method returns the index of a pseudo-register.

Syntax

C++

```
HRESULT GetPseudoIndexByName (
```

```
[in] PCSTR Name,  
[out] PULONG Index  
) ;
```

Parameters

Name [in]

Specifies the name of the pseudo-register whose index is requested. The name includes the leading dollar sign (\$), for example, "\$frame".

Index [out]

Receives the index of the pseudo-register.

Return value

This list does not contain all the errors that might occur. For a list of possible errors, see [HRESULT Values](#).

Return code	Description
S_OK	The method was successful.

Remarks

For the names of all the pseudo-registers, see [Pseudo-Register Syntax](#).

For an overview of the [IDebugRegisters](#) interface and other register-related methods, see [Registers](#).

Requirements

Target platform

Header Dbgeng.h (include DbgEng.h)

See also

IDebugRegisters2::GetPseudoIndexByNameWide method

The `GetPseudoIndexByNameWide` method returns the index of a pseudo-register.

Syntax

```
C++  
HRESULT GetPseudoIndexByNameWide (  
    [in]  PCWSTR Name,  
    [out] PULONG Index  
) ;
```

Parameters

Name [in]

Specifies the name of the pseudo-register whose index is requested. The name includes the leading dollar sign (\$), for example, "\$frame".

Index [out]

Receives the index of the pseudo-register.

Return value

This list does not contain all the errors that might occur. For a list of possible errors, see [HRESULT Values](#).

Return code	Description
S_OK	The method was successful.

Remarks

For the names of all the pseudo-registers, see [Pseudo-Register Syntax](#).

For an overview of the [IDebugRegisters](#) interface and other register-related methods, see [Registers](#).

Requirements

Target platform

Header Dbgeng.h (include DbgEng.h)

See also

IDebugRegisters2::GetPseudoValues method

The **GetPseudoValues** method returns the values of a number of pseudo-registers.

Syntax

```
C++  
HRESULT GetPseudoValues(  
    [in]          ULONG      Source,  
    [in]          ULONG      Count,  
    [in, optional] PULONG    Indices,  
    [in]          ULONG      Start,  
    [out]         PDEBUG_VALUE Values  
) ;
```

Parameters

Source [in]

Specifies the register source to query.

The possible values are listed in the following table.

Value	Register source
DEBUG_REGSRC_DEBUGGEE	Fetch register information from the target.
DEBUG_REGSRC_EXPLICIT	Fetch register information from the current explicit register context . Fetch register information from the current scope's register context.
DEBUG_REGSRC_FRAME	Note Stack unwinding does not guarantee accurate updating of the register context, so the scope frame's register context might not be accurate in all cases.

Count [in]

Specifies the number of pseudo-registers whose values are being requested.

Indices [in, optional]

Specifies an array of indices of pseudo-registers whose values will be returned. The size of *Indices* is *Count*. If *Indices* is **NULL**, *Start* is used to specify the indices instead.

Start [in]

Specifies the index of the first pseudo-register whose value will be returned. The pseudo-registers, with indices between *Start* and *Start* plus *Count* minus one, will be returned. *Start* is only used if *Indices* is **NULL**.

Values [out]

Receives the values of the specified pseudo-registers. The number of elements that this array holds is *Count*. See [DEBUG_VALUE](#) for a description of this parameter type.

Return value

This list does not contain all the errors that might occur. For a list of possible errors, see [HRESULT Values](#).

Return code	Description
S_OK	The method was successful.

Remarks

For an overview of the [IDebugRegisters](#) interface and other register-related methods, see [Registers](#).

Requirements

Target platform

Header Dbgeng.h (include DbgEng.h)

See also

[IDebugRegisters2](#)
[DEBUG_VALUE](#)
[SetPseudoValues](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugRegisters2::GetStackOffset2 method

The **GetStackOffset2** method returns the current thread's current stack location.

Syntax

```
C++
HRESULT GetStackOffset2(
    [in]    ULONG    Source,
    [out]   PULONG64 Offset
);
```

Parameters

Source [in]

Specifies the register source to query.

The possible values are listed in the following table.

Value	Register source
DEBUG_REGSRC_DEBUGGEE	Fetch register information from the target.
DEBUG_REGSRC_EXPLICIT	Fetch register information from the current explicit register context . Fetch register information from the current scope's register context.
DEBUG_REGSRC_FRAME	Note Stack unwinding does not guarantee accurate updating of the register context, so the scope frame's register context might not be accurate in all cases.

Offset [out]

Receives the location in the process's virtual address space of the current thread's current stack.

Return value

This list does not contain all the errors that might occur. For a list of possible errors, see [HRESULT Values](#).

Return code	Description
S_OK	The method was successful.

Requirements

Target platform

Header Dbgeng.h (include DbgEng.h)

See also

[IDebugRegisters2](#)
[GetStackOffset](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugRegisters2::GetValues2 method

The **GetValues2** method fetches the value of several of the target's [registers](#).

Syntax

```
C++

HRESULT GetValues2(
    [in]          ULONG      Source,
    [in]          ULONG      Count,
    [in, optional] PULONG    Indices,
    [in]          ULONG      Start,
    [out]         PDEBUG_VALUE Values
);
```

Parameters

Source [in]

Specifies the register source to query.

The possible values are listed in the following table.

Value	Register source
DEBUG_REGSRC_DEBUGGEE	Fetch register information from the target.
DEBUG_REGSRC_EXPLICIT	Fetch register information from the current explicit register context . Fetch register information from the current scope's register context.
DEBUG_REGSRC_FRAME	Note Stack unwinding does not guarantee accurate updating of the register context, so the scope frame's register context might not be accurate in all cases.

Count [in]

Specifies the number of registers whose values are requested.

Indices [in, optional]

Specifies an array that contains the indices of the registers from which to get the values. The number of elements in this array is *Count*. If *Indices* is **NULL**, *Start* is used instead.

Start [in]

If *Indices* is **NULL**, the registers will be read consecutively starting at this index. Otherwise, it is ignored.

Values [out]

Receives the values of the registers. The number of elements that this array holds is *Count*. See [DEBUG_VALUE](#) for a description of this parameter type.

Return value

This list does not contain all the errors that might occur. For a list of possible errors, see [HRESULT Values](#).

Return code	Description
S_OK	The method was successful.
E_INVALIDARG	The value of the index of one of the registers is greater than the number of registers on the target computer. Partial results might have been obtained; those registers that could not be read will have the type DEBUG_VALUE_INVALID.

Remarks

If the return value is not S_OK, some of the registers still might have been read. If the target was not accessible, the return type is E_UNEXPECTED and *Values* is unchanged. Otherwise, *Values* will contain partial results and the registers that could not be read will have type DEBUG_VALUE_INVALID. Ambiguity in the case of the return value E_UNEXPECTED can be avoided by setting the memory of *Values* to zero before calling this method.

The method [GetValues](#) performs the same task as this method but always uses the target as the register source.

For an overview of the [IDebugRegisters](#) interface and other register-related methods, see [Registers](#).

Requirements

Target platform

Header Dbgeng.h (include DbgEng.h)

See also

[IDebugRegisters2](#)

[GetValue](#)

[GetValues](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugRegisters2::OutputRegisters2 method

The [OutputRegisters2](#) method formats and outputs the target's [registers](#).

Syntax

```
C++  
HRESULT OutputRegisters2(  
    [in] ULONG OutputControl,  
    [in] ULONG Source,  
    [in] ULONG Flags  
) ;
```

Parameters

OutputControl [in]

Specifies which clients should be sent the output of the formatted registers. See [DEBUG_OUTCTL_XXX](#) for possible values.

Source [in]

Specifies the register source to query.

The possible values are listed in the following table.

Value	Register source
DEBUG_REGSRC_DEBUGGEE	Fetch register information from the target.
DEBUG_REGSRC_EXPLICIT	Fetch register information from the current explicit register context . Fetch register information from the current scope's register context.
DEBUG_REGSRC_FRAME	Note Stack unwinding does not guarantee accurate updating of the register context, so the scope frame's register context might not be accurate in all cases.

Flags [in]

Specifies which register sets to print. This can either be DEBUG_REGISTERS_DEFAULT to print commonly used registers, DEBUG_REGISTERS_ALL to print all of the register sets, or a combination of the values listed in the following table.

Value	Description
DEBUG_REGISTERS_INT32	Print the 32-bit register set.
DEBUG_REGISTERS_INT64	Print the 64-bit register set.
DEBUG_REGISTERS_FLOAT	Print the floating-point register set.

Return value

This list does not contain all the errors that might occur. For a list of possible errors, see [HRESULT Values](#).

Return code	Description
S_OK	The method was successful.

Remarks

The registers are formatted in a way that is specific to the target architecture's register set.

The method [OutputRegisters](#) performs the same task as this method but always uses the target as the register source.

For an overview of the [IDebugRegisters](#) interface and other register-related methods, see [Registers](#).

Requirements

Target platform

Header Dbgeng.h (include DbgEng.h)

See also

[IDebugRegisters2](#)
[OutputRegisters](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugRegisters2::SetPseudoValues method

The **SetPseudoValues** method sets the value of several pseudo-registers.

Syntax

```
C++
HRESULT SetPseudoValues(
    [in]          ULONG      Source,
    [in]          ULONG      Count,
    [in, optional] PULONG    Indices,
    [in]          ULONG      Start,
    [in]          PDEBUG_VALUE Values
);
```

Parameters

Source [in]

Specifies the register source to query.

The possible values are listed in the following table.

Value	Register source
DEBUG_REGSRC_DEBUGGEE	Fetch register information from the target.
DEBUG_REGSRC_EXPLICIT	Fetch register information from the current explicit register context . Fetch register information from the current scope's register context.
DEBUG_REGSRC_FRAME	Note Stack unwinding does not guarantee accurate updating of the register context, so the scope frame's register context might not be accurate in all cases.

Count [in]

Specifies the number of pseudo-registers whose values are being set.

Indices [in, optional]

Specifies an array of indices of pseudo-registers. These are the pseudo-registers whose values will be set. The size of *Indices* is *Count*. If *Indices* is **NULL**, *Start* is used to specify the indices instead.

Start [in]

Specifies the index of the first pseudo-register whose value will be set. The pseudo-registers with indices between *Start* and *Start* plus *Count* minus one, will be set. *Start* is only used if *Indices* is **NULL**.

Values [in]

Specifies the new values of the pseudo-registers. The number of elements this array holds is *Count*. See [DEBUG_VALUE](#) for a description of this parameter type.

Return value

This list does not contain all the errors that might occur. For a list of possible errors, see [HRESULT Values](#).

Return code	Description
S_OK	The method was successful.

Remarks

For an overview of the [IDebugRegisters](#) interface and other register-related methods, see [Registers](#).

Requirements**Target platform**

Header Dbgeng.h (include DbgEng.h)

See also

[IDebugRegisters2](#)
[GetPseudoValues](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugRegisters2::SetValues2 method

The **SetValues2** method sets the value of several of the target's [registers](#).

Syntax

```
C++
HRESULT SetValues2(
    [in]          ULONG      Source,
    [in]          ULONG      Count,
    [in, optional] PULONG    Indices,
    [in]          ULONG      Start,
    [in]          PDEBUG_VALUE Values
);
```

Parameters**Source [in]**

Specifies the register source to query.

The possible values are listed in the following table.

Value	Register source
DEBUG_REGSRC_DEBUGGEE	Fetch register information from the target.
DEBUG_REGSRC_EXPLICIT	Fetch register information from the current explicit register context . Fetch register information from the current scope's register context.
DEBUG_REGSRC_FRAME	Note Stack unwinding does not guarantee accurate updating of the register context, so the scope frame's register context might not be accurate in all cases.

Count [in]

Specifies the number of registers for which to set the values.

Indices [in, optional]

Specifies an array that contains the indices of the registers for which to set the values. The number of elements in this array is *Count*. If *Indices* is **NULL**, *Start* is used instead.

Start [in]

If *Indices* is **NULL**, the registers will be set consecutively starting at this index. Otherwise, it is ignored.

Values [in]

An array that contains the values to which to set the registers. The number of elements that this array holds is *Count*. See [DEBUG_VALUE](#) for a description of this parameter type.

Return value

This list does not contain all the errors that might occur. For a list of possible errors, see [HRESULT Values](#).

Return code	Description
S_OK	The method was successful.

Remarks

The engine does its best to cast the values in *Values* into the type of the registers; this conversion is the same as that performed by [CoerceValue](#). If the value is larger than what the register can hold, the least significant bits are dropped. Floating-point and integer conversions will also be performed if necessary.

If the return value is not S_OK, some of the registers still might have been set.

When a subregister is altered, the register that contains it is also altered.

The method [SetValues](#) performs the same task as this method but always uses the target as the register source.

For an overview of the [IDebugRegisters](#) interface and other register-related methods, see [Registers](#).

Requirements

Target platform

Header Dbgeng.h (include DbgEng.h)

See also

[IDebugRegisters2](#)
[SetValue](#)
[SetValues](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugSymbols interface

Members

The **IDebugSymbols** interface inherits from the **IUnknown** interface. **IDebugSymbols** also has these types of members:

- [Methods](#)

Methods

The **IDebugSymbols** interface has these methods.

Method	Description
AddSymbolOptions	Turns on some of the engine's global symbol options.
AppendImagePath	Appends directories to the executable image path.
AppendSourcePath	Appends directories to the source path.
AppendSymbolPath	Appends directories to the symbol path.
CreateSymbolGroup	Creates a new symbol group.
EndSymbolMatch	Releases the resources used by a symbol search.
FindSourceFile	Searches the source path for a specified source file.
GetFieldOffset	Returns the offset of a field from the base address of an instance of a type.
GetImagePath	Returns the executable image path.

GetLineByOffset	Returns the source filename and the line number within the source file of an instruction in the target.
GetModuleByIndex	Returns the location of the module with the specified index.
GetModuleByModuleName	Searches through the target's modules for one with the specified name.
GetModuleByOffset	Searches through the target's modules for one whose memory allocation includes the specified location.
GetModuleNames	Returns the names of the specified module.
GetModuleParameters	Returns parameters for modules in the target.
GetNameByOffset	Returns the name of the symbol at the specified location in the target's virtual address space.
GetNearNameByOffset	Returns the name of a symbol that is located near the specified location.
GetNextSymbolMatch	Returns the next symbol found in a symbol search.
GetNumberModules	Returns the number of modules in the current process's module list.
GetOffsetByLine	Returns the location of the instruction that corresponds to a specified line in the source code.
GetOffsetByName	Returns the location of a symbol identified by name.
GetOffsetTypeId	Returns the type ID of the symbol closest to the specified memory location.
GetScope	Returns information about the current scope.
GetScopeSymbolGroup	Returns a symbol group containing the symbols in the current target's scope.
GetSourceFileLineOffsets	Maps each line in a source file to a location in the target's memory.
GetSourcePath	Returns the source path.
GetSourcePathElement	Returns an element from the source path.
GetSymbolModule	Returns the base address of module which contains the specified symbol.
GetSymbolOptions	Returns the engine's global symbol options.
GetSymbolPath	Returns the symbol path.
GetSymbolTypeId	Returns the type ID and module of the specified symbol.
GetTypeId	Looks up the specified type and return its type ID.
GetType Name	Returns the name of the type symbol specified by its type ID and module.
GetTypeSize	Returns the number of bytes of memory an instance of the specified type requires.
OutputTypedDataPhysical	Formats the contents of a variable in the target computer's physical memory, and then sends this to the output callbacks.
OutputTypedDataVirtual	Formats the contents of a variable in the target's virtual memory, and then sends this to the output callbacks.
ReadTypedDataPhysical	Reads the value of a variable from the target computer's physical memory.
ReadTypedDataVirtual	Reads the value of a variable in the target's virtual memory.
Reload	Deletes the engine's symbol information for the specified module and reload these symbols as needed.
RemoveSymbolOptions	Turns off some of the engine's global symbol options.
ResetScope	Resets the current scope to the default scope of the current thread.
SetImagePath	Sets the executable image path.
SetScope	Sets the current scope.
SetSourcePath	Sets the source path.
SetSymbolOptions	Changes the engine's global symbol options.
SetSymbolPath	Sets the symbol path.
StartSymbolMatch	Initializes a search for symbols whose names match a given pattern.
WriteTypedDataPhysical	Writes the value of a variable in the target computer's physical memory.
WriteTypedDataVirtual	Writes data to the target's virtual address space.

Requirements

Header Dbgeng.h (include Dbgeng.h)

IDebugSymbols::AddSymbolOptions method

The **AddSymbolOptions** method turns on some of the engine's global symbol options.

Syntax

```
C++  
HRESULT AddSymbolOptions(  
    [in] PULONG Options  
) ;
```

Parameters

Options [in]

Specifies the symbol options to turns on. *Options* is a bit-set that will be ORed with the existing symbol options. For a description of the bit flags, see [Setting Symbol Options](#).

Return value

Return code	Description
S_OK	The method was successful.

This method may also return error values. See [Return Values](#) for more details.

Remarks

After the symbol options have been changed, for each client the engine sends out notification to that client's [IDebugEventCallbacks](#) by passing the DEBUG_CES_SYMBOL_OPTIONS flag to the [IDebugEventCallbacks::ChangeSymbolState](#) method.

For more information about symbols, see [Symbols](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h or Dbghelp.h)

See also

[IDebugSymbols](#)

IDebugSymbols::AppendImagePath method

The **AppendImagePath** method appends directories to the executable image path.

Syntax

```
C++  
HRESULT AppendImagePath(  
    [in] PCSTR Addition  
) ;
```

Parameters

Addition [in]

Specifies the directories to append to the executable image path. This is a string that contains directory names separated by semicolons (;).

Return value

Return code	Description
S_OK	The method was successful.

This method may also return error values. See [Return Values](#) for more details.

Remarks

The executable image path is used by the [engine](#) when searching for executable images.

The executable image path can consist of several directories separated by semicolons (;). These directories are searched in order.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

IDebugSymbols::AppendSourcePath method

The **AppendSourcePath** method appends directories to the source path.

Syntax

```
C++  
HRESULT AppendSourcePath(  
    [in] PCSTR Addition  
) ;
```

Parameters

Addition [in]

Specifies the directories to append to the source path. This is a string that contains source path elements separated by semicolons (;). Each source path element can specify either a directory or a source server.

Return value

Return code	Description
S_OK	The method was successful.

This method may also return error values. See [Return Values](#) for more details.

Remarks

The source path is used by the engine when searching for source files.

For more information about manipulating the source path, see [Using Source Files](#). For an overview of the source path and its syntax, see [Source Path](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

IDebugSymbols::AppendSymbolPath method

The **AppendSymbolPath** method appends directories to the symbol path.

Syntax

```
C++  
HRESULT AppendSymbolPath(  
    [in] PCSTR Addition  
) ;
```

Parameters

Addition [in]

Specifies the directories to append to the symbol path. This is a string that contains symbol path elements separated by semicolons (;). Each symbol path element can specify either a directory or a symbol server.

Return value

Return code	Description
S_OK	The method was successful.

This method may also return error values. See [Return Values](#) for more details.

Remarks

For more information about manipulating the symbol path, see [Using Symbols](#). For an overview of the symbol path and its syntax, see [Symbol Path](#).

Requirements

Target platform	
Header	Dbgeng.h (include Dbgeng.h)

See also

IDebugSymbols::CreateSymbolGroup method

The **CreateSymbolGroup** method creates a new symbol group.

Syntax

```
C++  
HRESULT CreateSymbolGroup(  
    [out] IDebugSymbolGroup **Group  
) ;
```

Parameters

Group [out]

Receives an interface pointer for the new [IDebugSymbolGroup](#) object.

Return value

Return code	Description
S_OK	The method was successful.

This method may also return error values. See [Return Values](#) for more details.

Remarks

The newly created symbol group is empty; it does not contain any [symbols](#). Symbols may be added to the symbol group using [IDebugSymbolGroup::AddSymbol](#).

References to the returned object are managed like other COM objects, using the [IUnknown::AddRef](#) and [IUnknown::Release](#) methods. In particular, the [IUnknown::Release](#) method must be called when the returned object is no longer needed. See [Using Client Objects](#) for more information about using COM interfaces in the Debugger Engine API.

For more information about symbol groups, see [Scopes and Symbol Groups](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

IDebugSymbols::EndSymbolMatch method

The [EndSymbolMatch](#) method releases the resources used by a symbol search.

Syntax

C++
HRESULT EndSymbolMatch(
 [in] ULONG64 Handle
)

Parameters

Handle [in]

Specifies the handle returned by [StartSymbolMatch](#) when the search was initialized.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

This method releases the resources held by the engine during a symbol search. After these resources are released, the handle becomes invalid, so it must not be passed to [GetNextSymbolMatch](#) after it has been passed to this method.

For more information about symbols, see [Symbols](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugSymbols](#)

IDebugSymbols::FindSourceFile method

The **FindSourceFile** method searches the source path for a specified source file.

Syntax

C++

```
HRESULT FindSourceFile(
    [in]           ULONG   StartElement,
    [in]           PCSTR   File,
    [in]           ULONG   Flags,
    [out, optional] PULONG  FoundElement,
    [out, optional] PSTR    Buffer,
    [in]           ULONG   BufferSize,
    [out, optional] PULONG  FoundSize
);
```

Parameters

StartElement [in]

Specifies the index of an element within the source path to start searching from. All elements in the source path before *StartElement* are excluded from the search. The index of the first element is zero. If *StartElement* is greater than or equal to the number of elements in the source path, the filing system is checked directly.

This parameter can be used with *FoundElement* to check for multiple matches in the source path.

File [in]

Specifies the path and file name of the file to search for.

Flags [in]

Specifies the search flags. For a description of these flags, see [DEBUG_FIND_SOURCE_XXX](#).

The flag DEBUG_FIND_SOURCE_TOKEN_LOOKUP should not be set. The flag DEBUG_FIND_SOURCE_NO_SRCSRV is ignored because this method does not include source servers in the search.

FoundElement [out, optional]

Receives the index of the element within the source path that contains the file. If the file was found directly on the filing system (not using the source path) then -1 is returned to *FoundElement*. If *FoundElement* is NULL, this information is not returned.

Buffer [out, optional]

Receives the path and name of the found file. If the flag DEBUG_FIND_SOURCE_FULL_PATH is set, this is the full canonical path name for the file. Otherwise, it is the concatenation of the directory in the source path with the tail of *File* that was used to find the file. If *Buffer* is NULL, this information is not returned.

BufferSize [in]

Specifies the size, in characters, of the *Buffer* buffer.

FoundSize [out, optional]

Specifies the size, in characters, of the name of the file. If *FoundSize* is NULL, this information is not returned.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
E_NOINTERFACE	<i>File</i> was not found on the source path.

Remarks

The engine uses the following steps--in order--to search for the file:

1. For each directory in the source path, an attempt is made to find an overlap between the end of the directory path and the beginning of the file path. For example, if the

source path contains a directory C:\a\b\c\d and *File* is c\d\e\samplefile.c, the file C:\a\b\c\d\c\samplefile.c is a match.

If the flag DEBUG_FIND_SOURCE_BEST_MATCH is set, the match with the longest overlap is returned; otherwise, the first match is returned.

2. For each directory in the source path, *File* is appended to the directory. If no match is found, this process is repeated and each time the first directory is removed from the beginning of the file path. For example, if the source path contains a directory C:\a\b and *File* is c\d\c\samplefile.c, then the file C:\a\b\c\samplefile.c is a match.

The first match found is returned.

3. *File* is looked up directly on the filing system.

Note Any source servers in the source path are ignored. To include the source servers in the search, use [FindSourceFileAndToken](#) with a module address specified in *ModAddr*.

For more information about using the source path, see [Using Source Files](#). For an overview of the source path and its syntax, see [Source Path](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugSymbols::GetFieldOffset method

The GetFieldOffset method returns the offset of a field from the base address of an instance of a type.

Syntax

```
C++  
HRESULT GetFieldOffset(  
    [in]  ULONG64 Module,  
    [in]  ULONG   TypeId,  
    [in]  PCSTR   Field,  
    [out] PULONG  Offset  
) ;
```

Parameters

Module [in]

Specifies the module containing the types of both the container and the field.

TypeId [in]

Specifies the type ID of the type containing the field.

Field [in]

Specifies the name of the field whose offset is requested. Subfields may be specified by using a dot-separated path.

Offset [out]

Receives the offset of the specified field from the base memory location of an instance of the type.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
E_NOINTERFACE	The field <i>Field</i> could not be found in the type specified by <i>TypeId</i> .

Remarks

An example of a dot-separated path for the *Field* parameter is as follows. Suppose the MyStruct structure contains a field **MyField** of type MySubStruct, and the MySubStruct structure contains the field **MySubField**. Then the location of this field relative to the location of MyStruct structure can be found by setting the *Field* parameter to "MyField.MySubField".

For more information about types, see [Types](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugSymbols::GetImagePath method

The **GetImagePath** method returns the executable image path.

Syntax

C++

```
HRESULT GetImagePath(
    [out, optional] PSTR    Buffer,
    [in]          ULONG   BufferSize,
    [out, optional] PULONG PathSize
);
```

Parameters

Buffer [out, optional]

Receives the executable image path. This is a string that contains directories separated by semicolons (;). If *Buffer* is **NULL**, this information is not returned.

BufferSize [in]

Specifies the size, in characters, of the *Buffer* buffer.

PathSize [out, optional]

Receives the size, in characters, of the executable image path.

Return value

This method may also return other error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
S_FALSE	The method was successful. However, the buffer was not large enough to hold the executable image path and the path was truncated.

Remarks

The executable image path is used by the engine when searching for executable images.

The executable image path can consist of several directories separated by semicolons. These directories are searched in order.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugSymbols::GetLineByOffset method

The **GetLineByOffset** method returns the source filename and the line number within the source file of an instruction in the target.

Syntax

```
C++  
HRESULT GetLineByOffset(  
    [in]          ULONG64  Offset,  
    [out, optional] PULONG   Line,  
    [out, optional] PSTR     FileBuffer,  
    [in]          ULONG    FileBufferSize,  
    [out, optional] PULONG   FileSize,  
    [out, optional] PULONG64 Displacement  
) ;
```

Parameters

Offset [in]

Specifies the location in the target's virtual address space of the instruction for which to return the source file and line number.

Line [out, optional]

Receives the line number within the source file of the instruction specified by *Offset*. If *Line* is **NULL**, this information is not returned.

FileBuffer [out, optional]

Receives the file name of the file that contains the instruction specified by *Offset*. If *FileBuffer* is **NULL**, this information is not returned.

FileBufferSize [in]

Specifies the size, in characters, of the *FileBuffer* buffer.

FileSize [out, optional]

Specifies the size, in characters, of the source filename. If *FileSize* is **NULL**, this information is not returned.

Displacement [out, optional]

Receives the difference between the location specified in *Offset* and the location of the first instruction of the returned line. If *Displacement* is **NULL**, this information is not returned.

Return value

This method may also return other error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
S_FALSE	The method was successful. However, the buffer was not large enough to hold the name of the source file and the name was truncated.

Remarks

For more information about source files, see [Using Source Files](#).

Requirements

Target platform

IDebugSymbols::GetModuleByIndex method

The **GetModuleByIndex** method returns the location of the module with the specified index.

Syntax

```
C++  
HRESULT GetModuleByIndex(  
    [in]    ULONG    Index,  
    [out]   PULONG64 Base  
) ;
```

Parameters

Index [in]

Specifies the index of the module whose location is requested.

Base [out]

Receives the location in the target's memory address space of the module.

Return value

This method may also return other error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
S_FALSE	The specified module was not loaded, and information about the module was not available.

Remarks

For more information about modules, see [Modules](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugSymbols::GetModuleByName method

The **GetModuleByName** method searches through the target's [modules](#) for one with the specified name.

Syntax

```
C++  
HRESULT GetModuleByName(  
    [in]        PCSTR    Name,  
    [in]        ULONG    StartIndex,  
    [out, optional] PULONG   Index,  
    [out, optional] PULONG64 Base  
) ;
```

Parameters

Name [in]

Specifies the name of the desired module.

StartIndex [in]

Specifies the index to start searching from.

Index [out, optional]

Receives the index of the first module with the name *Name*. If *Index* is **NULL**, this information is not returned.

Base [out, optional]

Receives the location in the target's memory address space of the base of the module. If *Base* is **NULL**, this information is not returned.

Return value

This method may also return other error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
E_INVALIDARG	One of the arguments passed in was invalid.

Remarks

Starting at the specified index, these methods return the first module they find with the specified name. If the target has more than one module with this name, then subsequent modules can be found by repeated calls to these methods with higher values of *StartIndex*.

For more information about modules, see [Modules](#).

Requirements

Target platform

IDebugSymbols::GetModuleByOffset method

The **GetModuleByOffset** method searches through the target's [modules](#) for one whose memory allocation includes the specified location.

Syntax

```
C++  
HRESULT GetModuleByOffset(  
    [in]          ULONG64  Offset,  
    [in]          ULONG    StartIndex,  
    [out, optional] PULONG   Index,  
    [out, optional] PULONG64 Base  
) ;
```

Parameters

Offset [in]

Specifies a location in the target's virtual address space which is inside the desired module's memory allocation -- for example, the address of a symbol belonging to the module.

StartIndex [in]

Specifies the index to start searching from.

Index [out, optional]

Receives the index of the module. If *Index* is **NULL**, this information is not returned.

Base [out, optional]

Receives the location in the target's memory address space of the base of the module. If *Base* is **NULL**, this information is not returned.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

Starting at the specified index, this method returns the first module it finds whose memory allocation address range includes the specified location. If the target has more than one module whose memory address range includes this location, then subsequent modules can be found by repeated calls to this method with higher values of *StartIndex*.

For more information about modules, see [Modules](#).

IDebugSymbols::GetModuleNames method

The **GetModuleNames** method returns the names of the specified module.

Syntax

C++

```
HRESULT GetModuleNames(
    [in]          ULONG     Index,
    [in]          ULONG64   Base,
    [out, optional] PSTR     ImageNameBuffer,
    [in]          ULONG     ImageNameBufferSize,
    [out, optional] PULONG   ImageNameSize,
    [out, optional] PSTR     ModuleNameBuffer,
    [in]          ULONG     ModuleNameBufferSize,
    [out, optional] PULONG   ModuleNameSize,
    [out, optional] PSTR     LoadedImageNameBuffer,
    [in]          ULONG     LoadedImageNameBufferSize,
    [out, optional] PULONG   LoadedImageNameSize
);
```

Parameters

Index [in]

Specifies the index of the module whose names are requested. If it is set to DEBUG_ANY_ID, the module is specified by *Base*.

Base [in]

Specifies the base address of the module whose names are requested. This parameter is only used if *Index* is set to DEBUG_ANY_ID.

ImageNameBuffer [out, optional]

Receives the image name of the module. If *ImageNameBuffer* is **NULL**, this information is not returned.

ImageNameBufferSize [in]

Specifies the size in characters of the buffer *ImageNameBuffer* in characters.

ImageNameSize [out, optional]

Receives the size in characters of the image name. If *ImageNameSize* is **NULL**, this information is not returned.

ModuleNameBuffer [out, optional]

Receives the module name of the module. If *ModuleNameBuffer* is **NULL**, this information is not returned.

ModuleNameBufferSize [in]

Specifies the size in characters of the buffer *ModuleNameBuffer*.

ModuleNameSize [out, optional]

Receives the size in characters of the module name. If *ModuleNameSize* is **NULL**, this information is not returned.

LoadedImageNameBuffer [out, optional]

Receives the loaded image name of the module. If *LoadedImageNameBuffer* is **NULL**, this information is not returned.

LoadedImageNameBufferSize [in]

Specifies the size in characters of the buffer *LoadedImageNameBuffer*.

LoadedImageNameSize [out, optional]

Receives the size in characters of the loaded image name. If *LoadedImageNameSize* is **NULL**, this information is not returned.

Return value

This method may also return other error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
S_FALSE	The method was successful. However, at least one of <i>ImageNameBuffer</i> , <i>ModuleNameBuffer</i> , or <i>LoadedImageNameBuffer</i> was too small for the corresponding name, so it was truncated.
E_NOINTERFACE	The specified module was not found.

Remarks

For more information about modules, see [Modules](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugSymbols::GetModuleParameters method

The **GetModuleParameters** method returns parameters for [modules](#) in the target.

Syntax

```
C++
HRESULT GetModuleParameters(
    [in]           ULONG             Count,
    [in, optional] PULONG64        Bases,
    [in]           ULONG             Start,
    [out]          PDEBUG_MODULE_PARAMETERS Params
);
```

Parameters

Count [in]

Specifies the number of modules whose parameters are desired.

Bases [in, optional]

Specifies an array of locations in the target's virtual address space representing the base address of the modules whose parameters are desired. The size of this array is the value of *Count*. If *Bases* is **NULL**, the *Start* parameter is used to specify the modules by index.

Start [in]

Specifies the index of the first module whose parameters are desired. If *Bases* is not **NULL**, this parameter is ignored.

Params [out]

Receives the parameters. The size of this array is the value of *Count*. See [DEBUG_MODULE_PARAMETERS](#).

Return value

This method may also return other error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful. However, if <i>Bases</i> is not NULL , it is possible that not all of the modules were found, in which case partial results are returned.
E_INVALIDARG	When <i>Bases</i> is NULL , this value indicates that the target contains fewer than the sum of <i>Count</i> and <i>Start</i> modules. Partial results are returned.

Remarks

In the cases when partial results are returned, the entries in the array *Params* corresponding to modules that could not be found have their **Base** field set to **DEBUG_INVALID_OFFSET**. See [DEBUG_MODULE_PARAMETERS](#).

For more information about modules, see [Modules](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugSymbols::GetNameByOffset method

The **GetNameByOffset** method returns the name of the symbol at the specified location in the target's virtual address space.

Syntax

```
C++
HRESULT GetNameByOffset(
    [in]        ULONG64  Offset,
    [out, optional] PSTR    NameBuffer,
    [in]        ULONG    NameBufferSize,
    [out, optional] PULONG   NameSize,
    [out, optional] PULONG64 Displacement
);
```

Parameters

Offset [in]

Specifies the location in the target's virtual address space of the symbol whose name is requested. *Offset* does not need to specify the base location of the symbol; it only

needs to specify a location within the symbol's memory allocation.

NameBuffer [out, optional]

Receives the symbol's name. The name is qualified by the module to which the symbol belongs (for example, **mymodule!main**). If *NameBuffer* is **NULL**, this information is not returned.

NameBufferSize [in]

Specifies the size in characters of the buffer *NameBuffer*.

NameSize [out, optional]

Receives the size in characters of the symbol's name. If *NameSize* is **NULL**, this information is not returned.

Displacement [out, optional]

Receives the difference between the value of *Offset* and the base location of the symbol. If *Displacement* is **NULL**, this information is not returned.

Return value

This method may also return other error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
S_FALSE	The method was successful. However, the buffer was not large enough to hold the symbol's name, so it was truncated.
E_FAIL	No symbol could be found at the specified location.

Remarks

For more information about symbols and symbol names, see [Symbols](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugSymbols](#)
[IDebugSymbols2](#)
[IDebugSymbols3](#)
[GetNearNameByOffset](#)
[GetOffsetByName](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugSymbols::GetNearNameByOffset method

The **GetNearNameByOffset** method returns the name of a symbol that is located near the specified location.

Syntax

```
C++  
HRESULT GetNearNameByOffset(  
    [in]          ULONG64  Offset,  
    [in]          LONG     Delta,  
    [out, optional] PSTR    NameBuffer,  
    [in]          ULONG    NameBufferSize,  
    [out, optional] PULONG   NameSize,  
    [out, optional] PULONG64 Displacement  
,
```

Parameters

Offset [in]

Specifies the location in the target's virtual address space of the symbol from which the desired symbol is determined.

Delta [in]

Specifies the relationship between the desired symbol and the symbol located at *Offset*. If positive, the engine will return the symbol that is *Delta* symbols after the symbol located at *Offset*. If negative, the engine will return the symbol that is *Delta* symbols before the symbol located at *Offset*.

NameBuffer [out, optional]

Receives the symbol's name. The name is qualified by the module to which the symbol belongs (for example, `mymodule!main`). If *NameBuffer* is **NULL**, this information is not returned.

NameBufferSize [in]

Specifies the size in characters of the buffer *NameBuffer*.

NameSize [out, optional]

Receives the size in characters of the symbol's name. If *NameSize* is **NULL**, this information is not returned.

Displacement [out, optional]

Receives the difference between the value of *Offset* and the location in the target's memory address space of the symbol. If *Displacement* is **NULL**, this information is not returned.

Return value

This method may also return other error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
S_FALSE	The method was successful. However, the buffer was not large enough to hold the symbol's name so it was truncated.
E_NOINTERFACE	No symbol matching the specifications of <i>Offset</i> and <i>Delta</i> was found.

Remarks

By increasing or decreasing the value of *Delta*, these methods can be used to iterate over the target's symbols starting at a particular location.

If *Delta* is zero, these methods behave the same way as [GetNameByOffset](#).

For more information about symbols and symbol names, see [Symbols](#).

IDebugSymbols::GetNextSymbolMatch method

The **GetNextSymbolMatch** method returns the next symbol found in a symbol search.

Syntax

C++

```
HRESULT GetNextSymbolMatch(
    [in]           ULONG64 Handle,
    [out, optional] PSTR     Buffer,
    [in]           ULONG    BufferSize,
    [out, optional] PULONG   MatchSize,
    [out, optional] PULONG64 Offset
);
```

Parameters

Handle [in]

Specifies the handle returned by [StartSymbolMatch](#) when the search was initialized.

Buffer [out, optional]

Receives the name of the symbol. If *Buffer* is **NULL**, the same symbol will be returned again next time one of these methods are called (with the same handle); this can be used to determine the size of the name of the symbol.

BufferSize [in]

Specifies the size in characters of the buffer.

MatchSize [out, optional]

Receives the size in characters of the name of the symbol. If *MatchSize* is **NULL**, this information is not returned.

Offset [out, optional]

Receives the location in the target's virtual address space of the symbol. If *Offset* is **NULL**, this information is not returned.

Return value

This method may also return other error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
S_FALSE	The size of the buffer was too small for the name of the symbol, or <i>Buffer</i> was NULL .
E_NOINTERFACE	No more symbols were found matching the pattern.

Remarks

The search must first be initialized by [StartSymbolMatch](#). Once all the desired symbols have been found, [EndSymbolMatch](#) can be used to release the resources the engine holds for the search.

For more information about symbols, see [Symbols](#).

Requirements**Target platform**

Header Dbgeng.h (include Dbgeng.h)

IDebugSymbols::GetNumberModules method

The **GetNumberModules** method returns the number of [modules](#) in the current process's module list.

Syntax

C++

```
HRESULT GetNumberModules(
    [out] PULONG Loaded,
    [out] PULONG Unloaded
);
```

Parameters*Loaded* [out]

Receives the number of loaded modules in the current process's module list.

Unloaded [out]

Receives the number of unloaded modules in the current process's module list. This number will be zero if the version of Microsoft Windows running on the target computer does not track unloaded modules.

Return value

This method may also return other error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

The list of loaded and unloaded modules is maintained by Windows. The engine caches a copy of this list, but it may become out of date. [Reload](#) can be used to synchronize the engine's copy of the list with the list maintained by Windows.

The unloaded modules are not tracked in all versions of Windows. Unloaded modules are tracked for user-mode targets in Microsoft Windows Server 2003 and later; for kernel-mode targets, the unloaded modules are tracked in earlier Windows versions as well. When they are tracked they are indexed after the loaded modules. Unloaded modules can be used to analyze failures caused by an attempt to call unloaded code.

For more information about modules, see [Modules](#).

Requirements

IDebugSymbols::GetOffsetByLine method

The `GetOffsetByLine` method returns the location of the instruction that corresponds to a specified line in the source code.

Syntax

```
C++  
HRESULT GetOffsetByLine(  
    [in] ULONG Line,  
    [in] PCSTR File,  
    [out] PULONG64 Offset  
) ;
```

Parameters

Line [in]

Specifies the line number in the source file.

File [in]

Specifies the file name of the source file.

Offset [out]

Receives the location in the target's virtual address space of an instruction for the specified line.

Return value

This method may also return other error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

A line in a source file might correspond to multiple instructions and this method can return any one of these instructions.

For more information about source files, see [Using Source Files](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

IDebugSymbols::GetOffsetByName method

The **GetOffsetByName** method returns the location of a symbol identified by name.

Syntax

```
C++  
HRESULT GetOffsetByName(  
    [in]  PCSTR   Symbol,  
    [out] PULONG64 Offset  
) ;
```

Parameters

Symbol [in]

Specifies the name of the symbol to locate. The name may be qualified by a module name (for example, **mymodule!main**).

Offset [out]

Receives the location in the target's memory address space of the base of the symbol's memory allocation.

Return value

This method may also return other error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
S_FALSE	The method was successful. However, the name <i>Symbol</i> was not unique and multiple symbols with that name were found. One of these symbols was arbitrarily chosen and returned.
E_FAIL	No symbol could be found with the specified name.

Remarks

If the name *Symbol* is not unique and **GetOffsetByName** finds multiple symbols with that name, then the ambiguity will be resolved arbitrarily. In this case the value **S_FALSE** will be returned. [StartSymbolMatch](#) can be used to initiate a search to determine which is the desired result.

GetNameByOffset does not support pattern matching (e.g. wildcards). To find a symbol using pattern matching use [StartSymbolMatch](#).

If the module name for the symbol is known, it is best to qualify the symbol name with the module name. Otherwise the engine will search the symbols for all modules until it finds a match; this can take a long time if it has to load the symbol files for a lot of modules. If the symbol name is qualified with a module name, the engine only searches the symbols for that module.

For more information about symbols and symbol names, see [Symbols](#).

Requirements

IDebugSymbols::GetOffsetTypeId method

The **GetOffsetTypeId** method returns the type ID of the symbol closest to the specified memory location.

Syntax

```
C++  
HRESULT GetOffsetTypeId(  
    [in]          ULONG64  Offset,  
    [out]         PULONG   TypeId,  
    [out, optional] PULONG64 Module  
) ;
```

Parameters

Offset [in]

Specifies the location in the target's memory for the symbol. The symbol closest to this location is used.

TypeId [out]

Receives the type ID of the symbol.

Module [out, optional]

Specifies the location in the target's memory address space of the base of the module to which the symbol belongs. For more information, see [Modules](#). If *Module* is **NULL**, this information is not returned.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful

Remarks

For more information about symbols, see [Symbols](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugSymbols::GetScope method

The **GetScope** method returns information about the current scope.

Syntax

```
C++  
HRESULT GetScope(  
    [out, optional] PULONG64           InstructionOffset,  
    [out, optional] PDEBUG_STACK_FRAME ScopeFrame,  
    [out, optional] PVOID              ScopeContext,  
    [in]          ULONG               ScopeContextSize  
) ;
```

Parameters

InstructionOffset [out, optional]

Receives the location in the process's virtual address space of the current scope's current instruction.

ScopeFrame [out, optional]

Receives the [DEBUG STACK FRAME](#) structure representing the current scope's stack frame.

ScopeContext [out, optional]

Receives the current scope's [thread context](#). The type of the thread context is the CONTEXT structure for the target's effective processor. The buffer *ScopeContext* must be large enough to hold this structure.

ScopeContextSize [in]

Specifies the size of the buffer *ScopeContext*.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
E_INVALIDARG	The size of the buffer <i>ScopeContext</i> was not large enough to hold the scope's context.

Remarks

For more information about scopes, see [Scopes and Symbol Groups](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h or Ntddk.h)

See also

[IDebugSymbols](#)
[IDebugSymbols2](#)
[IDebugSymbols3](#)
[IDebugControl::GetEffectiveProcessorType](#)
[ResetScope](#)
[SetScope](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugSymbols::GetScopeSymbolGroup method

The **GetScopeSymbolGroup** method returns a symbol group containing the symbols in the current target's scope.

Syntax

```
C++
HRESULT GetScopeSymbolGroup(
    [in]           ULONG             Flags,
    [in, optional] PDEBUG_SYMBOL_GROUP Update,
    [out]          PDEBUG_SYMBOL_GROUP *Symbols
);
```

Parameters

Flags [in]

Specifies a bit-set used to determine which symbols to include in the symbol group. To include all symbols, set *Flags* to DEBUG_SCOPE_GROUP_ALL. The following bit-flags determine which symbols are included.

Flag	Description
DEBUG_SCOPE_GROUP_ARGUMENTS	Include the function arguments for the current scope.
DEBUG_SCOPE_GROUP_LOCALS	Include the local variables for the current scope.

Update [in, optional]

Specifies a previously created symbol group that will be updated to reflect the current scope. If *Update* is NULL, a new symbol group interface object is created.

Symbols [out]

Receives the symbol group interface object for the current scope. For details on this interface, see [IDebugSymbolGroup](#).

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

The *Update* parameter allows for efficient updates when stepping through code. Instead of creating and populating a new symbol group, the old symbol group can be updated.

For more information about scopes and symbol groups, see [Scopes and Symbol Groups](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugSymbols::GetSourceFileLineOffsets method

The **GetSourceFileLineOffsets** method maps each line in a source file to a location in the target's memory.

Syntax

```
C++
HRESULT GetSourceFileLineOffsets(
    [in]           PCSTR     File,
    [out, optional] PULONG64 Buffer,
    [in]           ULONG     BufferLines,
    [out, optional] PULONG   FileLines
);
```

Parameters

File [in]

Specifies the name of the file whose lines will be turned into locations in the target's memory. The symbols for each module in the target are queried for this file. If the file is not located, the path is dropped and the symbols are queried again.

Buffer [out, optional]

Receives the locations in the target's memory that correspond to the lines of the source code. The first entry returned to this array corresponds to the first line of the file, so that *Buffer*[*i*] contains the location for line *i*+1. If no symbol information is available for a line, the corresponding entry in *Buffer* is set to DEBUG_INVALID_OFFSET. If *Buffer* is NULL, this information is not returned.

BufferLines [in]

Specifies the number of PULONG64 objects that the *Buffer* array can hold.

FileLines [out, optional]

Receives the number of lines in the source file specified by *File*.

Return value

This method can also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
S_FALSE	The method was successful. However, the number of lines in the source file exceeded the number of entries in the <i>Buffer</i> array and some of the results were discarded.

Remarks

For more information about using the source path, see [Using Source Files](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

IDebugSymbols::GetSourcePath method

The **GetSourcePath** method returns the source path.

Syntax

C++

```
HRESULT GetSourcePath(
    [out, optional] PSTR    Buffer,
    [in]          ULONG   BufferSize,
    [out, optional] PULONG  PathSize
);
```

Parameters

Buffer [out, optional]

Receives the source path. This is a string that contains source path elements separated by semicolons (;). Each source path element can specify either a directory or a source server. If *Buffer* is NULL, this information is not returned.

BufferSize [in]

Specifies the size, in characters, of the *Buffer* buffer.

PathSize [out, optional]

Receives the size, in characters, of the source path.

Return value

This method can also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
S_FALSE	The method was successful. However, the buffer was not large enough to hold the source path and the path was truncated.

Remarks

The source path is used by the engine when searching for source files.

For more information about manipulating the source path, see [Using Source Files](#). For an overview of the source path and its syntax, see [Source Path](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugSymbols::GetSourcePathElement method

The **GetSourcePathElement** method returns an element from the source path.

Syntax

C++

```
HRESULT GetSourcePathElement(
    [in]           ULONG   Index,
    [out, optional] PSTR    Buffer,
    [in]           ULONG   BufferSize,
    [out, optional] PULONG  ElementSize
);
```

Parameters

Index [in]

Specifies the index of the element in the source path that will be returned. The source path is a string that contains elements separated by semicolons (;). The index of the first element is zero.

Buffer [out, optional]

Receives the source path element. Each source path element can be a directory or a source server. If *Buffer* is **NULL**, this information is not returned.

BufferSize [in]

Specifies the size, in characters, of the *Buffer* buffer.

ElementSize [out, optional]

Receives the size, in characters, of the source path element.

Return value

This method can also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
E_NOINTERFACE	The source path contains fewer than <i>Index</i> elements.

Remarks

The source path is used by the engine when searching for source files.

For more information about manipulating the source path, see [Using Source Files](#). For an overview of the source path and its syntax, see [Source Path](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugSymbols::GetSymbolModule method

The **GetSymbolModule** method returns the base address of module which contains the specified symbol.

Syntax

```
C++
HRESULT GetSymbolModule(
    [in]  PCSTR   Symbol,
    [out] PULONG64 Base
);
```

Parameters

Symbol [in]

Specifies the name of the symbol to look up. See the Remarks section for details of the syntax of this name.

Base [out]

Receives the location in the target's memory address space of the base of the module. For more information, see [Modules](#).

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
E_NOINTERFACE	The symbol or module could not be found.

Remarks

The string *Symbol* must contain an exclamation point (!). If *Symbol* is a module-qualified symbol name (for example, **mymodules!main**) or if the module name is omitted (for example, **!main**), the engine will search for this symbol and return the module in which it is found. If *Symbol* contains just a module name (for example, **mymodule!**) the engine returns the first module with this module name.

For more information about symbols, see [Symbols](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugSymbols::GetSymbolOptions method

The **GetSymbolOptions** method returns the engine's global symbol options.

Syntax

```
C++  
HRESULT GetSymbolOptions(  
    [out] PULONG Options  
) ;
```

Parameters

Options [out]

Receives the symbol options bit-set. For a description of the bit flags, see [Setting Symbol Options](#).

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

For more information about symbols, see [Symbols](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h or Dbghelp.h)

IDebugSymbols::GetSymbolPath method

The **GetSymbolPath** method returns the symbol path.

Syntax

```
C++  
HRESULT GetSymbolPath(  
    [out, optional] PSTR    Buffer,  
    [in]          ULONG   BufferSize,  
    [out, optional] PULONG  PathSize
```

```
) ;
```

Parameters

Buffer [out, optional]

Receives the symbol path. This is a string that contains symbol path elements separated by semicolons (;). Each symbol path element can specify either a directory or a symbol server. If *Buffer* is **NULL**, this information is not returned.

BufferSize [in]

Specifies the size, in characters, of the *Buffer* buffer.

PathSize [out, optional]

Receives the size, in characters, of the symbol path.

Return value

These methods can also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
S_FALSE	The method was successful. However, the buffer was not large enough to hold the symbol path and the path was truncated.

Remarks

For more information about manipulating the symbol path, see [Using Symbols](#). For an overview of the symbol path and its syntax, see [Symbol Path](#).

Requirements

Target platform

IDebugSymbols::GetSymbolTypeId method

The **GetSymbolTypeId** method returns the type ID and module of the specified symbol.

Syntax

C++

```
HRESULT GetSymbolTypeId(
    [in]          PCSTR      Symbol,
    [out]         PULONG     TypeId,
    [out, optional] PULONG64  Module
);
```

Parameters

Symbol [in]

Specifies the expression whose type ID is requested. See the Remarks section for details on the syntax of this expression.

TypeId [out]

Receives the type ID.

Module [out, optional]

Receives the base address of the module containing the symbol. For more information, see [Modules](#). If *Module* is **NULL**, this information is not returned.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

The Symbol expression may contain structure fields, pointer dereferencing, and array dereferencing -- for example `my_struct.some_field[0]`.

For more information about symbols, see [Symbols](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[IDebugSymbols](#)
[IDebugSymbols2](#)
[IDebugSymbols3](#)
[GetTypeId](#)
[GetSymbolTypeId](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugSymbols::GetTypeId method

The `GetTypeId` method looks up the specified type and return its type ID.

Syntax

C++
HRESULT GetTypeId(
 [in] ULONG64 Module,
 [in] PCSTR Name,
 [out] PULONG Typeid
) ;

Parameters

Module [in]

Specifies the base address of the module to which the type belongs. For more information, see [Modules](#). If *Name* contains a module name, *Module* is ignored.

Name [in]

Specifies the name of the type whose type ID is desired. If *Name* is a module-qualified name (for example `mymodule!main`), the *Module* parameter is ignored.

TypeId [out]

Receives the type ID of the symbol.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

If the specified symbol is a type, these methods return the type ID for that type; otherwise, they return the type ID for the type of the symbol.

A variable whose type was defined using `typedef` has a type ID that identifies the original type, not the type created by `typedef`. In the following example, the type ID of `MyInstance` corresponds to the name `MyStruct` (this correspondence can be seen by passing the type ID to [GetTypeName](#)):

```
struct MyStruct { int a; };
typedef struct MyStruct MyType;
MyType MyInstance;
```

Moreover, calling these methods for `MyStruct` and `MyType` yields type IDs corresponding to `MyStruct` and `MyType`, respectively.

For more information about symbols and symbol names, see [Symbols](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[IDebugSymbols](#)
[IDebugSymbols2](#)
[IDebugSymbols3](#)
[GetOffsetTypeId](#)
[GetSymbolTypeId](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugSymbols::GetTypeName method

The `GetTypeName` method returns the name of the type symbol specified by its type ID and module.

Syntax

```
C++
HRESULT GetTypeName(
    [in]           ULONG64 Module,
    [in]           ULONG     TypeId,
    [out, optional] PSTR      NameBuffer,
    [in]           ULONG     NameBufferSize,
    [out, optional] PULONG    NameSize
);
```

Parameters

Module [in]

Specifies the base address of the module to which the type belongs. For more information, see [Modules](#).

TypeId [in]

Specifies the type ID of the type.

NameBuffer [out, optional]

Receives the name of the type. If *NameBuffer* is **NULL**, this information is not returned.

NameBufferSize [in]

Specifies the size in characters of the buffer *NameBuffer*.

NameSize [out, optional]

Receives the size in characters of the type's name. If *NameSize* is **NULL**, this information is not returned.

Return value

This method may also return other error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
S_FALSE	The method was successful. However, the buffer was not large enough to hold the name of the type and it was truncated.
E_FAIL	The specified type could not be found in the specified module.

Remarks

For more information about symbols, see [Symbols](#).

IDebugSymbols::GetTypeSize method

The **GetTypeSize** method returns the number of bytes of memory an instance of the specified type requires.

Syntax

```
C++  
HRESULT GetTypeSize(  
    [in] ULONG64 Module,  
    [in] ULONG TypeId,  
    [out] PULONG Size  
) ;
```

Parameters

Module [in]

Specifies the base address of the module containing the type. For more information, see [Modules](#).

TypeId [in]

Specifies the type ID of the type.

Size [out]

Receives the number of bytes of memory an instance of the specified type requires.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful

Remarks

For more information about symbols, see [Symbols](#).

IDebugSymbols::OutputTypedDataPhysical method

The **OutputTypedDataPhysical** method formats the contents of a variable in the target computer's physical memory, and then sends this to the [output callbacks](#).

Syntax

```
C++  
HRESULT OutputTypedDataPhysical(  
    [in] ULONG     OutputControl,  
    [in] ULONG64   Offset,  
    [in] ULONG64   Module,  
    [in] ULONG     TypeId,  
    [in] ULONG     Flags  
) ;
```

Parameters

OutputControl [in]

Specifies the output control used to determine which output callbacks can receive the output. See [DEBUG_OUTCTL_XXX](#) for possible values.

Offset [in]

Specifies the physical address in the target computer's memory of the variable.

Module [in]

Specifies the base address of the module containing the type of the variable.

TypeId [in]

Specifies the type ID of the type of the variable.

Flags [in]

Specifies the bit-set containing the formatting options. See [DEBUG_TYPEOPTS_XXX](#) for possible values.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

This method is only available in kernel mode debugging.

The output produced by this method is the same as for the debugger command **DT**. See [dt \(Display Type\)](#).

For more information about types, see [Types](#). For information about output, see [Input and Output](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugSymbols::OutputTypedDataVirtual method

The **OutputTypedDataVirtual** method formats the contents of a variable in the target's virtual memory, and then sends this to the [output callbacks](#).

Syntax

```
C++  
HRESULT OutputTypedDataVirtual(  
    [in] ULONG     OutputControl,  
    [in] ULONG64   Offset,  
    [in] ULONG64   Module,  
    [in] ULONG     TypeId,  
    [in] ULONG     Flags  
) ;
```

Parameters

OutputControl [in]

Specifies the output control used to determine which output callbacks can receive the output. See [DEBUG_OUTCTL_XXX](#) for possible values.

Offset [in]

Specifies the location in the target's virtual address space of the variable.

Module [in]

Specifies the base address of the module containing the type.

TypeId [in]

Specifies the type ID of the type.

Flags [in]

Specifies the formatting flags. See [DEBUG_TYPEOPTS_XXX](#) for possible values.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

The output produced by this method is the same as for the debugger command **DT**. See [dt \(Display Type\)](#).

For more information about types, see [Types](#). For more information about output, see [Input and Output](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugSymbols::ReadTypedDataPhysical method

The **ReadTypedDataPhysical** method reads the value of a variable from the target computer's physical memory.

Syntax

```
C++  
HRESULT ReadTypedDataPhysical(  
    [in]          ULONG64 Offset,  
    [in]          ULONG64 Module,  
    [in]          ULONG   TypeId,  
    [out]         PVOID   Buffer,  
    [in]          ULONG   BufferSize,  
    [out, optional] PULONG  BytesRead  
) ;
```

Parameters

Offset [in]

Specifies the physical address in the target computer's memory of the variable to be read.

Module [in]

Specifies the base address of the module containing the type of the variable.

TypeId [in]

Specifies the type ID of the type of the variable.

Buffer [out]

Receives the data that was read.

BufferSize [in]

Specifies the size in bytes of the buffer *Buffer*. This is the maximum number of bytes that will be read.

BytesRead [out, optional]

Receives the number of bytes that were read. If *BytesRead* is **NULL**, this information is not returned.

Return value

Return code	Description
S_OK	The method was successful.
S_FALSE	The method was successful. However, the buffer <i>Buffer</i> was not large enough to hold all the data and it was truncated.

This method may also return error values. See [Return Values](#) for more details.

Remarks

This method is only available in kernel mode debugging.

The number of bytes this method attempts to read is the smaller of the size of the buffer and the size of the variable.

This is a convenience method. The same result can be obtained by calling [GetTypeSize](#) and [ReadPhysical](#).

For more information about types, see [Types](#).

Requirements**Target platform**

Header Dbgeng.h (include Dbgeng.h)

IDebugSymbols::ReadTypedDataVirtual method

The **ReadTypedDataVirtual** method reads the value of a variable in the target's virtual memory.

Syntax

```
C++
HRESULT ReadTypedDataVirtual(
    [in]          ULONG64 Offset,
    [in]          ULONG64 Module,
    [in]          ULONG   TypeId,
    [out]         PVOID   Buffer,
    [in]          ULONG   BufferSize,
    [out, optional] PULONG BytesRead
);
```

Parameters*Offset* [in]

Specifies the location in the target's virtual address space of the variable to read.

Module [in]

Specifies the base address of the module containing the type of the variable.

TypeId [in]

Specifies the type ID of the type.

Buffer [out]

Receives the data that is read.

BufferSize [in]

Specifies the size in bytes of the buffer *Buffer*. This is the maximum number of bytes to be read.

BytesRead [out, optional]

Receives the number of bytes that were read. If *BytesRead* is **NULL**, this information is not returned.

Return value

Return code	Description
S_OK	The method was successful.
S_FALSE	The method was successful. However, the buffer <i>Buffer</i> was not large enough to hold all the data and it was truncated.

This method may also return error values. See [Return Values](#) for more details.

Remarks

The number of bytes this method attempts to read is the smaller of the size of the buffer and the size of the variable.

This is a convenience method. The same result can be obtained by calling [GetTypeSize](#) and [ReadVirtual](#).

For more information about types, see [Types](#).

Requirements**Target platform**

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugSymbols::Reload method

The **Reload** method deletes the engine's symbol information for the specified module and reload these symbols as needed.

Syntax

```
C++
HRESULT Reload(
    [in] PCSTR Module
);
```

Parameters*Module* [in]

Specifies the module to reload.

Return value

Return code	Description
S_OK	The method was successful.

This method may also return error values. See [Return Values](#) for more details.

Remarks

This method behaves the same way as the debugger command **.reload**. The *Module* parameter is treated the same way as the arguments to **.reload**. For example, setting the *Module* parameter to "/u ntdll.dll" has the same effect as the command **.reload /u ntdll.dll**.

For more information about symbols, see [Symbols](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugSymbols](#)

[IDebugSymbols3](#)
[.reload \(Reload Module\)](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugSymbols::RemoveSymbolOptions method

The **RemoveSymbolOptions** method turns off some of the engine's global symbol options.

Syntax

```
C++  
HRESULT RemoveSymbolOptions(  
    [in] ULONG Options  
) ;
```

Parameters

Options [in]

Specifies the symbol options to turn off. *Options* is a bit-set; the new value of the symbol options will equal the old value AND NOT the value of *Options*. For a description of the bit flags, see [Setting Symbol Options](#).

Return value

Return code	Description
S_OK	The method was successful.

This method may also return error values. See [Return Values](#) for more details.

Remarks

After the symbol options have been changed, for each client the engine sends out notification to that client's [IDebugEventCallbacks](#) by it passing the DEBUG_CES_SYMBOL_OPTIONS flag to the [IDebugEventCallbacks::ChangeSymbolState](#) method.

For more information about symbols, see [Symbols](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h or Dbghelp.h)

See also

IDebugSymbols::ResetScope method

The **ResetScope** method resets the current scope to the default scope of the current thread.

Syntax

```
C++  
HRESULT ResetScope();
```

Parameters

This method has no parameters.

Return value

Return code	Description
S_OK	The method was successful.

This method may also return error values. See [Return Values](#) for more details.

Remarks

For more information about scopes, see [Scopes and Symbol Groups](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

IDebugSymbols::SetImagePath method

The **SetImagePath** method sets the executable image path.

Syntax

```
C++  
HRESULT SetImagePath(  
    [in] PCSTR Path  
) ;
```

Parameters

Path [in]

Specifies the new executable image path. This is a string that contains directories separated by semicolons (;).

Return value

This method can also return error values. See [Return Values](#) for more details.

Return code	Description

S_OK The method was successful.

Remarks

The executable image path is used by the engine when searching for executable images.

The executable image path can consist of several directories separated by semicolons. These directories are searched in order.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugSymbols](#)

[GetImagePath](#)
[AppendImagePath](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugSymbols::SetScope method

The **SetScope** method sets the current scope.

Syntax

C++

```
HRESULT SetScope(
    [in]           ULONG64      InstructionOffset,
    [in, optional] PDEBUG_STACK_FRAME ScopeFrame,
    [in, optional] PVOID          ScopeContext,
    [in]           ULONG         ScopeContextSize
);
```

Parameters

InstructionOffset [in]

Specifies the location in the process's virtual address space for the scope's current instruction. This is only used if both *ScopeFrame* and *ScopeContext* are **NULL**; otherwise, it is ignored.

ScopeFrame [in, optional]

Specifies the scope's stack frame. For information about this structure, see [DEBUG_STACK_FRAME](#).

ScopeContext [in, optional]

Specifies the scope's [thread context](#). The type of the thread context is the CONTEXT structure for the target's effective processor. The buffer *ScopeContext* must be large enough to hold this structure. If *ScopeContext* is **NULL**, the current [register context](#) is used instead.

ScopeContextSize [in]

Specifies the size of the buffer *ScopeContext*.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The scope identified by <i>InstructionOffset</i> , <i>ScopeFrame</i> , and <i>ScopeContext</i> is the same as the old scope.
S_FALSE	The scope has changed.

Remarks

If only *InstructionOffset* is provided, the scope can be used to look up symbol names; however, the values of these symbols will not be available.

To set the scope to a previous state, *ScopeContext* must be provided. This is not always necessary (for example, if you only wish to access the symbols and not the [registers](#)). To set the scope to a frame on the current stack, [SetScopeFrameByIndex](#) can be used.

For more information about scopes, see [Scopes and Symbol Groups](#).

Requirements

Target platform

IDebugSymbols::SetSourcePath method

The **SetSourcePath** method sets the source path.

Syntax

C++
HRESULT SetSourcePath(
 [in] PCSTR Path
) ;

Parameters

Path [in]

Specifies the new source path. This is a string that contains source path elements separated by semicolons (;). Each source path element can specify either a directory or a source server.

Return value

This method can also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

The source path is used by the engine when searching for source files.

For more information about manipulating the source path, see [Using Source Files](#). For an overview of the source path and its syntax, see [Source Path](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugSymbols::SetSymbolOptions method

The **SetSymbolOptions** method changes the engine's global symbol options.

Syntax

```
C++
HRESULT SetSymbolOptions(
    [in] ULONG Options
);
```

Parameters

Options [in]

Specifies the new symbol options. *Options* is a bit-set; it will replace the existing symbol options. For a description of the bit flags, see [Setting Symbol Options](#).

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

This method will set the engine's global symbol options to those specified in *Options*. Unlike [AddSymbolOptions](#), any symbol options not in the bit-set *Options* will be removed.

After the symbol options have been changed, for each client the engine sends out notification to that client's [IDebugEventCallbacks](#) by passing the DEBUG_CES_SYMBOL_OPTIONS flag to the [IDebugEventCallbacks::ChangeSymbolState](#) method.

For more information about symbols, see [Symbols](#).

Requirements

Target platform	
Header	Dbgeng.h (include Dbgeng.h or Dbghelp.h)

See also

IDebugSymbols::SetSymbolPath method

The **SetSymbolPath** method sets the symbol path.

Syntax

```
C++
HRESULT SetSymbolPath(
    [in] PCSTR Path
);
```

Parameters

Path [in]

Specifies the new symbol path. This is a string that contains symbol path elements separated by semicolons (;). Each symbol path element can specify either a directory or a symbol server.

Return value

This method can also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

For more information about manipulating the symbol path, see [Using Symbols](#). For an overview of the symbol path and its syntax, see [Symbol Path](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

IDebugSymbols::StartSymbolMatch method

The **StartSymbolMatch** method initializes a search for symbols whose names match a given pattern.

Syntax

```
C++  
HRESULT StartSymbolMatch(  
    [in]  PCSTR    Pattern,  
    [out] PULONG64 Handle  
) ;
```

Parameters

Pattern [in]

Specifies the pattern for which to search. The search will return all symbols whose names match this pattern. For details of the syntax of the pattern, see [Symbol Syntax and Symbol Matching](#) and [String Wildcard Syntax](#).

Handle [out]

Receives the handle identifying the search. This handle can be passed to [GetNextSymbolMatch](#) and [EndSymbolMatch](#).

Return value

This method may also return other error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
E_NOINTERFACE	The specified module was not found.

Remarks

This method initializes a symbol search. The results of the search can be obtained by repeated calls to [GetNextSymbolMatch](#). When all the desired results have been found, use [EndSymbolMatch](#) to release resources the engine holds for the search.

For more information about symbols, see [Symbols](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

IDebugSymbols::WriteTypedDataPhysical method

The **WriteTypedDataPhysical** method writes the value of a variable in the target computer's physical memory.

Syntax

```
C++  
HRESULT WriteTypedDataPhysical(  
    [in]          ULONG64 Offset,  
    [in]          ULONG64 Module,  
    [in]          ULONG    TypeId,  
    [in]          PVOID    Buffer,  
    [in]          ULONG    BufferSize,  
    [out, optional] PULONG BytesWritten  
) ;
```

Parameters

Offset [in]

Specifies the physical address in the target computer's memory of the variable.

Module [in]

Specifies the base address of the module containing the type of the variable.

TypeId [in]

Specifies the type ID of the type of the variable.

Buffer [in]

Specifies the buffer containing the data to be written.

BufferSize [in]

Specifies the size in bytes of the buffer *Buffer*. This is the maximum number of bytes to be written.

BytesWritten [out, optional]

Receives the number of bytes that were written. If *BytesWritten* is **NULL**, this information is not returned.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
S_FALSE	The method was successful. All the bytes in the buffer <i>Buffer</i> were written. However, the buffer was smaller than the size of the specified type.

Remarks

This method is only available in kernel mode debugging.

The number of bytes this method attempts to write is the smaller of the size of the buffer and the size of the variable.

This is a convenience method. The same result can be obtained by calling [GetTypeSize](#) and [WritePhysical](#).

For more information about types, see [Types](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugSymbols::WriteTypedDataVirtual method

The **WriteTypedDataVirtual** method writes data to the target's virtual address space. The number of bytes written is the size of the specified type.

Syntax

```
C++  
HRESULT WriteTypedDataVirtual(  
    [in]          ULONG64 Offset,  
    [in]          ULONG64 Module,  
    [in]          ULONG   TypeId,  
    [in]          PVOID   Buffer,  
    [in]          ULONG   BufferSize,  
    [out, optional] PULONG BytesWritten  
) ;
```

Parameters

Offset [in]

Specifies the location in the target's virtual address space where the data will be written.

Module [in]

Specifies the base address of the module containing the type.

TypeId [in]

Specifies the type ID of the type.

Buffer [in]

Specifies the buffer containing the data to be written.

BufferSize [in]

Specifies the size in bytes of the buffer *Buffer*. This is the maximum number of bytes to be written.

BytesWritten [out, optional]

Receives the number of bytes that were written. If *BytesWritten* is **NULL**, this information is not returned.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
S_FALSE	The method was successful. All the bytes in the buffer <i>Buffer</i> were written. However, the buffer was smaller than the size of the type specified.

Remarks

This is a convenience method. The same result can be obtained by calling [GetTypeSize](#) and [WriteVirtual](#).

For more information about types, see [Types](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugSymbols2 interface

Members

The **IDebugSymbols2** interface inherits from [IDebugSymbols](#). **IDebugSymbols2** also has these types of members:

- [Methods](#)

Methods

The **IDebugSymbols2** interface has these methods.

Method	Description
AddTypeOptions	Turns on some type formatting options for output generated by the engine.
GetConstantName	Returns the name of the specified constant.
GetFieldName	Returns the name of a field within a structure.
GetModuleNameString	Returns the name of the specified module.
GetModuleVersionInformation	Returns version information for the specified module.
GetTypeOptions	Returns the type formatting options for output generated by the engine.
RemoveTypeOptions	Turns off some type formatting options for output generated by the engine.
SetTypeOptions	Changes the type formatting options for output generated by the engine.

Requirements

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugSymbols](#)
[IDebugSymbols3](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugSymbols2::AddTypeOptions method

The **AddTypeOptions** method turns on some type formatting options for output generated by the [engine](#).

Syntax

C++

```
HRESULT AddTypeOptions(  
    [in] ULONG Options  
) ;
```

Parameters

Options [in]

Specifies type formatting options to turn on. *Options* is a bit-set that will be ORed with the existing type formatting options. For a description of the bit flags, see [DEBUG_TYPEOPTS XXX](#).

Return value

Return code	Description
S_OK	The method was successful.

This method may also return error values. See [Return Values](#) for more details.

Remarks

After the type options have been changed, for each *client* the engine sends out notification to that client's [IDebugEventCallbacks](#) by passing the DEBUG_CES_TYPE_OPTIONS flag to the [IDebugEventCallbacks::ChangeSymbolState](#) method.

For more information about types, see [Types](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugSymbols2](#)
[IDebugSymbols3](#)

IDebugSymbols2::GetConstantName method

The GetConstantName method returns the name of the specified constant.

Syntax

```
C++
HRESULT GetConstantName(
    [in]           ULONG64 Module,
    [in]           ULONG   TypeId,
    [in]           ULONG64 Value,
    [out, optional] PSTR  NameBuffer,
    [in]           ULONG   NameBufferSize,
    [out, optional] PULONG NameSize
);
```

Parameters

Module [in]

Specifies the base address of the module in which the constant was defined.

TypeId [in]

Specifies the type ID of the constant.

Value [in]

Specifies the value of the constant.

NameBuffer [out, optional]

Receives the constant's name. If *NameBuffer* is **NULL**, this information is not returned.

NameBufferSize [in]

Specifies the size in characters of the buffer *NameBuffer*.

NameSize [out, optional]

Receives the size in characters of the constant's name.

Return value

Return code	Description
S_OK	The method was successful.
	The method was successful. However, the buffer was not large enough for the constant's name and it

S_FALSE

was truncated.

This method can also return error values. For more information, see [Return Values](#).

Remarks

For more information about symbols, see [Symbols](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugSymbols2::GetFieldName method

The **GetFieldName** method returns the name of a field within a structure.

Syntax

C++

```
HRESULT GetFieldName(
    [in]           ULONG64 Module,
    [in]           ULONG   TypeId,
    [in]           ULONG   FieldIndex,
    [out, optional] PSTR  NameBuffer,
    [in]           ULONG   NameBufferSize,
    [out, optional] PULONG NameSize
);
```

Parameters

Module [in]

Specifies the base address of the module in which the structure was defined.

TypeId [in]

Specifies the type ID of the structure.

FieldIndex [in]

Specifies the index of the desired field within the structure.

NameBuffer [out, optional]

Receives the field's name. If *NameBuffer* is **NULL**, this information is not returned.

NameBufferSize [in]

Specifies the size in characters of the buffer *NameBuffer*.

NameSize [out, optional]

Receives the size in characters of the field's name. If *NameSize* is **NULL**, this information is not returned.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
S_FALSE	The method was successful. However, <i>NameBuffer</i> was not large enough to hold the field's name and it was truncated.

Remarks

For more information about symbols, see [Symbols](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugSymbols2::GetModuleNameString method

The **GetModuleNameString** method returns the name of the specified module.

Syntax

```
C++  
HRESULT GetModuleNameString(  
    [in]          ULONG  Which,  
    [in]          ULONG  Index,  
    [in]          ULONG64 Base,  
    [out, optional] PSTR   Buffer,  
    [in]          ULONG  BufferSize,  
    [out, optional] PULONG NameSize  
) ;
```

Parameters

Which [in]

Specifies which of the module's names to return, possible values are:

Value	Description
DEBUG_MODNAME_IMAGE	The image name. This is the name of the executable file, including the extension. Typically, the full path is included in user mode but not in kernel mode.
DEBUG_MODNAME_MODULE	The module name. This is usually just the file name without the extension. In a few cases, the module name differs significantly from the file name.
DEBUG_MODNAME_LOADED_IMAGE	The loaded image name. Unless Microsoft CodeView symbols are present, this is the same as the image name.
DEBUG_MODNAME_SYMBOL_FILE	The symbol file name. The path and name of the symbol file. If no symbols have been loaded, this is the name of the executable file instead.
DEBUG_MODNAME_MAPPED_IMAGE	The mapped image name. In most cases, this is NULL . If the debugger is mapping an image file (for example, during minidump debugging), this is the name of the mapped image.

Index [in]

Specifies the index of the module. If it is set to DEBUG_ANY_ID, the **Base** parameter is used to specify the location of the module instead.

Base [in]

If **Index** is DEBUG_ANY_ID, specifies the location in the target's memory address space of the base of the module. Otherwise it is ignored.

Buffer [out, optional]

Receives the name of the module. If **Buffer** is **NULL**, this information is not returned.

BufferSize [in]

Specifies the size in characters of the buffer **Buffer**.

NameSize [out, optional]

Receives the size in characters of the module's name. If **NameSize** is **NULL**, this information is not returned.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
S_FALSE	The method was successful. However, the size of the buffer was smaller than the size of the module's name so it was truncated to fit in the buffer.

Remarks

For more information about modules, see [Modules](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugSymbols2::GetModuleVersionInformation method

The **GetModuleVersionInformation** method returns version information for the specified module.

Syntax

```
C++  
HRESULT GetModuleVersionInformation(  
    [in]          ULONG     Index,  
    [in]          ULONG64   Base,  
    [in]          PCSTR     Item,  
    [out, optional] PVOID     Buffer,  
    [in]          ULONG     BufferSize,  
    [out, optional] PULONG    VerInfoSize  
) ;
```

Parameters

Index [in]

Specifies the index of the module. If it is set to DEBUG_ANY_ID, the *Base* parameter is used to specify the location of the module instead.

Base [in]

If *Index* is DEBUG_ANY_ID, specifies the location in the target's memory address space of the base of the module. Otherwise it is ignored.

Item [in]

Specifies the version information being requested. This string corresponds to the *lpSubBlock* parameter of the function **VerQueryValue**. For details on the **VerQueryValue** function, see the Platform SDK.

Buffer [out, optional]

Receives the requested version information. If *Buffer* is **NULL**, this information is not returned.

BufferSize [in]

Specifies the size in characters of the buffer *Buffer*.

VerInfoSize [out, optional]

Receives the size in characters of the version information. If *VerInfoSize* is **NULL**, this information is not returned.

Return value

This method may also return other error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
S_FALSE	The size of the buffer was smaller than the size of the version information. In this case the buffer is filled with the truncated version information.
E_NOINTERFACE	The specified module was not found.

Remarks

Module version information is available only for loaded modules and may not be available in all sessions.

For more information about modules, see [Modules](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugSymbols2::GetTypeOptions method

The **GetTypeOptions** method returns the type formatting options for output generated by the engine.

Syntax

```
C++  
HRESULT GetTypeOptions(  
    [out] PULONG Options  
) ;
```

Parameters

Options [out]

Receives the type formatting options. *Options* is a bit-set; for a description of the bit flags, see [DEBUG_TYPEOPTS XXX](#).

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

After the type options have been changed, for each client the engine sends out notification to that client's [IDebugEventCallbacks](#) by passing the DEBUG_CES_TYPE_OPTIONS flag to the [IDebugEventCallbacks::ChangeSymbolState](#) method.

For more information about types, see [Types](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugSymbols2::RemoveTypeOptions method

The **RemoveTypeOptions** method turns off some type formatting options for output generated by the engine.

Syntax

```
C++
HRESULT RemoveTypeOptions(
    [in] ULONG Options
);
```

Parameters

Options [in]

Specifies the type formatting options to turn off. *Options* is a bit-set; the new value of the options will equal the old value AND NOT the value of *Options*. For a description of the bit flags, see [DEBUG_TYPEOPTS XXX](#).

Return value

Return code	Description
S_OK	The method was successful.

This method may also return error values. See [Return Values](#) for more details.

Remarks

After the type options have been changed, for each client the engine sends out notification to that client's [IDebugEventCallbacks](#) by passing the DEBUG_CES_TYPE_OPTIONS flag to the [IDebugEventCallbacks::ChangeSymbolState](#) method.

For more information about types, see [Types](#).

IDebugSymbols2::SetTypeOptions method

The **SetTypeOptions** method changes the type formatting options for output generated by the engine.

Syntax

```
C++
HRESULT SetTypeOptions(
    [in] ULONG Options
);
```

Parameters

Options [in]

Specifies the new value for the type formatting options. *Options* is a bit-set; it will replace the existing options. For a description of the bit flags, see [DEBUG_TYPEOPTS XXX](#).

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

After the type options have been changed, for each client the engine sends out notification to that client's [IDebugEventCallbacks](#) by passing the DEBUG_CES_TYPE_OPTIONS flag to the [IDebugEventCallbacks::ChangeSymbolState](#) method.

For more information about types, see [Types](#).

IDebugSymbols3 interface

Members

The IDebugSymbols3 interface inherits from [IDebugSymbols2](#). IDebugSymbols3 also has these types of members:

- [Methods](#)

Methods

The IDebugSymbols3 interface has these methods.

Method	Description
AddSyntheticModule	Adds a synthetic module to the module list the debugger maintains for the current process.
AddSyntheticModuleWide	Adds a synthetic module to the module list the debugger maintains for the current process.
AddSyntheticSymbol	Adds a synthetic symbol to a module in the current process. (ANSI version)
AddSyntheticSymbolWide	Adds a synthetic symbol to a module in the current process. (Unicode version)
AppendImagePathWide	Appends directories to the executable image path.
AppendSourcePathWide	Appends directories to the source path.
AppendSymbolPathWide	Appends directories to the symbol path.
CreateSymbolGroup2	Creates a new symbol group.
FindSourceFileWide	Searches the source path for a specified source file.
GetConstantNameWide	Returns the name of the specified constant.
GetCurrentScopeFrameIndex	Returns the index of the current stack frame in the call stack.
GetFieldNameWide	Returns the name of a field within a structure.
GetFieldOffsetWide	Returns the offset of a field from the base address of an instance of a type.
GetFieldTypeAndOffset	Returns the type of a field and its offset within a container. (ANSI version)
GetFieldTypeAndOffsetWide	Returns the type of a field and its offset within a container. (Unicode version)
GetFunctionEntryByOffset	Returns the function entry information for a function.
GetImagePathWide	Returns the executable image path.
GetLineByOffsetWide	Returns the source filename and the line number within the source file of an instruction in the target.
GetModuleByModuleName2	Searches through the process's modules for one with the specified name.
GetModuleByModuleName2Wide	Searches through the process's modules for one with the specified name.
GetModuleByModuleNameWide	Searches through the target's modules for one with the specified name.
GetModuleByOffset2	Searches through the process's modules for one whose memory allocation includes the specified location.
GetModuleNameStringWide	Returns the name of the specified module.
GetModuleVersionInformationWide	Returns version information for the specified module.

GetNameByOffsetWide	Returns the name of the symbol at the specified location in the target's virtual address space.
GetNearNameByOffsetWide	Returns the name of a symbol that is located near the specified location.
GetNextSymbolMatchWide	Returns the next symbol found in a symbol search.
GetOffsetByLineWide	Returns the location of the instruction that corresponds to a specified line in the source code.
GetOffsetByNameWide	Returns the location of a symbol identified by name.
GetScopeSymbolGroup2	Returns a symbol group containing the symbols in the current target's scope.
GetSourceEntriesByLine	Queries symbol information and returns locations in the target's memory that correspond to lines in a source file. (ANSI version)
GetSourceEntriesByLineWide	Queries symbol information and returns locations in the target's memory that correspond to lines in a source file. (Unicode version)
GetSourceEntriesByOffset	
GetSourceEntryBySourceEntry	
GetSourceEntryOffsetRegions	
GetSourceEntryString	
GetSourceEntryStringWide	
GetSourceFileLineOffsetsWide	Maps each line in a source file to a location in the target's memory.
GetSourcePathElementWide	Returns an element from the source path.
GetSourcePathWide	Returns the source path.
GetSymbolEntriesByName	Returns the symbols whose names match a given pattern. (ANSI version)
GetSymbolEntriesByNameWide	Returns the symbols whose names match a given pattern. (Unicode version)
GetSymbolEntriesByOffset	Returns the symbols which are located at a specified address.
GetSymbolEntryBySymbolEntry	
GetSymbolEntryByToken	
GetSymbolEntryInformation	Returns the symbol entry information for a symbol.
GetSymbolEntryOffsetRegions	
GetSymbolEntryString	Returns string information for the specified symbol. (ANSI version)
GetSymbolEntryStringWide	Returns string information for the specified symbol. (Unicode version)
GetSymbolModuleWide	Returns the base address of module which contains the specified symbol.
GetSymbolPathWide	Returns the symbol path.
GetSymbolTypeIdWide	Returns the type ID and module of the specified symbol.
GetTypeIdWide	Looks up the specified type and return its type ID.
GetType NameWide	Returns the name of the type symbol specified by its type ID and module.
IsManagedModule	
OutputSymbolByOffset	Looks up a symbol by address and prints the symbol name and other symbol information to the debugger console.
ReloadWide	Deletes the engine's symbol information for the specified module and reload these symbols as needed.
RemoveSyntheticModule	Removes a synthetic module from the module list the debugger maintains for the current process.
RemoveSyntheticSymbol	Removes a synthetic symbol from a module in the current process.
SetImagePathWide	Sets the executable image path.
SetScopeFrameByIndex	Sets the current scope to the scope of one of the frames on the call stack.
SetScopeFromJitDebugInfo	
SetScopeFromStoredEvent	Sets the current scope to the scope of the stored event.
SetSourcePathWide	Sets the source path.
SetSymbolPathWide	Sets the symbol path.
StartSymbolMatchWide	Initializes a search for symbols whose names match a given pattern.

Requirements

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugSymbols](#)
[IDebugSymbols2](#)

IDebugSymbols3::AddSyntheticModule method

The **AddSyntheticModule** method adds a synthetic module to the module list the debugger maintains for the [*current process*](#).

Syntax

C++

```
HRESULT AddSyntheticModule(
    [in] ULONG64 Base,
    [in] ULONG    Size,
    [in] PCSTR   ImagePath,
    [in] PCSTR   ModuleName,
    [in] ULONG    Flags
);
```

Parameters

Base [in]

Specifies the location in the process's virtual address space of the base of the synthetic module.

Size [in]

Specifies the size in bytes of the synthetic module.

ImagePath [in]

Specifies the image name of the synthetic module. This is the name that will be returned as the name of the executable file for the synthetic module. The full path should be included if known.

ModuleName [in]

Specifies the module name for the synthetic module.

Flags [in]

Set to DEBUG_ADDSYNTHMOD_DEFAULT.

Return value

Return code	Description
S_OK	The method was successful.

This method may also return error values. See [Return Values](#) for more details.

Remarks

The memory region of the synthetic module, described by the *Base* and *Size* parameters, must not overlap the memory region of any other module.

If all the modules are reloaded - for example, by calling [Reload](#) with the *Module* parameter set to an empty string - all synthetic modules will be discarded.

For more information about synthetic modules, see [Synthetic Modules](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugSymbols3](#)
[RemoveSyntheticModule](#)
[AddSyntheticSymbol](#)

[Send comments about this topic to Microsoft](#)

IDebugSymbols3::AddSyntheticModuleWide method

The **AddSyntheticModuleWide** method adds a synthetic module to the module list the debugger maintains for the [current process](#).

Syntax

C++

```
HRESULT AddSyntheticModuleWide(
    [in] ULONG64 Base,
    [in] ULONG    Size,
    [in] PCSTR   ImagePath,
    [in] PCSTR   ModuleName,
    [in] ULONG    Flags
);
```

) ;

Parameters

Base [in]

Specifies the location in the process's virtual address space of the base of the synthetic module.

Size [in]

Specifies the size in bytes of the synthetic module.

ImagePath [in]

Specifies the image name of the synthetic module. This is the name that will be returned as the name of the executable file for the synthetic module. The full path should be included if known.

ModuleName [in]

Specifies the module name for the synthetic module.

Flags [in]

Set to DEBUG_ADDSYNTHMOD_DEFAULT.

Return value

Return code	Description
S_OK	The method was successful.

This method may also return error values. See [Return Values](#) for more details.

Remarks

The memory region of the synthetic module, described by the *Base* and *Size* parameters, must not overlap the memory region of any other module.

If all the modules are reloaded - for example, by calling [Reload](#) with the *Module* parameter set to an empty string - all synthetic modules will be discarded.

For more information about synthetic modules, see [Synthetic Modules](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugSymbols3](#)
[RemoveSyntheticModule](#)
[AddSyntheticSymbol](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugSymbols3::AddSyntheticSymbol method

The **AddSyntheticSymbol** method adds a synthetic symbol to a module in the [current process](#).

Syntax

```
C++
HRESULT AddSyntheticSymbol(
    [in]           ULONG64          Offset,
    [in]           ULONG            Size,
    [in]           PCSTR           Name,
    [in]           ULONG            Flags,
    [out, optional] PDEBUG_MODULE_AND_ID Id
);
```

Parameters

Offset [in]

Specifies the location in the process's virtual address space of the synthetic symbol.

Size [in]

Specifies the size in bytes of the synthetic symbol.

Name [in]

Specifies the name of the synthetic symbol.

Flags [in]

Set to DEBUG_ADDSYNTHSYM_DEFAULT.

Id [out, optional]

Receives the [DEBUG_MODULE_AND_ID](#) structure that identifies the synthetic symbol. If *Id* is NULL, this information is not returned.

Return value

Return code	Description
S_OK	The method was successful.

This method may also return error values. See [Return Values](#) for more details.

Remarks

The location of the synthetic symbol must not be the same as the location of another symbol.

If the module containing a synthetic symbol is reloaded - for example, by calling [Reload](#) with the *Module* parameter set to the name of the module - the synthetic symbol will be discarded.

For more information about synthetic symbols, see [Synthetic Symbols](#).

Requirements**Target platform**

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugSymbols3](#)

IDebugSymbols3::AddSyntheticSymbolWide method

The **AddSyntheticSymbolWide** method adds a synthetic symbol to a module in the [current process](#).

Syntax

C++

```
HRESULT AddSyntheticSymbolWide(
    [in]           ULONG64          Offset,
    [in]           ULONG            Size,
    [in]           PCSTR            Name,
    [in]           ULONG            Flags,
    [out, optional] PDEBUG_MODULE_AND_ID Id
);
```

Parameters*Offset* [in]

Specifies the location in the process's virtual address space of the synthetic symbol.

Size [in]

Specifies the size in bytes of the synthetic symbol.

Name [in]

Specifies the name of the synthetic symbol.

Flags [in]

Set to DEBUG_ADDSYNTHSYM_DEFAULT.

Id [out, optional]

Receives the [DEBUG_MODULE_AND_ID](#) structure that identifies the synthetic symbol. If *Id* is NULL, this information is not returned.

Return value

Return code	Description
S_OK	The method was successful.

This method may also return error values. See [Return Values](#) for more details.

Remarks

The location of the synthetic symbol must not be the same as the location of another symbol.

If the module containing a synthetic symbol is reloaded - for example, by calling [Reload](#) with the *Module* parameter set to the name of the module - the synthetic symbol will be discarded.

For more information about synthetic symbols, see [Synthetic Symbols](#).

[IDebugSymbols3](#)
[RemoveSyntheticSymbol](#)
[AddSyntheticModule](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugSymbols3::AppendImagePathWide method

The **AppendImagePathWide** method appends directories to the executable image path.

Syntax

C++

```
HRESULT AppendImagePathWide(
    [in] PCSTR Addition
);
```

Parameters

Addition [in]

Specifies the directories to append to the executable image path. This is a string that contains directory names separated by semicolons (;).

Return value

Return code	Description
S_OK	The method was successful.

This method may also return error values. See [Return Values](#) for more details.

Remarks

The executable image path is used by the [engine](#) when searching for executable images.

The executable image path can consist of several directories separated by semicolons (;). These directories are searched in order.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugSymbols3](#)
[GetImagePath](#)
[SetImagePath](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugSymbols3::AppendSourcePathWide method

The **AppendSourcePathWide** method appends directories to the source path.

Syntax

```
C++  
HRESULT AppendSourcePathWide(  
    [in] PCSTR Addition  
) ;
```

Parameters

Addition [in]

Specifies the directories to append to the source path. This is a string that contains source path elements separated by semicolons (;). Each source path element can specify either a directory or a source server.

Return value

Return code	Description
S_OK	The method was successful.

This method may also return error values. See [Return Values](#) for more details.

Remarks

The source path is used by the engine when searching for source files.

For more information about manipulating the source path, see [Using Source Files](#). For an overview of the source path and its syntax, see [Source Path](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

IDebugSymbols3::AppendSymbolPathWide method

The **AppendSymbolPathWide** method appends directories to the symbol path.

Syntax

```
C++  
HRESULT AppendSymbolPathWide(  
    [in] PCSTR Addition  
) ;
```

Parameters

Addition [in]

Specifies the directories to append to the symbol path. This is a string that contains symbol path elements separated by semicolons (;). Each symbol path element can specify either a directory or a symbol server.

Return value

Return code	Description
S_OK	The method was successful.

This method may also return error values. See [Return Values](#) for more details.

Remarks

For more information about manipulating the symbol path, see [Using Symbols](#). For an overview of the symbol path and its syntax, see [Symbol Path](#).

Requirements

Target platform

See also

[IDebugSymbols](#)
[GetSymbolPath](#)
[SetSymbolPath](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugSymbols3::CreateSymbolGroup2 method

The **CreateSymbolGroup2** method creates a new symbol group.

Syntax

```
C++  
HRESULT CreateSymbolGroup2(  
    [out] IDebugSymbolGroup **Group  
) ;
```

Parameters

Group [out]

Receives an interface pointer for the new [IDebugSymbolGroup](#) object.

Return value

Return code	Description
S_OK	The method was successful.

This method may also return error values. See [Return Values](#) for more details.

Remarks

The newly created symbol group is empty; it does not contain any [symbols](#). Symbols may be added to the symbol group using [IDebugSymbolGroup::AddSymbol](#).

References to the returned object are managed like other COM objects, using the [IUnknown::AddRef](#) and [IUnknown::Release](#) methods. In particular, the [IUnknown::Release](#) method must be called when the returned object is no longer needed. See [Using Client Objects](#) for more information about using COM interfaces in the Debugger Engine API.

For more information about symbol groups, see [Scopes and Symbol Groups](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugSymbols3](#)
[IDebugSymbolGroup](#)
[IDebugSymbolGroup::AddSymbol](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugSymbols3::FindSourceFileWide method

The **FindSourceFileWide** method searches the source path for a specified source file.

Syntax

```
C++  
HRESULT FindSourceFileWide(  
    [in]          ULONG StartElement,  
    [in]          PCWSTR File,  
    [in]          ULONG Flags,  
    [out, optional] PULONG FoundElement,  
    [out, optional] PWSTR Buffer,  
    [in]          ULONG BufferSize,  
    [out, optional] PULONG FoundSize  
) ;
```

Parameters

StartElement [in]

Specifies the index of an element within the source path to start searching from. All elements in the source path before *StartElement* are excluded from the search. The index of the first element is zero. If *StartElement* is greater than or equal to the number of elements in the source path, the filing system is checked directly.

This parameter can be used with *FoundElement* to check for multiple matches in the source path.

File [in]

Specifies the path and file name of the file to search for.

Flags [in]

Specifies the search flags. For a description of these flags, see [DEBUG FIND SOURCE XXX](#).

The flag DEBUG_FIND_SOURCE_TOKEN_LOOKUP should not be set. The flag DEBUG_FIND_SOURCE_NO_SRCSRV is ignored because this method does not include source servers in the search.

FoundElement [out, optional]

Receives the index of the element within the source path that contains the file. If the file was found directly on the filing system (not using the source path) then -1 is returned to *FoundElement*. If *FoundElement* is NULL, this information is not returned.

Buffer [out, optional]

Receives the path and name of the found file. If the flag DEBUG_FIND_SOURCE_FULL_PATH is set, this is the full canonical path name for the file. Otherwise, it is the concatenation of the directory in the source path with the tail of *File* that was used to find the file. If *Buffer* is NULL, this information is not returned.

BufferSize [in]

Specifies the size, in characters, of the *Buffer* buffer.

FoundSize [out, optional]

Specifies the size, in characters, of the name of the file. If *FoundSize* is **NULL**, this information is not returned.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
E_NOINTERFACE	<i>File</i> was not found on the source path.

Remarks

The engine uses the following steps--in order--to search for the file:

1. For each directory in the source path, an attempt is made to find an overlap between the end of the directory path and the beginning of the file path. For example, if the source path contains a directory *C:\a\b\c\d* and *File* is *c\d\samplefile.c*, the file *C:\a\b\c\d\samplefile.c* is a match.

If the flag **DEBUG_FIND_SOURCE_BEST_MATCH** is set, the match with the longest overlap is returned; otherwise, the first match is returned.

2. For each directory in the source path, *File* is appended to the directory. If no match is found, this process is repeated and each time the first directory is removed from the beginning of the file path. For example, if the source path contains a directory *C:\a\b* and *File* is *c\d\samplefile.c*, then the file *C:\a\b\c\samplefile.c* is a match.

The first match found is returned.

3. *File* is looked up directly on the filing system.

Note Any source servers in the source path are ignored. To include the source servers in the search, use [FindSourceFileAndToken](#) with a module address specified in *ModAddr*.

For more information about using the source path, see [Using Source Files](#). For an overview of the source path and its syntax, see [Source Path](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugSymbols3::GetConstantNameWide method

The **GetConstantNameWide** method returns the name of the specified constant.

Syntax

C++

```
HRESULT GetConstantNameWide(
    [in]           ULONG64 Module,
    [in]           ULONG   TypeId,
    [in]           ULONG64 Value,
    [out, optional] PWSTR  NameBuffer,
    [in]           ULONG   NameBufferSize,
    [out, optional] PULONG NameSize
);
```

Parameters

Module [in]

Specifies the base address of the module in which the constant was defined.

TypeId [in]

Specifies the type ID of the constant.

Value [in]

Specifies the value of the constant.

NameBuffer [out, optional]

Receives the constant's name. If *NameBuffer* is **NULL**, this information is not returned.

NameBufferSize [in]

Specifies the size in characters of the buffer *NameBuffer*.

NameSize [out, optional]

Receives the size in characters of the constant's name.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
S_FALSE	The method was successful. However, the buffer was not large enough for the constant's name and it was truncated.

Remarks

For more information about symbols, see [Symbols](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugSymbols3::GetCurrentScopeFrameIndex method

The **GetCurrentScopeFrameIndex** method returns the index of the current stack frame in the call stack.

Syntax

C++

```
HRESULT GetCurrentScopeFrameIndex(
    [out] PULONG Index
);
```

Parameters

Index [out]

Receives the index of the stack frame corresponding to the current scope. The index counts the number of frames from the top of the call stack. The frame at the top of the stack, representing the current call, has index zero.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

If the current scope was set using [SetScope](#), *Index* receives the value of the **FrameNumber** member of the DEBUG_STACK_TRACE structure passed to the *ScopeFrame* parameter of [SetScope](#).

For more information about scopes, see [Scopes and Symbol Groups](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

IDebugSymbols3::GetFieldNameWide method

The **GetFieldNameWide** method returns the name of a field within a structure.

Syntax

```
C++  
HRESULT GetFieldNameWide(  
    [in]           ULONG64 Module,  
    [in]           ULONG   TypeId,  
    [in]           ULONG   FieldIndex,  
    [out, optional] PWSTR  NameBuffer,  
    [in]           ULONG   NameBufferSize,  
    [out, optional] PULONG NameSize  
) ;
```

Parameters

Module [in]

Specifies the base address of the module in which the structure was defined.

TypeId [in]

Specifies the type ID of the structure.

FieldIndex [in]

Specifies the index of the desired field within the structure.

NameBuffer [out, optional]

Receives the field's name. If *NameBuffer* is **NULL**, this information is not returned.

NameBufferSize [in]

Specifies the size in characters of the buffer *NameBuffer*.

NameSize [out, optional]

Receives the size in characters of the field's name. If *NameSize* is **NULL**, this information is not returned.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
S_FALSE	The method was successful. However, <i>NameBuffer</i> was not large enough to hold the field's name and it was truncated.

Remarks

For more information about symbols, see [Symbols](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugSymbols3::GetFieldOffsetWide method

The **GetFieldOffsetWide** method returns the offset of a field from the base address of an instance of a type.

Syntax

```
C++  
HRESULT GetFieldOffsetWide(  
    [in]  ULONG64 Module,  
    [in]  ULONG   TypeId,  
    [in]  PCWSTR  Field,  
    [out] PULONG  Offset  
) ;
```

Parameters

Module [in]

Specifies the module containing the types of both the container and the field.

TypeId [in]

Specifies the type ID of the type containing the field.

Field [in]

Specifies the name of the field whose offset is requested. Subfields may be specified by using a dot-separated path.

Offset [out]

Receives the offset of the specified field from the base memory location of an instance of the type.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
E_NOINTERFACE	The field <i>Field</i> could not be found in the type specified by <i>TypeId</i> .

Remarks

An example of a dot-separated path for the *Field* parameter is as follows. Suppose the MyStruct structure contains a field **MyField** of type MySubStruct, and the MySubStruct structure contains the field **MySubField**. Then the location of this field relative to the location of MyStruct structure can be found by setting the *Field* parameter to "MyField.MySubField".

For more information about types, see [Types](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugSymbols3::GetFieldTypeAndOffset method

The **GetFieldTypeAndOffset** method returns the type of a field and its offset within a container.

Syntax

```
C++  
HRESULT GetFieldTypeAndOffset(  
    [in]          ULONG64 Module,  
    [in]          ULONG   ContainerTypeId,  
    [in]          PCSTR   Field,  
    [out, optional] PULONG FieldTypeId,  
    [out, optional] PULONG Offset  
) ;
```

Parameters

Module [in]

Specifies the module containing the types of both the container and the field.

ContainerTypeId [in]

Specifies the type ID for the container's type. Examples of containers include structures, unions, and classes.

Field [in]

Specifies the name of the field whose type and offset are requested. Subfields may be specified by using a dot-separated path.

FieldTypeId [out, optional]

Receives the type ID of the field.

Offset [out, optional]

Receives the offset of the field *Field* from the base memory location of an instance of the container.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
E_NOINTERFACE	The field <i>Field</i> could not be found in the type specified by <i>ContainerTypeId</i> .

Remarks

An example of a dot-separated path for the *Field* parameter is as follows. Suppose the MyStruct structure contains a field **MyField** of type MySubStruct, and the MySubStruct structure contains the field **MySubField**. Then the type of this field and its location relative to the location of MyStruct structure can be found by passing "MyField.MySubField" as the *Field* parameter to this method.

For more information about types, see [Types](#). For more information about symbols, see [Symbols](#).

IDebugSymbols3::GetFieldTypeAndOffsetWide method

The **GetFieldTypeAndOffsetWide** method returns the type of a field and its offset within a container.

Syntax

```
C++  
HRESULT GetFieldTypeAndOffsetWide(  
    [in]           ULONG64 Module,  
    [in]           ULONG   ContainerTypeId,  
    [in]           PCWSTR  Field,  
    [out, optional] PULONG  FieldTypeId,  
    [out, optional] PULONG  Offset  
) ;
```

Parameters

Module [in]

Specifies the module containing the types of both the container and the field.

ContainerTypeId [in]

Specifies the type ID for the container's type. Examples of containers include structures, unions, and classes.

Field [in]

Specifies the name of the field whose type and offset are requested. Subfields may be specified by using a dot-separated path.

FieldTypeId [out, optional]

Receives the type ID of the field.

Offset [out, optional]

Receives the offset of the field *Field* from the base memory location of an instance of the container.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
E_NOINTERFACE	The field <i>Field</i> could not be found in the type specified by <i>ContainerTypeId</i> .

Remarks

An example of a dot-separated path for the *Field* parameter is as follows. Suppose the MyStruct structure contains a field **MyField** of type MySubStruct, and the MySubStruct structure contains the field **MySubField**. Then the type of this field and its location relative to the location of MyStruct structure can be found by passing "MyField.MySubField" as the *Field* parameter to this method.

For more information about types, see [Types](#). For more information about symbols, see [Symbols](#).

IDebugSymbols3::GetFunctionEntryByOffset method

The **GetFunctionEntryByOffset** method returns the function entry information for a function.

Syntax

```
C++  
HRESULT GetFunctionEntryByOffset(  
    [in]           ULONG64 Offset,  
    [in]           ULONG   Flags,  
    [out, optional] PVOID   Buffer,  
    [in]           ULONG   BufferSize,  
    [out, optional] PULONG  BufferNeeded  
) ;
```

Parameters

Offset [in]

Specifies a location in the current process's virtual address space of the function's implementation. This is the value returned in the *Offset* parameter of [GetNextSymbolMatch](#) and [IDebugSymbolGroup::GetSymbolOffset](#), and the value of the **Offset** field in the [DEBUG_SYMBOL_ENTRY](#) structure.

Flags [in]

Specifies a bit-flag which alters the behavior of this method. If the bit DEBUG_GENTNENT_RAW_ENTRY_ONLY is not set, the engine will provide artificial entries for well known cases. If this bit is set the artificial entries are not used.

Buffer [out, optional]

Receives the function entry information. If the effective processor is an x86, this is the FPO_DATA structure for the function. For all other architectures, this is the IMAGE_FUNCTION_ENTRY structure for that architecture.

BufferSize [in]

Specifies the size of the buffer *Buffer*.

BufferNeeded [out, optional]

Specifies the size of the function entry information.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
S_FALSE	The method was successful, but the buffer was not large enough to hold the function entry information and so the information was truncated to fit.
E_NOINTERFACE	No function entry information was found for the location <i>Offset</i> .

Remarks

The structures FPO_DATA and IMAGE_FUNCTION_ENTRY are documented in "Image Help Library" which is included in Debugging Tools For Windows in the DbgHelp.chm file.

Note The functions in "Image Help Library" and "Debug Help Library", documented in DbgHelp.chm, should not be called by any extension or debugger engine application.

For more information about symbols, see [Symbols](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h or Winnt.h)

IDebugSymbols3::GetImagePathWide method

The **GetImagePathWide** method returns the executable image path.

Syntax

```
C++
HRESULT GetImagePathWide(
    [out, optional] PWSTR Buffer,
    [in]           ULONG BufferSize,
    [out, optional] PULONG PathSize
);
```

Parameters

Buffer [out, optional]

Receives the executable image path. This is a string that contains directories separated by semicolons (;). If *Buffer* is **NULL**, this information is not returned.

BufferSize [in]

Specifies the size, in characters, of the *Buffer* buffer.

PathSize [out, optional]

Receives the size, in characters, of the executable image path.

Return value

This method may also return other error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
S_FALSE	The method was successful. However, the buffer was not large enough to hold the executable image path and the path was truncated.

Remarks

The executable image path is used by the engine when searching for executable images.

The executable image path can consist of several directories separated by semicolons. These directories are searched in order.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugSymbols3::GetLineByOffsetWide method

The **GetLineByOffsetWide** method returns the source filename and the line number within the source file of an instruction in the target.

Syntax

```
C++
HRESULT GetLineByOffsetWide(
    [in]           ULONG64 Offset,
    [out, optional] PULONG   Line,
    [out, optional] PWSTR    FileBuffer,
    [in]           ULONG    FileBufferSize,
    [out, optional] PULONG   FileSize,
    [out, optional] PULONG64 Displacement
);
```

Parameters

Offset [in]

Specifies the location in the target's virtual address space of the instruction for which to return the source file and line number.

Line [out, optional]

Receives the line number within the source file of the instruction specified by *Offset*. If *Line* is **NULL**, this information is not returned.

FileBuffer [out, optional]

Receives the file name of the file that contains the instruction specified by *Offset*. If *FileBuffer* is **NULL**, this information is not returned.

FileBufferSize [in]

Specifies the size, in characters, of the *FileBuffer* buffer.

FileSize [out, optional]

Specifies the size, in characters, of the source filename. If *FileSize* is **NULL**, this information is not returned.

Displacement [out, optional]

Receives the difference between the location specified in *Offset* and the location of the first instruction of the returned line. If *Displacement* is **NULL**, this information is not returned.

Return value

This method may also return other error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
S_FALSE	The method was successful. However, the buffer was not large enough to hold the name of the source file and the name was truncated.

Remarks

For more information about source files, see [Using Source Files](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugSymbols3::GetModuleByModuleName2 method

The **GetModuleByModuleName2** method searches through the process's [modules](#) for one with the specified name.

Syntax

```
C++  
HRESULT GetModuleByModuleName2(  
    [in]          PCSTR      Name,  
    [in]          ULONG       StartIndex,  
    [in]          ULONG       Flags,  
    [out, optional] PULONG     Index,  
    [out, optional] PULONG64   Base  
) ;
```

Parameters

Name [in]

Specifies the name of the desired module.

StartIndex [in]

Specifies the index to start searching from.

Flags [in]

Specifies a bit-set containing options used when searching for the module with the specified name. *Flags* may contain the following bit-flags:

Flag	Effect
DEBUG_GETMOD_NO_LOADED_MODULES	Do not search the loaded modules.
DEBUG_GETMOD_NO_UNLOADED_MODULES	Do not search the unloaded modules.

Index [out, optional]

Receives the index of the first module with the name *Name*. If *Index* is **NULL**, this information is not returned.

Base [out, optional]

Receives the location in the target's memory address space of the base of the module. If *Base* is **NULL**, this information is not returned.

Return value

This method may also return other error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
E_INVALIDARG	One of the arguments passed in was invalid.

Remarks

Starting at the specified index, these methods return the first module they find with the specified name. If the target has more than one module with this name, then subsequent modules can be found by repeated calls to these methods with higher values of *StartIndex*.

For more information about modules, see [Modules](#).

IDebugSymbols3::GetModuleByModuleName2Wide method

The `GetModuleByModuleName2Wide` method searches through the process's [modules](#) for one with the specified name.

Syntax

C++

```
HRESULT GetModuleByModuleName2Wide (
    [in]          PCWSTR   Name,
    [in]          ULONG     StartIndex,
    [in]          ULONG     Flags,
    [out, optional] PULONG   Index,
    [out, optional] PULONG64 Base
);
```

Parameters

Name [in]

Specifies the name of the desired module.

StartIndex [in]

Specifies the index to start searching from.

Flags [in]

Specifies a bit-set containing options used when searching for the module with the specified name. *Flags* may contain the following bit-flags:

Flag	Effect
DEBUG_GETMOD_NO_LOADED_MODULES	Do not search the loaded modules.
DEBUG_GETMOD_NO_UNLOADED_MODULES	Do not search the unloaded modules.

Index [out, optional]

Receives the index of the first module with the name *Name*. If *Index* is **NULL**, this information is not returned.

Base [out, optional]

Receives the location in the target's memory address space of the base of the module. If *Base* is **NULL**, this information is not returned.

Return value

This method may also return other error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
E_INVALIDARG	One of the arguments passed in was invalid.

Remarks

Starting at the specified index, these methods return the first module they find with the specified name. If the target has more than one module with this name, then subsequent modules can be found by repeated calls to these methods with higher values of *StartIndex*.

IDebugSymbols3::GetModuleByModuleNameWide method

The **GetModuleByModuleNameWide** method searches through the target's [modules](#) for one with the specified name.

Syntax

```
C++  
HRESULT GetModuleByModuleNameWide(  
    [in]          PCWSTR  Name,  
    [in]          ULONG   StartIndex,  
    [out, optional] ULONG   Index,  
    [out, optional] PULONG64 Base  
,
```

Parameters

Name [in]

Specifies the name of the desired module.

StartIndex [in]

Specifies the index to start searching from.

Index [out, optional]

Receives the index of the first module with the name *Name*. If *Index* is **NULL**, this information is not returned.

Base [out, optional]

Receives the location in the target's memory address space of the base of the module. If *Base* is **NULL**, this information is not returned.

Return value

This method may also return other error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
E_INVALIDARG	One of the arguments passed in was invalid.

Remarks

Starting at the specified index, these methods return the first module they find with the specified name. If the target has more than one module with this name, then subsequent modules can be found by repeated calls to these methods with higher values of *StartIndex*.

IDebugSymbols3::GetModuleByOffset2 method

The **GetModuleByOffset2** method searches through the process's [modules](#) for one whose memory allocation includes the specified location.

Syntax

C++

```
HRESULT GetModuleByOffset2(
    [in]          ULONG64  Offset,
    [in]          ULONG    StartIndex,
    [in]          ULONG    Flags,
    [out, optional] PULONG  Index,
    [out, optional] PULONG64 Base
);
```

Parameters

Offset [in]

Specifies a location in the target's virtual address space which is inside the desired module's memory allocation -- for example, the address of a symbol belonging to the module.

StartIndex [in]

Specifies the index to start searching from.

Flags [in]

Specifies a bit-set containing options used when searching for the module with the specified location. *Flags* may contain the following bit-flags:

Flag	Effect
DEBUG_GETMOD_NO_LOADED_MODULES	Do not search the loaded modules.
DEBUG_GETMOD_NO_UNLOADED_MODULES	Do not search the unloaded modules.

Index [out, optional]

Receives the index of the module. If *Index* is **NULL**, this information is not returned.

Base [out, optional]

Receives the location in the target's memory address space of the base of the module. If *Base* is **NULL**, this information is not returned.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

Starting at the specified index, this method returns the first module it finds whose memory allocation address range includes the specified location. If the target has more than one module whose memory address range includes this location, then subsequent modules can be found by repeated calls to this method with higher values of *StartIndex*.

For more information about modules, see [Modules](#).

IDebugSymbols3::GetModuleNameStringWide method

The **GetModuleNameStringWide** method returns the name of the specified module.

Syntax

```
C++
HRESULT GetModuleNameStringWide(
    [in]          ULONG   Which,
    [in]          ULONG   Index,
    [in]          ULONG64 Base,
    [out, optional] PWSTR   Buffer,
    [in]          ULONG   BufferSize,
    [out, optional] PULONG  NameSize
);
```

Parameters

Which [in]

Specifies which of the module's names to return, possible values are:

Value	Description
DEBUG_MODNAME_IMAGE	The image name. This is the name of the executable file, including the extension. Typically, the full path is included in user mode but not in kernel mode.
DEBUG_MODNAME_MODULE	The module name. This is usually just the file name without the extension. In a few cases, the module name differs significantly from the file name.
DEBUG_MODNAME_LOADED_IMAGE	The loaded image name. Unless Microsoft CodeView symbols are present, this is the same as the image name.
DEBUG_MODNAME_SYMBOL_FILE	The symbol file name. The path and name of the symbol file. If no symbols have been loaded, this is the name of the executable file instead.
DEBUG_MODNAME_MAPPED_IMAGE	The mapped image name. In most cases, this is NULL . If the debugger is mapping an image file (for example, during minidump debugging), this is the name of the mapped image.

Index [in]

Specifies the index of the module. If it is set to DEBUG_ANY_ID, the *Base* parameter is used to specify the location of the module instead.

Base [in]

If *Index* is DEBUG_ANY_ID, specifies the location in the target's memory address space of the base of the module. Otherwise it is ignored.

Buffer [out, optional]

Receives the name of the module. If *Buffer* is NULL, this information is not returned.

BufferSize [in]

Specifies the size in characters of the buffer *Buffer*.

NameSize [out, optional]

Receives the size in characters of the module's name. If *NameSize* is NULL, this information is not returned.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
S_FALSE	The method was successful. However, the size of the buffer was smaller than the size of the module's name so it was truncated to fit in the buffer.

Remarks

For more information about modules, see [Modules](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

IDebugSymbols3::GetModuleVersionInformationWide method

The **GetModuleVersionInformationWide** method returns version information for the specified module.

Syntax

C++

```
HRESULT GetModuleVersionInformationWide(
    [in]           ULONG   Index,
    [in]           ULONG64 Base,
    [in]           PCWSTR  Item,
    [out, optional] PVOID   Buffer,
    [in]           ULONG   BufferSize,
    [out, optional] PULONG  VerInfoSize
);
```

Parameters

Index [in]

Specifies the index of the module. If it is set to DEBUG_ANY_ID, the *Base* parameter is used to specify the location of the module instead.

Base [in]

If *Index* is DEBUG_ANY_ID, specifies the location in the target's memory address space of the base of the module. Otherwise it is ignored.

Item [in]

Specifies the version information being requested. This string corresponds to the *lpSubBlock* parameter of the function **VerQueryValue**. For details on the **VerQueryValue** function, see the Platform SDK.

Buffer [out, optional]

Receives the requested version information. If *Buffer* is **NULL**, this information is not returned.

BufferSize [in]

Specifies the size in characters of the buffer *Buffer*.

VerInfoSize [out, optional]

Receives the size in characters of the version information. If *VerInfoSize* is **NULL**, this information is not returned.

Return value

This method may also return other error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
S_FALSE	The size of the buffer was smaller than the size of the version information. In this case the buffer is filled with the truncated version information.
E_NOINTERFACE	The specified module was not found.

Remarks

Module version information is available only for loaded modules and may not be available in all sessions.

For more information about modules, see [Modules](#).

IDebugSymbols3::GetNameByOffsetWide method

The **GetNameByOffsetWide** method returns the name of the symbol at the specified location in the target's virtual address space.

Syntax

```
C++
HRESULT GetNameByOffsetWide(
    [in]          ULONG64  Offset,
    [out, optional] PWSTR    NameBuffer,
    [in]          ULONG    NameBufferSize,
    [out, optional] PULONG   NameSize,
    [out, optional] PULONG64 Displacement
);
```

Parameters*Offset* [in]

Specifies the location in the target's virtual address space of the symbol whose name is requested. *Offset* does not need to specify the base location of the symbol; it only needs to specify a location within the symbol's memory allocation.

NameBuffer [out, optional]

Receives the symbol's name. The name is qualified by the module to which the symbol belongs (for example, `mymodule!main`). If `NameBuffer` is `NULL`, this information is not returned.

NameBufferSize [in]

Specifies the size in characters of the buffer `NameBuffer`.

NameSize [out, optional]

Receives the size in characters of the symbol's name. If `NameSize` is `NULL`, this information is not returned.

Displacement [out, optional]

Receives the difference between the value of `Offset` and the base location of the symbol. If `Displacement` is `NULL`, this information is not returned.

Return value

This method may also return other error values. See [Return Values](#) for more details.

Return code	Description
<code>S_OK</code>	The method was successful.
<code>S_FALSE</code>	The method was successful. However, the buffer was not large enough to hold the symbol's name, so it was truncated.
<code>E_FAIL</code>	No symbol could be found at the specified location.

Remarks

For more information about symbols and symbol names, see [Symbols](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

[GetNearNameByOffset](#)
[GetOffsetByName](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugSymbols3::GetNearNameByOffsetWide method

The `GetNearNameByOffsetWide` method returns the name of a symbol that is located near the specified location.

Syntax

```
C++  
HRESULT GetNearNameByOffsetWide(  
    [in]          ULONG64  Offset,  
    [in]          LONG     Delta,  
    [out, optional] PWSTR   NameBuffer,  
    [in]          ULONG    NameBufferSize,  
    [out, optional] PULONG  NameSize,  
    [out, optional] PULONG64 Displacement  
) ;
```

Parameters

Offset [in]

Specifies the location in the target's virtual address space of the symbol from which the desired symbol is determined.

Delta [in]

Specifies the relationship between the desired symbol and the symbol located at `Offset`. If positive, the engine will return the symbol that is `Delta` symbols after the symbol located at `Offset`. If negative, the engine will return the symbol that is `Delta` symbols before the symbol located at `Offset`.

NameBuffer [out, optional]

Receives the symbol's name. The name is qualified by the module to which the symbol belongs (for example, `mymodule!main`). If `NameBuffer` is `NULL`, this information is not returned.

NameBufferSize [in]

Specifies the size in characters of the buffer `NameBuffer`.

NameSize [out, optional]

Receives the size in characters of the symbol's name. If `NameSize` is `NULL`, this information is not returned.

Displacement [out, optional]

Receives the difference between the value of `Offset` and the location in the target's memory address space of the symbol. If `Displacement` is `NULL`, this information is not returned.

Return value

This method may also return other error values. See [Return Values](#) for more details.

Return code	Description
<code>S_OK</code>	The method was successful.
<code>S_FALSE</code>	The method was successful. However, the buffer was not large enough to hold the symbol's name so it was truncated.
<code>E_NOINTERFACE</code>	No symbol matching the specifications of <code>Offset</code> and <code>Delta</code> was found.

Remarks

By increasing or decreasing the value of `Delta`, these methods can be used to iterate over the target's symbols starting at a particular location.

If `Delta` is zero, these methods behave the same way as [GetNameByOffset](#).

For more information about symbols and symbol names, see [Symbols](#).

IDebugSymbols3::GetNextSymbolMatchWide method

The `GetNextSymbolMatchWide` method returns the next symbol found in a symbol search.

Syntax

```
C++  
HRESULT GetNextSymbolMatchWide(  
    [in]           ULONG64 Handle,  
    [out, optional] PWSTR   Buffer,  
    [in]           ULONG   BufferSize,  
    [out, optional] PULONG  MatchSize,  
    [out, optional] PULONG64 Offset  
) ;
```

Parameters

Handle [in]

Specifies the handle returned by [StartSymbolMatch](#) when the search was initialized.

Buffer [out, optional]

Receives the name of the symbol. If `Buffer` is `NULL`, the same symbol will be returned again next time one of these methods are called (with the same handle); this can

be used to determine the size of the name of the symbol.

BufferSize [in]

Specifies the size in characters of the buffer.

MatchSize [out, optional]

Receives the size in characters of the name of the symbol. If *MatchSize* is **NULL**, this information is not returned.

Offset [out, optional]

Receives the location in the target's virtual address space of the symbol. If *Offset* is **NULL**, this information is not returned.

Return value

This method may also return other error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
S_FALSE	The size of the buffer was too small for the name of the symbol, or <i>Buffer</i> was NULL .
E_NOINTERFACE	No more symbols were found matching the pattern.

Remarks

The search must first be initialized by [StartSymbolMatch](#). Once all the desired symbols have been found, [EndSymbolMatch](#) can be used to release the resources the engine holds for the search.

For more information about symbols, see [Symbols](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugSymbols3](#)
[EndSymbolMatch](#)
[StartSymbolMatch](#)

IDebugSymbols3::GetOffsetByLineWide method

The **GetOffsetByLineWide** method returns the location of the instruction that corresponds to a specified line in the source code.

Syntax

C++

```
HRESULT GetOffsetByLineWide(
    [in] ULONG   Line,
    [in] PCWSTR  File,
    [out] PULONG64 Offset
);
```

Parameters

Line [in]

Specifies the line number in the source file.

File [in]

Specifies the file name of the source file.

Offset [out]

Receives the location in the target's virtual address space of an instruction for the specified line.

Return value

This method may also return other error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

A line in a source file might correspond to multiple instructions and this method can return any one of these instructions.

For more information about source files, see [Using Source Files](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugSymbols3](#)
[GetLineByOffset](#)

[Send comments about this topic to Microsoft](#)

IDebugSymbols3::GetOffsetByNameWide method

The **GetOffsetByNameWide** method returns the location of a symbol identified by name.

Syntax

```
C++
HRESULT GetOffsetByNameWide(
    [in] PCWSTR Symbol,
    [out] PULONG64 Offset
);
```

Parameters

Symbol [in]

Specifies the name of the symbol to locate. The name may be qualified by a module name (for example, **mymodule!main**).

Offset [out]

Receives the location in the target's memory address space of the base of the symbol's memory allocation.

Return value

This method may also return other error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
S_FALSE	The method was successful. However, the name <i>Symbol</i> was not unique and multiple symbols with that name were found. One of these symbols was arbitrarily chosen and returned.
E_FAIL	No symbol could be found with the specified name.

Remarks

If the name *Symbol* is not unique and **GetOffsetByName** finds multiple symbols with that name, then the ambiguity will be resolved arbitrarily. In this case the value S_FALSE will be returned. [StartSymbolMatch](#) can be used to initiate a search to determine which is the desired result.

GetNameByOffset does not support pattern matching (e.g. wildcards). To find a symbol using pattern matching use [StartSymbolMatch](#).

If the module name for the symbol is known, it is best to qualify the symbol name with the module name. Otherwise the engine will search the symbols for all modules until it finds a match; this can take a long time if it has to load the symbol files for a lot of modules. If the symbol name is qualified with a module name, the engine only searches the symbols for that module.

For more information about symbols and symbol names, see [Symbols](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugSymbols3](#)
[GetNameByOffset](#)

IDebugSymbols3::GetScopeSymbolGroup2 method

The **GetScopeSymbolGroup2** method returns a symbol group containing the symbols in the current target's scope.

Syntax

C++

```
HRESULT GetScopeSymbolGroup2(
    [in]           ULONG             Flags,
    [in, optional] PDEBUG_SYMBOL_GROUP2 Update,
    [out]          PDEBUG_SYMBOL_GROUP2 *Symbols
);
```

Parameters

Flags [in]

Specifies a bit-set used to determine which symbols to include in the symbol group. To include all symbols, set *Flags* to DEBUG_SCOPE_GROUP_ALL. The following bit-flags determine which symbols are included.

Flag	Description
DEBUG_SCOPE_GROUP_ARGUMENTS	Include the function arguments for the current scope.
DEBUG_SCOPE_GROUP_LOCALS	Include the local variables for the current scope.

Update [in, optional]

Specifies a previously created symbol group that will be updated to reflect the current scope. If *Update* is NULL, a new symbol group interface object is created.

Symbols [out]

Receives the symbol group interface object for the current scope. For details on this interface, see [IDebugSymbolGroup](#)

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

The *Update* parameter allows for efficient updates when stepping through code. Instead of creating and populating a new symbol group, the old symbol group can be updated.

For more information about scopes and symbol groups, see [Scopes and Symbol Groups](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugSymbols3](#)
[IDebugSymbolGroup](#)

IDebugSymbols3::GetSourceEntriesByLine method

The **GetSourceEntriesByLine** method queries symbol information and returns locations in the target's memory that correspond to lines in a source file.

Syntax

```
C++

HRESULT GetSourceEntriesByLine(
    [in]          ULONG             Line,
    [in]          PCSTR            File,
    [in]          ULONG             Flags,
    [out, optional] PDEBUG_SYMBOL_SOURCE_ENTRY Entries,
    [in]          ULONG             EntriesCount,
    [out, optional] PULONG           EntriesAvailable
);
```

Parameters

Line [in]

Specifies the line in the source file for which to query. The number for the first line is 1.

File [in]

Specifies the source file. The symbols for each module in the target are queried for this file.

Flags [in]

Specifies bit flags that control the behavior of this method. *Flags* can be any combination of values from the following table.

Value	Description
DEBUG_GSEL_NO_SYMBOL_LOADS	The debugger engine will only search for the file among the modules whose symbols have already been loaded. Symbols for the other modules will not be loaded.
DEBUG_GSEL_ALLOW_LOWER	If this option is not set, the debugger engine will load the symbols for all modules until it finds the file specified in <i>File</i> .
DEBUG_GSEL_ALLOW_HIGHER	Include all the lines in <i>File</i> before <i>Line</i> in the result.
DEBUG_GSEL_NEAREST_ONLY	Include all the lines in <i>File</i> after <i>Line</i> in the result.
	Only return at most one result. If DEBUG_GSEL_ALLOW_LOWER or DEBUG_GSEL_ALLOW_HIGHER are set, the returned result will be for a line close to <i>Line</i> but cannot be <i>Line</i> if there is no symbol information for that line.

To use the default set of flags, set *Flags* to DEBUG_GSEL_DEFAULT. This has all the flags in the previous table turned off.

Entries [out, optional]

Receives the locations in the target's memory that correspond to the source lines queried for. Each entry in this array is of type [DEBUG_SYMBOL_SOURCE_ENTRY](#) and contains the source line number along with a location in the target's memory.

EntriesCount [in]

Specifies the number of entries in the *Entries* array.

EntriesAvailable [out, optional]

Receives the number of locations that match the query found in the target's memory.

Return value

These methods can also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
S_FALSE	The method was successful. However, the <i>Entries</i> array was not large enough to hold all the results that matched the query and the extra results were discarded.
E_NOINTERFACE	The query yielded no results. This includes the case where the symbol information was not available for the specified file.

Remarks

These methods can be used by debugger applications to fetch locations in the target's memory for setting breakpoints or matching source code with disassembled instructions. For example, setting the flags DEBUG_GSEL_ALLOW_HIGHER and DEBUG_GSEL_NEAREST_ONLY will return the target's memory location for the first piece of code starting at the specified line.

For more information about source files, see [Using Source Files](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

IDebugSymbols3::GetSourceEntriesByLineWide method

The **GetSourceEntriesByLineWide** method queries symbol information and returns locations in the target's memory that correspond to lines in a source file.

Syntax

```
C++
HRESULT GetSourceEntriesByLineWide(
    [in]           ULONG          Line,
    [in]           PCWSTR         File,
    [in]           ULONG          Flags,
    [out, optional] PDEBUG_SYMBOL_SOURCE_ENTRY Entries,
    [in]           ULONG          EntriesCount,
    [out, optional] PULONG        EntriesAvailable
);
```

Parameters

Line [in]

Specifies the line in the source file for which to query. The number for the first line is 1.

File [in]

Specifies the source file. The symbols for each module in the target are queried for this file.

Flags [in]

Specifies bit flags that control the behavior of this method. *Flags* can be any combination of values from the following table.

Value	Description
DEBUG_GSEL_NO_SYMBOL_LOADS	The debugger engine will only search for the file among the modules whose symbols have already been loaded. Symbols for the other modules will not be loaded.
DEBUG_GSEL_ALLOW_LOWER	If this option is not set, the debugger engine will load the symbols for all modules until it finds the file specified in <i>File</i> .
DEBUG_GSEL_ALLOW_HIGHER	Include all the lines in <i>File</i> before <i>Line</i> in the result.
DEBUG_GSEL_NEAREST_ONLY	Include all the lines in <i>File</i> after <i>Line</i> in the result.
	Only return at most one result. If DEBUG_GSEL_ALLOW_LOWER or DEBUG_GSEL_ALLOW_HIGHER are set, the returned result will be for a line close to <i>Line</i> but cannot be <i>Line</i> if there is no symbol information for that line.

To use the default set of flags, set *Flags* to DEBUG_GSEL_DEFAULT. This has all the flags in the previous table turned off.

Entries [out, optional]

Receives the locations in the target's memory that correspond to the source lines queried for. Each entry in this array is of type [DEBUG_SYMBOL_SOURCE_ENTRY](#) and contains the source line number along with a location in the target's memory.

EntriesCount [in]

Specifies the number of entries in the *Entries* array.

EntriesAvailable [out, optional]

Receives the number of locations that match the query found in the target's memory.

Return value

These methods can also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
S_FALSE	The method was successful. However, the <i>Entries</i> array was not large enough to hold all the results that matched the query and the extra results were discarded.
E_NOINTERFACE	The query yielded no results. This includes the case where the symbol information was not available for the specified file.

Remarks

These methods can be used by debugger applications to fetch locations in the target's memory for setting breakpoints or matching source code with disassembled instructions. For example, setting the flags DEBUG_GSEL_ALLOW_HIGHER and DEBUG_GSEL_NEAREST_ONLY will return the target's memory location for the first piece of code starting at the specified line.

For more information about source files, see [Using Source Files](#).

IDebugSymbols3::GetSourceFileLineOffsetsWide method

The **GetSourceFileLineOffsetsWide** method maps each line in a source file to a location in the target's memory.

Syntax

C++

```
HRESULT GetSourceFileLineOffsetsWide(
    [in]          PCWSTR   File,
    [out, optional] PULONG64 Buffer,
    [in]          ULONG     BufferLines,
    [out, optional] PULONG   FileLines
);
```

Parameters

File [in]

Specifies the name of the file whose lines will be turned into locations in the target's memory. The symbols for each module in the target are queried for this file. If the file is not located, the path is dropped and the symbols are queried again.

Buffer [out, optional]

Receives the locations in the target's memory that correspond to the lines of the source code. The first entry returned to this array corresponds to the first line of the file, so that *Buffer*[i] contains the location for line i+1. If no symbol information is available for a line, the corresponding entry in *Buffer* is set to DEBUG_INVALID_OFFSET. If *Buffer* is NULL, this information is not returned.

BufferLines [in]

Specifies the number of PULONG64 objects that the *Buffer* array can hold.

FileLines [out, optional]

Receives the number of lines in the source file specified by *File*.

Return value

This method can also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
S_FALSE	The method was successful. However, the number of lines in the source file exceeded the number of entries in the <i>Buffer</i> array and some of the results were discarded.

Remarks

For more information about using the source path, see [Using Source Files](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugSymbols3::GetSourcePathElementWide method

The **GetSourcePathElementWide** method returns an element from the source path.

Syntax

```
C++
HRESULT GetSourcePathElementWide(
    [in]           ULONG   Index,
    [out, optional] PWSTR   Buffer,
    [in]           ULONG   BufferSize,
    [out, optional] PULONG  ElementSize
);
```

Parameters

Index [in]

Specifies the index of the element in the source path that will be returned. The source path is a string that contains elements separated by semicolons (;). The index of the first element is zero.

Buffer [out, optional]

Receives the source path element. Each source path element can be a directory or a source server. If *Buffer* is **NULL**, this information is not returned.

BufferSize [in]

Specifies the size, in characters, of the *Buffer* buffer.

ElementSize [out, optional]

Receives the size, in characters, of the source path element.

Return value

This method can also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
E_NOINTERFACE	The source path contains fewer than <i>Index</i> elements.

Remarks

The source path is used by the engine when searching for source files.

For more information about manipulating the source path, see [Using Source Files](#). For an overview of the source path and its syntax, see [Source Path](#).

IDebugSymbols3::GetSourcePathWide method

The **GetSourcePathWide** method returns the source path.

Syntax

C++

```
HRESULT GetSourcePathWide(
    [out, optional] PWSTR Buffer,
    [in]          ULONG BufferSize,
    [out, optional] PULONG PathSize
);
```

Parameters

Buffer [out, optional]

Receives the source path. This is a string that contains source path elements separated by semicolons (;). Each source path element can specify either a directory or a source server. If *Buffer* is NULL, this information is not returned.

BufferSize [in]

Specifies the size, in characters, of the *Buffer* buffer.

PathSize [out, optional]

Receives the size, in characters, of the source path.

Return value

This method can also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
S_FALSE	The method was successful. However, the buffer was not large enough to hold the source path and the path was truncated.

Remarks

The source path is used by the engine when searching for source files.

For more information about manipulating the source path, see [Using Source Files](#). For an overview of the source path and its syntax, see [Source Path](#).

IDebugSymbols3::GetSymbolEntriesByName method

The `GetSymbolEntriesByName` method returns the [symbols](#) whose names match a given pattern.

Syntax

```
C++  
HRESULT GetSymbolEntriesByName(  
    [in]          PCSTR             Symbol,  
    [in]          ULONG              Flags,  
    [out, optional] PDEBUG_MODULE_AND_ID  Ids,  
    [in]          ULONG              IdsCount,  
    [out, optional] PULONG            Entries  
) ;
```

Parameters

Symbol [in]

Specifies the pattern used to determine which symbols to return. This method returns the symbols whose name matches the [string wildcard syntax](#) pattern *Symbol*.

Flags [in]

Set to zero.

Ids [out, optional]

Receives the symbols. This is an array of *IdsCount* entries of type [DEBUG_MODULE_AND_ID](#). If *Ids* is **NULL**, this information is not returned.

IdsCount [in]

Specifies the number of entries that the array *Ids* can hold.

Entries [out, optional]

Receives the number of symbols whose names match the pattern *Symbol*. If *entries* is **NULL**, this information is not returned.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

For more information about symbols, see [Symbols](#).

Requirements

Target platform
Header Dbgeng.h (include Dbgeng.h)

See also

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugSymbols3::GetSymbolEntriesByNameWide method

The **GetSymbolEntriesByNameWide** method returns the [symbols](#) whose names match a given pattern.

Syntax

```
C++  
HRESULT GetSymbolEntriesByNameWide(  
    [in]          PCWSTR             Symbol,  
    [in]          ULONG               Flags,  
    [out, optional] PDEBUG_MODULE_AND_ID  Ids,  
    [in]          ULONG               IdsCount,  
    [out, optional] PULONG              Entries  
) ;
```

Parameters

Symbol [in]

Specifies the pattern used to determine which symbols to return. This method returns the symbols whose name matches the [string wildcard syntax](#) pattern *Symbol*.

Flags [in]

Set to zero.

Ids [out, optional]

Receives the symbols. This is an array of *IdsCount* entries of type [DEBUG_MODULE_AND_ID](#). If *Ids* is **NULL**, this information is not returned.

IdsCount [in]

Specifies the number of entries that the array *Ids* can hold.

Entries [out, optional]

Receives the number of symbols whose names match the pattern *Symbol*. If *entries* is **NULL**, this information is not returned.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

For more information about symbols, see [Symbols](#).

[GetSymbolEntriesByOffset](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugSymbols3::GetSymbolEntriesByOffset method

The **GetSymbolEntriesByOffset** method returns the [symbols](#) which are located at a specified address.

Syntax

```
C++
HRESULT GetSymbolEntriesByOffset(
    [in]           ULONG64          Offset,
    [in]           ULONG            Flags,
    [out, optional] PDEBUG_MODULE_AND_ID  Ids,
    [out, optional] PULONG64        Displacements,
    [in]           ULONG            IdsCount,
    [out, optional] PULONG          Entries
);
```

Parameters

Offset [in]

Specifies a location in the process's memory address space within the desired symbol's range. Not all symbols have a known range, so, for best results, use the base address of the symbol.

Flags [in]

Set to zero.

Ids [out, optional]

Receives the symbols. This is an array of *IdsCount* entries of type [DEBUG_MODULE_AND_ID](#). If *Ids* is **NULL**, this information is not returned.

Displacements [out, optional]

Receives the differences between the base addresses of the found symbols and the given address according to the symbol's range.

IdsCount [in]

Specifies the number of entries that the arrays *Ids* and *Displacements* can hold.

Entries [out, optional]

Receives the number of symbols located at *Offset*. If *Entries* is **NULL**, this information is not returned.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

For more information about symbols, see [Symbols](#).

IDebugSymbols3::GetSymbolEntryInformation method

The **GetSymbolEntryInformation** method returns the symbol entry information for a symbol.

Syntax

```
C++
HRESULT GetSymbolEntryInformation(
    [in]  PDEBUG_MODULE_AND_ID  Id,
    [out] PDEBUG_SYMBOL_ENTRY  Info
);
```

Parameters

Id [in]

Specifies the module and symbol ID of the desired symbol. For details on this structure, see [DEBUG_MODULE_AND_ID](#).

Info [out]

Receives the symbol entry information for the symbol. For details on this structure, see [DEBUG_SYMBOL_ENTRY](#).

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

For details on the symbol entry information, see [Scopes and Symbol Groups](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugSymbols3](#)

IDebugSymbols3::GetSymbolEntryString method

The **GetSymbolEntryString** method returns string information for the specified symbol.

Syntax

```
C++  
HRESULT GetSymbolEntryString(  
    [in]          PDEBUG_MODULE_AND_ID Id,  
    [in]          ULONG             Which,  
    [out, optional] PSTR              Buffer,  
    [in]          ULONG             BufferSize,  
    [out, optional] PULONG            StringSize  
,
```

Parameters

Id [in]

Specifies the symbols whose memory regions are being requested. The [DEBUG_MODULE_AND_ID](#) structure contains the module containing the symbol and the symbol ID of the symbol within the module.

Which [in]

Specifies the index of the desired string. Often this is zero, as most symbols contain just one string (their name). But some symbols may contain more than one string -- for example, annotation symbols.

Buffer [out, optional]

Receives the name of the symbol. If *Buffer* is **NULL**, this information is not returned.

BufferSize [in]

Specifies the size in characters of the buffer *Buffer*.

StringSize [out, optional]

Receives the size in characters of the symbol's name. If *StringSize* is **NULL**, this information is not returned.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

For more information about symbols, see [Symbols](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

IDebugSymbols3::GetSymbolEntryStringWide method

The **GetSymbolEntryStringWide** method returns string information for the specified symbol.

Syntax

C++

```
HRESULT GetSymbolEntryStringWide (
    [in]          PDEBUG_MODULE_AND_ID Id,
    [in]          ULONG             Which,
    [out, optional] PWSTR            Buffer,
    [in]          ULONG             BufferSize,
    [out, optional] PULONG           StringSize
);
```

Parameters

Id [in]

Specifies the symbols whose memory regions are being requested. The [DEBUG_MODULE_AND_ID](#) structure contains the module containing the symbol and the symbol ID of the symbol within the module.

Which [in]

Specifies the index of the desired string. Often this is zero, as most symbols contain just one string (their name). But some symbols may contain more than one string -- for example, annotation symbols.

Buffer [out, optional]

Receives the name of the symbol. If *Buffer* is **NULL**, this information is not returned.

BufferSize [in]

Specifies the size in characters of the buffer *Buffer*.

StringSize [out, optional]

Receives the size in characters of the symbol's name. If *StringSize* is **NULL**, this information is not returned.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
-------------	-------------

S_OK The method was successful.

Remarks

For more information about symbols, see [Symbols](#).

Requirements

Target platform

IDebugSymbols3::GetSymbolModuleWide method

The **GetSymbolModuleWide** method returns the base address of module which contains the specified symbol.

Syntax

C++

```
HRESULT GetSymbolModuleWide(
    [in] PCWSTR Symbol,
    [out] PULONG64 Base
);
```

Parameters

Symbol [in]

Specifies the name of the symbol to look up. See the Remarks section for details of the syntax of this name.

Base [out]

Receives the location in the target's memory address space of the base of the module. For more information, see [Modules](#).

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
E_NOINTERFACE	The symbol or module could not be found.

Remarks

The string *Symbol* must contain an exclamation point (!). If *Symbol* is a module-qualified symbol name (for example, **mymodules!main**) or if the module name is omitted (for example, **!main**), the engine will search for this symbol and return the module in which it is found. If *Symbol* contains just a module name (for example, **mymodule!**) the engine returns the first module with this module name.

For more information about symbols, see [Symbols](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugSymbols3::GetSymbolPathWide method

The **GetSymbolPathWide** method returns the symbol path.

Syntax

C++

```
HRESULT GetSymbolPathWide(
    [out, optional] PWSTR Buffer,
    [in]           ULONG   BufferSize,
    [out, optional] PULONG  PathSize
);
```

Parameters

Buffer [out, optional]

Receives the symbol path. This is a string that contains symbol path elements separated by semicolons (;). Each symbol path element can specify either a directory or a symbol server. If *Buffer* is **NULL**, this information is not returned.

BufferSize [in]

Specifies the size, in characters, of the *Buffer* buffer.

PathSize [out, optional]

Receives the size, in characters, of the symbol path.

Return value

These methods can also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
S_FALSE	The method was successful. However, the buffer was not large enough to hold the symbol path and the path was truncated.

Remarks

For more information about manipulating the symbol path, see [Using Symbols](#). For an overview of the symbol path and its syntax, see [Symbol Path](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugSymbols3](#)
[SetSymbolPath](#)
[AppendSymbolPath](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugSymbols3::GetSymbolTypeIdWide method

The **GetSymbolTypeIdWide** method returns the type ID and module of the specified symbol.

Syntax

C++

```
HRESULT GetSymbolTypeIdWide(
    [in]          PCWSTR  Symbol,
    [out]         PULONG   TypeId,
    [out, optional] PULONG64 Module
```

```
) ;
```

Parameters

Symbol [in]

Specifies the expression whose type ID is requested. See the Remarks section for details on the syntax of this expression.

TypeId [out]

Receives the type ID.

Module [out, optional]

Receives the base address of the module containing the symbol. For more information, see [Modules](#). If *Module* is **NULL**, this information is not returned.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful

Remarks

The *Symbol* expression may contain structure fields, pointer dereferencing, and array dereferencing -- for example `my_struct.some_field[0]`.

For more information about symbols, see [Symbols](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugSymbols3](#)
[GetTypeId](#)
[GetSymbolTypeId](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugSymbols3::GetTypeIdWide method

The `GetTypeIdWide` method looks up the specified type and return its type ID.

Syntax

```
++  
HRESULT GetTypeIdWide(  
    [in]  ULONG64 Module,  
    [in]  PCWSTR  Name,  
    [out] PULONG  TypeId  
) ;
```

Parameters

Module [in]

Specifies the base address of the module to which the type belongs. For more information, see [Modules](#). If *Name* contains a module name, *Module* is ignored.

Name [in]

Specifies the name of the type whose type ID is desired. If *Name* is a module-qualified name (for example `mymodule!main`), the *Module* parameter is ignored.

TypeId [out]

Receives the type ID of the symbol.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

If the specified symbol is a type, these methods return the type ID for that type; otherwise, they return the type ID for the type of the symbol.

A variable whose type was defined using `typedef` has a type ID that identifies the original type, not the type created by `typedef`. In the following example, the type ID of `MyInstance` corresponds to the name `MyStruct` (this correspondence can be seen by passing the type ID to [GetTypeName](#)):

```
struct MyStruct { int a; };
typedef struct MyStruct MyType;
MyType MyInstance;
```

Moreover, calling these methods for `MyStruct` and `MyType` yields type IDs corresponding to `MyStruct` and `MyType`, respectively.

For more information about symbols and symbol names, see [Symbols](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugSymbols3](#)
[GetOffsetTypeId](#)
[GetSymbolTypeId](#)

IDebugSymbols3::GetTypeNameWide method

The `GetTypeNameWide` method returns the name of the type symbol specified by its type ID and module.

Syntax

```
C++
HRESULT GetTypeNameWide(
    [in]           ULONG64 Module,
    [in]           ULONG   TypeId,
    [out, optional] PWSTR   NameBuffer,
    [in]           ULONG   NameBufferSize,
    [out, optional] PULONG  NameSize
);
```

Parameters

Module [in]

Specifies the base address of the module to which the type belongs. For more information, see [Modules](#).

TypeId [in]

Specifies the type ID of the type.

NameBuffer [out, optional]

Receives the name of the type. If *NameBuffer* is **NULL**, this information is not returned.

NameBufferSize [in]

Specifies the size in characters of the buffer *NameBuffer*.

NameSize [out, optional]

Receives the size in characters of the type's name. If *NameSize* is **NULL**, this information is not returned.

Return value

This method may also return other error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
S_FALSE	The method was successful. However, the buffer was not large enough to hold the name of the type and it was truncated.
E_FAIL	The specified type could not be found in the specified module.

Remarks

For more information about symbols, see [Symbols](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugSymbols3](#)
[GetTypeSize](#)

[Send comments about this topic to Microsoft](#)

IDebugSymbols3::OutputSymbolByOffset method

The **OutputSymbolByOffset** method looks up a symbol by address and prints the symbol name and other symbol information to the debugger console.

Syntax

```
C++
HRESULT OutputSymbolByOffset(
    [in] ULONG   OutputControl,
    [in] ULONG   Flags,
    [in] ULONG64 Offset
);
```

Parameters

OutputControl [in]

Specifies where to send the output. For possible values, see [DEBUG_OUTCTL_XXX](#).

Flags [in]

Specifies the flags used to determine what information is printed with the symbol.

The following flags can be present:

Bit-flag	Effect
DEBUG_OUTSYM_FORCE_OFFSET	Include the location of the symbol.
DEBUG_OUTSYM_SOURCE_LINE	Include the file name and line number of the source file where the symbol is defined.
DEBUG_OUTSYM_ALLOW_DISPLACEMENT	Do not require an exact match for the symbols location. This allows the <i>Offset</i> parameter to specify any address within the symbol's memory allocation - not just the base address.

Offset [in]

Specifies the location in the process's virtual address space of the symbol to be printed.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
E_NOINTERFACE	No symbol was found at the specified location.

Remarks

For more information about symbols, see [Symbols](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugSymbols3](#)
[GetNameByOffset](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugSymbols3::ReloadWide method

The **ReloadWide** method deletes the engine's symbol information for the specified module and reload these symbols as needed.

Syntax

```
C++  
HRESULT ReloadWide(  
    [in] PCWSTR Module  
) ;
```

Parameters

Module [in]

Specifies the module to reload.

Return value

Return code	Description
S_OK	The method was successful.

This method may also return error values. See [Return Values](#) for more details.

Remarks

This method behaves the same way as the debugger command **.reload**. The *Module* parameter is treated the same way as the arguments to **.reload**. For example, setting the *Module* parameter to "/u ntdll.dll" has the same effect as the command **.reload /u ntdll.dll**.

For more information about symbols, see [Symbols](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugSymbols3](#)
[.reload \(Reload Module\)](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugSymbols3::RemoveSyntheticModule method

The **RemoveSyntheticModule** method removes a synthetic module from the module list the debugger maintains for the current process.

Syntax

```
C++  
HRESULT RemoveSyntheticModule(  
    [in] ULONG64 Base  
) ;
```

Parameters

Base [in]

Specifies the location in the process's virtual address space of the base of the synthetic module.

Return value

Return code	Description
S_OK	The method was successful.
E_INVALIDARG	No synthetic module was found at the specified location. This is returned if a synthetic module at this location was previously removed or discarded.

This method may also return error values. See [Return Values](#) for more details.

Remarks

If all the modules are reloaded - for example, by calling [Reload](#) with the *Module* parameter set to the empty string - all synthetic modules will be discarded.

For more information about synthetic modules, see Synthetic Modules.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugSymbols3](#)
[AddSyntheticModule](#)
[RemoveSyntheticSymbol](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugSymbols3::RemoveSyntheticSymbol method

The **RemoveSyntheticSymbol** method removes a synthetic symbol from a module in the current process.

Syntax

```
C++  
HRESULT RemoveSyntheticSymbol(  
    [in] PDEBUG_MODULE_AND_ID Id  
) ;
```

Parameters

Id [in]

Specifies the synthetic symbol to remove. This must be the same value returned in the *Id* parameter of [AddSyntheticSymbol](#). See [DEBUG_MODULE_AND_ID](#) for details about the type of this parameter.

Return value

Return code	Description
S_OK	The method was successful.
E_INVALIDARG	No synthetic symbol was found at the specified location. This is returned if a synthetic symbol at this location was previously removed or discarded.

This method may also return error values. See [Return Values](#) for more details.

Remarks

If the module containing a synthetic symbol is reloaded - for example, by calling [Reload](#) with the *Module* parameter set to the name of the module - the synthetic symbol will be discarded.

For more information about synthetic symbols, see Synthetic Symbols.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugSymbols3](#)
[AddSyntheticSymbol](#)
[RemoveSyntheticModule](#)

[Send comments about this topic to Microsoft](#)

IDebugSymbols3::SetImagePathWide method

The **SetImagePathWide** method sets the executable image path.

Syntax

```
C++  
HRESULT SetImagePathWide(  
    [in] PCWSTR Path  
) ;
```

Parameters

Path [in]

Specifies the new executable image path. This is a string that contains directories separated by semicolons (:).

Return value

This method can also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

The executable image path is used by the engine when searching for executable images.

The executable image path can consist of several directories separated by semicolons. These directories are searched in order.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugSymbols3](#)
[GetImagePath](#)

[AppendImagePath](#)[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugSymbols3::SetScopeFrameByIndex method

The **SetScopeFrameByIndex** method sets the current scope to the scope of one of the frames on the call stack.

Syntax

C++

```
HRESULT SetScopeFrameByIndex(
    [in] ULONG Index
);
```

Parameters

Index [in]

Specifies the index of the stack frame from which to set the scope. The index counts the number of frames from the top of the call stack. The frame at the top of the stack, representing the current call, has index zero.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

When an event occurs and the [debugger engine](#) breaks into a target, the scope is set to the current function call (the function that was executing when the event occurred). Calling this method with *Index* set to one will change the current scope to the caller of the current function; with *Index* set to two, the scope is changed to the caller's caller, and so on.

For more information about scopes, see [Scopes and Symbol Groups](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[frame \(Set Local Context\)](#)
[GetCurrentScopeFrameIndex](#)
[SetScopeFromStoredEvent](#)
[SetScope](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugSymbols3::SetScopeFromStoredEvent method

The **SetScopeFromStoredEvent** method sets the current scope to the scope of the stored event.

Syntax

C++

```
HRESULT SetScopeFromStoredEvent();
```

Parameters

This method has no parameters.

Return value

Return code	Description
S_OK	The method was successful.

This method may also return error values. See [Return Values](#) for more details.

Remarks

Currently only user-mode [Minidumps](#) can contain a stored event.

The new scope is printed to the debugger console.

For more information about scopes, see [Scopes and Symbol Groups](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

IDebugSymbols3::SetSourcePathWide method

The SetSourcePathWide method sets the source path.

Syntax

```
C++
HRESULT SetSourcePathWide(
    [in] PCWSTR Path
);
```

Parameters

Path [in]

Specifies the new source path. This is a string that contains source path elements separated by semicolons (;). Each source path element can specify either a directory or a source server.

Return value

This method can also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

The source path is used by the engine when searching for source files.

For more information about manipulating the source path, see [Using Source Files](#). For an overview of the source path and its syntax, see [Source Path](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugSymbols3](#)
[AppendSourcePath](#)
[GetSourcePath](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugSymbols3::SetSymbolPathWide method

The SetSymbolPathWide method sets the symbol path.

Syntax

```
C++  
HRESULT SetSymbolPathWide(  
    [in] PCWSTR Path  
>;
```

Parameters

Path [in]

Specifies the new symbol path. This is a string that contains symbol path elements separated by semicolons (;). Each symbol path element can specify either a directory or a symbol server.

Return value

This method can also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

For more information about manipulating the symbol path, see [Using Symbols](#). For an overview of the symbol path and its syntax, see [Symbol Path](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

[AppendSymbolPath](#)
[GetSymbolPath](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugSymbols3::StartSymbolMatchWide method

The StartSymbolMatchWide method initializes a search for symbols whose names match a given pattern.

Syntax

```
C++  
HRESULT StartSymbolMatchWide(  
    [in] PCWSTR Pattern,  
    [out] PULONG64 Handle
```

) ;

Parameters

Pattern [in]

Specifies the pattern for which to search. The search will return all symbols whose names match this pattern. For details of the syntax of the pattern, see [Symbol Syntax and Symbol Matching](#) and [String Wildcard Syntax](#).

Handle [out]

Receives the handle identifying the search. This handle can be passed to [GetNextSymbolMatch](#) and [EndSymbolMatch](#).

Return value

This method may also return other error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
E_NOINTERFACE	The specified module was not found.

Remarks

This method initializes a symbol search. The results of the search can be obtained by repeated calls to [GetNextSymbolMatch](#). When all the desired results have been found, use [EndSymbolMatch](#) to release resources the engine holds for the search.

For more information about symbols, see [Symbols](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugSymbols3](#)
[EndSymbolMatch](#)
[GetNextSymbolMatch](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugSystemObjects interface

Members

The **IDebugSystemObjects** interface inherits from the **IUnknown** interface. **IDebugSystemObjects** also has these types of members:

- [Methods](#)

Methods

The **IDebugSystemObjects** interface has these methods.

Method	Description
GetCurrentProcessDataOffset	Returns the location of the system data structure describing the current process.
GetCurrentProcessExecutableName	Returns the name of executable file loaded in the current process.
GetCurrentProcessHandle	Returns the system handle for the current process.
GetCurrentProcessId	Returns the engine process ID for the current process.
GetCurrentProcessPeb	Returns the process environment block (PEB) of the current process.
GetCurrentProcessSystemId	Returns the system process ID of the current process.
GetCurrentThreadDataOffset	Returns the location of the system data structure for the current thread.
GetCurrentThreadHandle	Returns the system handle for the current thread.
GetCurrentThreadId	Returns the engine thread ID for the current thread.
GetCurrentThreadSystemId	Returns the system thread ID of the current thread.
GetCurrentThreadTeb	Returns the location of the thread environment block (TEB) for the current thread.
GetEventProcess	Returns the engine process ID for the process on which the last event occurred.
GetEventThread	Returns the engine thread ID for the thread on which the last event occurred.

GetNumberOfProcesses	Returns the number of processes for the current target.
GetNumberOfThreads	Returns the number of threads in the current process.
GetProcessIdByDataOffset	Returns the engine process ID for the specified process.
GetProcessIdByHandle	Returns the engine process ID for the specified process.
GetProcessIdByPeb	Returns the engine process ID for the specified process.
GetProcessIdBySystemId	Returns the engine process ID for a process specified by its system process ID.
GetProcessIdsByIndex	Returns the engine process ID and system process ID for the specified processes in the current target.
GetThreadIdByDataOffset	Returns the engine thread ID for the specified thread.
GetThreadIdByHandle	Returns the engine thread ID for the specified thread.
GetThreadIdByProcessor	Returns the engine thread ID for the kernel-modevirtual thread corresponding to the specified processor.
GetThreadIdBySystemId	Returns the engine thread ID for the specified thread.
GetThreadIdByTeb	Returns the engine thread ID of the specified thread.
GetThreadIdsByIndex	Returns the engine and system thread IDs for the specified threads in the current process.
GetTotalNumberOfThreads	Returns the total number of threads for all the processes in the current target, in addition to the largest number of threads in any process for the current target.
SetCurrentProcessId	Makes the specified process the current process.
SetCurrentThreadId	Makes the specified thread the current thread.

Requirements

Header Dbgeng.h (include Dbgeng.h)

See also

IDebugSystemObjects2
IDebugSystemObjects3
IDebugSystemObjects4

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugSystemObjects::GetCurrentProcessDataOffset method

The **GetCurrentProcessDataOffset** method returns the location of the system data structure describing the current process.

Syntax

```
C++  
HRESULT GetCurrentProcessDataOffset(  
    [out] PULONG64 Offset  
) ;
```

Parameters

Offset [out]

Receives the location in the target's virtual address space of the system data structure describing the current process.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

In user-mode debugging, the location returned is of the process environment block (PEB) for the current process. This is the same location returned by [GetCurrentProcessPeb](#).

In kernel-mode debugging, the location returned is of the KPROCESS structure for the system process in which the last event occurred.

Note In kernel mode, the current process of the target is always the single virtual process the [debugger engine](#) created for the kernel. However, because events may occur in different system processes, the KPROCESS location returned by this method may change.

For more information about processes, see [Threads and Processes](#). For details about the PEB and KPROCESS structures, see *Microsoft Windows Internals* by David Solomon and Mark Russinovich.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugSystemObjects::GetCurrentProcessExecutableName method

The **GetCurrentProcessExecutableName** method returns the name of executable file loaded in the current process.

Syntax

C++

```
HRESULT GetCurrentProcessExecutableName(
    [out, optional] PSTR     Buffer,
    [in]          ULONG    BufferSize,
    [out, optional] PULONG   ExeSize
);
```

Parameters

Buffer [out, optional]

Receives the name of the executable file. If *Buffer* is **NULL**, this information is not returned.

BufferSize [in]

Specifies the size in characters of the buffer *Buffer*.

ExeSize [out, optional]

Receives the size in characters of the name of the executable file. If *ExeSize* is **NULL**, this information is not returned.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
S_FALSE	The method was successful. However, the buffer was not large enough to hold the name of the executable file and it was truncated.

Remarks

These methods are only available in user-mode debugging.

If the engine cannot determine the name of the executable file, it writes the string "?NoImage?" to the buffer.

For more information about processes, see [Threads and Processes](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugSystemObjects::GetCurrentProcessHandle method

The **GetCurrentProcessHandle** method returns the system handle for the current process.

Syntax

```
C++  
HRESULT GetCurrentProcessHandle(  
    [out] PULONG64 Handle  
) ;
```

Parameters

Handle [out]

Receives the system handle of the current process.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

In kernel-mode debugging, the only process in the target is the virtual process created for the kernel. In this case, an artificial handle is created. The artificial handle can only be used with the debugger engine API.

For more information about processes, see [Threads and Processes](#). For details on system handles, see [Handles](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugSystemObjects::GetCurrentProcessId method

The **GetCurrentProcessId** method returns the engine process ID for the current process.

Syntax

```
C++  
HRESULT GetCurrentProcessId(  
    [out] PULONG Id  
) ;
```

Parameters

Id [out]

Receives the engine process ID for the current process.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

For more information about processes, see [Threads and Processes](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugSystemObjects::GetCurrentProcessPeb method

The **GetCurrentProcessPeb** method returns the process environment block (PEB) of the current process.

Syntax

```
C++  
HRESULT GetCurrentProcessPeb(  
    [out] PULONG64 Offset  
) ;
```

Parameters

Offset [out]

Receives the location in the target's virtual address space of the PEB of the current process.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

In user-mode debugging, this method provides the same information as [GetCurrentProcessDataOffset](#).

In kernel-mode debugging, the location returned is that of the PEB structure for the system process in which the last event occurred.

Note In kernel mode, the current process of the target is always the single virtual process the [debugger engine](#) created for the kernel. However, because events may occur in different system processes, the PEB location returned by this method may change.

For more information about processes, see [Threads and Processes](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugSystemObjects::GetCurrentProcessSystemId method

The **GetCurrentProcessSystemId** method returns the system process ID of the current process.

Syntax

```
C++  
HRESULT GetCurrentProcessSystemId(  
    [out] PULONG SysId  
) ;
```

Parameters

SysId [out]

Receives the system process ID.

Return value

This method may also return other error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
E_NOTIMPL	The target is a kernel-mode target.

Remarks

This method is only available in user-mode debugging.

For more information about processes, see [Threads and Processes](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugSystemObjects::GetCurrentThreadDataOffset method

The **GetCurrentThreadDataOffset** method returns the location of the system data structure for the current thread.

Syntax

C++

```
HRESULT GetCurrentThreadDataOffset(
    [out] PULONG64 Offset
);
```

Parameters

Offset [out]

Receives the location of the system data structure for the current thread.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

In user-mode debugging, the location returned is of the thread environment block (TEB) for the current thread. This is the same location returned by [GetCurrentThreadTeb](#).

In kernel-mode debugging, the location returned is of the KTHREAD structure of the system thread that was executing on the processor represented by the current thread when the last event occurred.

Note In kernel mode debugging, the current thread is always a virtual thread the [debugger engine](#) created for a processor in the target computer. Because events may occur in different system threads, the KTHREAD location for a virtual thread may change.

For more information about threads, see [Threads and Processes](#). For details on the KTHREAD and TEB structures, see *Microsoft Windows Internals* by David Solomon and Mark Russinovich.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugSystemObjects::GetCurrentThreadHandle method

The **GetCurrentThreadHandle** method returns the system handle for the current thread.

Syntax

```
C++
HRESULT GetCurrentThreadHandle(
    [out] PULONG64 Handle
);
```

Parameters

Handle [out]

Receives the current thread's system handle.

Return value

This method may also return other error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

In kernel-mode debugging, an artificial handle is created because the threads are virtual threads.

For more information about threads, see [Threads and Processes](#). For details on system handles, see [Handles](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugSystemObjects::GetCurrentThreadId method

The **GetCurrentThreadId** method returns the engine thread ID for the current thread.

Syntax

```
C++
HRESULT GetCurrentThreadId(
    [out] PULONG Id
);
```

Parameters

Id [out]

Receives the engine thread ID.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

For more information about threads, see [Threads and Processes](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugSystemObjects::GetCurrentThreadId method

The **GetCurrentThreadId** method returns the system thread ID of the current thread.

Syntax

C++

```
HRESULT GetCurrentThreadId (
    [out] PULONG SysId
);
```

Parameters

SysId [out]

Receives the system thread ID.

Return value

This method may also return other error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
E_NOTIMPL	The target is a kernel-mode target.

Remarks

This method is only available in user-mode debugging.

For more information about threads, see [Threads and Processes](#).

Requirements

Target platform

Version

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugSystemObjects::GetCurrentThreadTeb method

The **GetCurrentThreadTeb** method returns the location of the thread environment block (TEB) for the current thread.

Syntax

C++

```
HRESULT GetCurrentThreadTeb (
    [out] PULONG64 Offset
```

```
) ;
```

Parameters

Offset [out]

Receives the location in the target's virtual address space of the TEB for the current thread.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

In user-mode debugging, this method provides the same information as [GetCurrentThreadDataOffset](#).

In kernel-mode debugging, the location returned is of the TEB structure of the system thread that was executing on the processor represented by the current thread when the last event occurred.

Note In kernel mode, the current thread is always a virtual thread the debugger created for a processor in the target computer. Because events may occur in different system threads, the TEB location for a virtual thread may change.

For more information about threads, see [Threads and Processes](#). For details on the TEB structure, see *Microsoft Windows Internals* by David Solomon and Mark Russinovich.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugSystemObjects::GetEventProcess method

The GetEventProcess method returns the engine process ID for the process on which the last event occurred.

Syntax

```
C++  
HRESULT GetEventProcess(  
    [out] PULONG Id  
) ;
```

Parameters

Id [out]

Receives the engine process ID.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

In kernel-mode debugging, the engine process ID for the virtual process representing the kernel is returned.

For more information about processes, see [Threads and Processes](#). For details about debugger engine events, see [Monitoring Events](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugSystemObjects::GetEventThread method

The **GetEventThread** method returns the engine thread ID for the thread on which the last event occurred.

Syntax

```
C++  
HRESULT GetEventThread(  
    [out] PULONG Id  
) ;
```

Parameters

Id [out]

Receives the engine thread ID.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

In kernel-mode debugging, the engine thread ID for the virtual thread representing the processor on which the event occurred is returned.

For more information about threads, see [Threads and Processes](#). For details about debugger engine events, see [Monitoring Events](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugSystemObjects::GetNumberProcesses method

The **GetNumberProcesses** method returns the number of [processes](#) for the current target.

Syntax

```
C++  
HRESULT GetNumberProcesses(  
    [out] PULONG Number  
) ;
```

Parameters

Number [out]

Receives the number of processes.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

In kernel-mode debugging, there is only a single virtual process representing the kernel.

In user-mode debugging, the number of processes changes with the create-process and exit-process debugging [events](#).

For more information about processes, see [Threads and Processes](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugSystemObjects::GetNumberThreads method

The GetNumberThreads method returns the number of [threads](#) in the current process.

Syntax

C++

```
HRESULT GetNumberThreads(
    [out] PULONG Number
);
```

Parameters

Number [out]

Receives the number of threads in the current process.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

In kernel-mode debugging, there is a virtual thread representing each processor.

In user-mode debugging, the number of threads changes with the [IDebugEventCallbacks::CreateThread](#) and [IDebugEventCallbacks::ExitThread](#) events.

For more information about threads, see [Threads and Processes](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugSystemObjects::GetProcessIdByDataOffset method

The GetProcessIdByDataOffset method returns the engine process ID for the specified process. The process is specified by its data offset.

Syntax

```
C++
HRESULT GetProcessIdByDataOffset(
    [in]  ULONG64 Offset,
    [out] PULONG Id
);
```

Parameters

Offset [in]

Specifies the location in the target's virtual address space of the data offset of the process.

Id [out]

Receives the engine process ID for the process.

Return value

This method may also return other error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
E_NOTIMPL	The current target is a kernel-mode target. This method is currently not available in kernel-mode debugging.

Remarks

This method is currently not available in kernel-mode debugging.

In user-mode debugging, this method behaves the same as [GetProcessIdByPeb](#).

For more information about processes, see [Threads and Processes](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugSystemObjects::GetProcessIdByHandle method

The **GetProcessIdByHandle** method returns the engine process ID for the specified process. The process is specified by its system handle.

Syntax

```
C++
HRESULT GetProcessIdByHandle(
    [in]  ULONG64 Handle,
    [out] PULONG Id
);
```

Parameters

Handle [in]

Specifies the handle of the process whose process ID is requested. This handle must be a process handle previously retrieved from the debugger engine.

Id [out]

Receives the engine process ID.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
--------------------	--------------------

S_OK The method was successful.

Remarks

For more information about processes, see [Threads and Processes](#). For details on system handles, see [Handles](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugSystemObjects::GetProcessIdByPeb method

The **GetProcessIdByPeb** method returns the engine process ID for the specified process. The process is specified by its process environment block (PEB).

Syntax

C++

```
HRESULT GetProcessIdByPeb(
    [in]  ULONG64 Offset,
    [out] PULONG Id
);
```

Parameters

Offset [in]

Specifies the location in the target's virtual address space of the PEB of the process whose process ID is requested.

Id [out]

Receives the engine process ID.

Return value

This method may also return other error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
E_NOTIMPL	The target is a kernel-mode target. This method is currently not available in kernel-mode debugging.

Remarks

This method is not available in kernel-mode debugging.

For more information about processes, see [Threads and Processes](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugSystemObjects::GetProcessIdBySystemId method

The **GetProcessIdBySystemId** method returns the engine process ID for a process specified by its system process ID.

Syntax

```
C++
HRESULT GetProcessIdBySystemId(
    [in]     ULONG   SysId,
    [out]    PULONG  Id
);
```

Parameters

SysId [in]

Specifies the system process ID.

Id [out]

Receives the engine process ID.

Return value

This method may also return other error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
E_NOTIMPL	The target is a kernel-mode target.

Remarks

This method is only available in user-mode debugging.

For more information about processes, see [Threads and Processes](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugSystemObjects::GetProcessIdsByIndex method

The **GetProcessIdsByIndex** method returns the engine process ID and system process ID for the specified [processes](#) in the current target.

Syntax

```
C++
HRESULT GetProcessIdsByIndex(
    [in]         ULONG   Start,
    [in]         ULONG   Count,
    [out, optional] PULONG  Ids,
    [out, optional] PULONG  SysIds
);
```

Parameters

Start [in]

Specifies the index of the first process whose ID is requested.

Count [in]

Specifies the number of processes whose IDs are requested.

Ids [out, optional]

Receives the engine process IDs. If *Ids* is **NULL**, this information is not returned; otherwise, *Ids* is treated as an array of *Count* **ULONG** values.

SysIds [out, optional]

Receives the system process IDs. If *SysIds* is **NULL**, this information is not returned; otherwise, *SysIds* is treated as an array of *Count* **ULONG** values.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

The index of the first process is zero. The index of the last process is the number of processes returned by [GetNumberProcesses](#) minus one.

For more information about processes, see [Threads and Processes](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugSystemObjects::GetThreadIdByDataOffset method

The **GetThreadIdByDataOffset** method returns the engine thread ID for the specified thread. The thread is specified by its system data structure.

Syntax

C++

```
HRESULT GetThreadIdByDataOffset(
    [in]  ULONG64 Offset,
    [out] PULONG Id
);
```

Parameters

Offset [in]

Specifies the location of the system data structure for the thread.

Id [out]

Receives the engine thread ID.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

In kernel-mode debugging, this method returns the engine thread ID for the virtual thread representing the processor on which the specified thread is executing. If the thread is not executing on a processor, this method will fail.

For more information about threads, see [Threads and Processes](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugSystemObjects::GetThreadIdByHandle method

The **GetThreadIdByHandle** method returns the engine thread ID for the specified thread. The thread is specified by its system handle.

Syntax

```
C++  
HRESULT GetThreadIdByHandle(  
    [in]  ULONG64 Handle,  
    [out] PULONG Id  
) ;
```

Parameters

Handle [in]

Specifies the system handle of the thread whose thread ID is requested.

Id [out]

Receives the engine thread ID.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

In kernel-mode debugging, because the handle is an artificial handle for a processor, this method returns the engine thread ID for the virtual thread representing that processor.

For more information about threads, see [Threads and Processes](#). For details on system handles, see [Handles](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugSystemObjects::GetThreadIdByProcessor method

The **GetThreadIdByProcessor** method returns the engine thread ID for the kernel-mode virtual thread corresponding to the specified processor.

Syntax

```
C++  
HRESULT GetThreadIdByProcessor(  
    [in]  ULONG Processor,  
    [out] PULONG Id  
) ;
```

Parameters

Processor [in]

Specifies the processor corresponding to the desired thread.

Id [out]

Receives the engine thread ID.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

This method is only available in kernel-mode debugging.

For more information about threads, see [Threads and Processes](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugSystemObjects::GetThreadIdBySystemId method

The **GetThreadIdBySystemId** method returns the engine thread ID for the specified thread. The thread is specified by its system thread ID.

Syntax

C++

```
HRESULT GetThreadIdBySystemId(
  [in]  ULONG SysId,
  [out] PULONG Id
);
```

Parameters

SysId [in]

Specifies the system thread ID.

Id [out]

Receives the engine thread ID.

Return value

This method may also return other error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
E_NOTIMPL	The target is a kernel-mode target.

Remarks

This method is only available in user-mode debugging.

For more information about threads, see [Threads and Processes](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugSystemObjects::GetThreadIdByTeb method

The **GetThreadIdByTeb** method returns the engine thread ID of the specified thread. The thread is specified by its thread environment block (TEB).

Syntax

```
C++  
HRESULT GetThreadIdByTeb(  
    [in]    ULONG64 Offset,  
    [out]   PULONG Id  
) ;
```

Parameters

Offset [in]

Specifies the location of the thread's TEB.

Id [out]

Receives the engine thread ID.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

In kernel-mode debugging, this method returns the engine thread ID for the virtual thread representing the processor on which the specified thread is executing. If the thread is not executing on a processor, this method will fail.

For more information about threads, see [Threads and Processes](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugSystemObjects::GetThreadIdsByIndex method

The **GetThreadIdsByIndex** method returns the engine and system thread IDs for the specified [threads](#) in the current process.

Syntax

```
C++  
HRESULT GetThreadIdsByIndex(  
    [in]        ULONG Start,  
    [in]        ULONG Count,  
    [out, optional] PULONG Ids,  
    [out, optional] PULONG SysIds  
) ;
```

Parameters

Start [in]

Specifies the index of the first thread whose IDs are requested.

Count [in]

Specifies the number of threads whose IDs are requested.

Ids [out, optional]

Receives the engine thread IDs. If *Ids* is **NULL**, this information is not returned; otherwise, *Ids* is treated as an array of *Count* ULONG values.

SysIds [out, optional]

Receives the system thread IDs. If *SysIds* is **NULL**, this information is not returned; otherwise, *SysIds* is treated as an array of *Count* ULONG values.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

The index of the first thread is zero. The index of the last thread is the number of threads returned by [GetNumberOfThreads](#) minus one.

For more information about threads, see [Threads and Processes](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugSystemObjects::GetTotalNumberThreads method

The **GetTotalNumberThreads** method returns the total number of [threads](#) for all the [processes](#) in the current target, in addition to the largest number of threads in any process for the current target.

Syntax

```
C++  
HRESULT GetTotalNumberThreads(  
    [out] PULONG Total,  
    [out] PULONG LargestProcess  
) ;
```

Parameters

Total [out]

Receives the total number of threads for all the processes in the current target.

LargestProcess [out]

Receives the largest number of threads in any process for the current target.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

For more information about threads, see [Threads and Processes](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugSystemObjects::SetCurrentProcessId method

The **SetCurrentProcessId** method makes the specified process the current process.

Syntax

```
C++  
HRESULT SetCurrentProcessId(  
    [in] ULONG Id  
) ;
```

Parameters

Id [in]

Specifies the engine process ID for the process that is to become the current process.

Return value

This method may also return other error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
E_NOINTERFACE	No process with the given process ID was found.
E_FAIL	No suitable candidate for the current thread could be found in the process.

Remarks

This method also changes the current thread, and may change the current target and current computer.

If the process is changed, the callback [IDebugEventCallbacks::ChangeEngineState](#) will be called with the DEBUG_CES_CURRENT_THREAD bit set.

Note In kernel-mode debugging, the current process is a virtual process, it is not a system process. This method cannot be used to change between system processes in kernel-mode debugging. However, the implicit process may be changed by using [SetImplicitProcessDataOffset](#).

For more information about processes, see [Threads and Processes](#). For details on monitoring events, see [Monitoring Events](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugSystemObjects::SetCurrentThreadId method

The **SetCurrentThreadId** method makes the specified thread the current thread.

Syntax

```
C++  
HRESULT SetCurrentThreadId(  
    [in] ULONG Id  
) ;
```

Parameters

Id [in]

Specifies the engine thread ID of the thread that is to become the current thread.

Return value

This method may also return other error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
E_NOINTERFACE	No thread with the specified ID was found.

Remarks

This method may also change the current process, current target, and current computer.

If the thread is changed, the callback [IDebugEventCallbacks::ChangeEngineState](#) will be called with the DEBUG_CES_CURRENT_THREAD bit set.

Note In kernel-mode debugging, the current thread is a virtual thread, it is not a system thread. This method cannot be used to change between system threads in kernel-mode debugging. However, the implicit thread may be changed by using [SetImplicitThreadDataOffset](#).

For more information about threads, see [Threads and Processes](#). For details on monitoring events, see [Monitoring Events](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugSystemObjects2 interface

Members

The IDebugSystemObjects2 interface inherits from [IDebugSystemObjects](#). IDebugSystemObjects2 also has these types of members:

- [Methods](#)

Methods

The IDebugSystemObjects2 interface has these methods.

Method	Description
GetCurrentProcessUpTime	Returns the length of time the current process has been running.
GetImplicitProcessDataOffset	Returns the implicit process for the current target.
GetImplicitThreadDataOffset	Returns the implicit thread for the current process.
SetImplicitProcessDataOffset	Sets the implicit process for the current target.
SetImplicitThreadDataOffset	Sets the implicit thread for the current process.

Requirements

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugSystemObjects](#)
[IDebugSystemObjects3](#)
[IDebugSystemObjects4](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugSystemObjects2::GetCurrentProcessUpTime method

The **GetCurrentProcessUpTime** method returns the length of time the current process has been running.

Syntax

```
C++  
HRESULT GetCurrentProcessUpTime(  
    [out] PULONG UpTime  
) ;
```

Parameters

UpTime [out]

Receives the number of seconds the current process has been running.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugSystemObjects2::GetImplicitProcessDataOffset method

The **GetImplicitProcessDataOffset** method returns the implicit process for the current target.

Syntax

```
C++  
HRESULT GetImplicitProcessDataOffset(  
    [out] PULONG64 Offset  
) ;
```

Parameters

Offset [out]

Receives the location in the target's memory address space of the data structure of the system process that is the implicit process for the current target.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

In kernel-mode debugging, the data structure is the KPROCESS structure for the process.

In user-mode debugging, the data structure is the process environment block (PEB) for the process.

For more information about the implicit process, see [Threads and Processes](#). For details on the KPROCESS and PEB structures, see *Microsoft Windows Internals* by David Solomon and Mark Russinovich.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugSystemObjects2::GetImplicitThreadDataOffset method

The **GetImplicitThreadDataOffset** method returns the implicit thread for the current process.

Syntax

C++

```
HRESULT GetImplicitThreadDataOffset(
    [out] PULONG64 Offset
);
```

Parameters

Offset [out]

Receives the location in the target's memory address space of the data structure of the system thread that is the implicit thread for the current process.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

In kernel-mode debugging, the data structure is the KTHREAD structure for the process.

In user-mode debugging, the data structure is the thread environment block (TEB) for the process.

For more information about the implicit thread, see [Threads and Processes](#). For details on the KTHREAD structure and TEB, see *Microsoft Windows Internals* by David Solomon and Mark Russinovich.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugSystemObjects2::SetImplicitProcessDataOffset method

The **SetImplicitProcessDataOffset** method sets the implicit process for the current target.

Syntax

C++

```
HRESULT SetImplicitProcessDataOffset(
    [in] ULONG64 Offset
);
```

Parameters

Offset [in]

Specifies the location in the target's memory address space of the data structure of the system process that is to become the implicit process for the current target. If this is zero, the implicit process for the current target is set to the default implicit process.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

In kernel-mode debugging, the data structure is the KPROCESS structure for the process.

In user-mode debugging, the data structure is the process environment block (PEB) for the process.

Warning Because it is possible to use [SetImplicitThreadDataOffset](#) to set the implicit thread independently of the implicit process, the implicit thread might not belong to the implicit process. This can cause errors if you attempt to access any of the user state for the implicit thread, because it will be incompatible with the virtual address space (specified by the implicit process).

For more information about the current implicit process, see [Threads and Processes](#). For details on the KPROCESS and PEB structures, see *Microsoft Windows Internals* by David Solomon and Mark Russinovich.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugSystemObjects2::SetImplicitThreadDataOffset method

The **SetImplicitThreadDataOffset** method sets the implicit thread for the current process.

Syntax

C++

```
HRESULT SetImplicitThreadDataOffset(
    [in] ULONG64 Offset
);
```

Parameters

Offset [in]

Specifies the location in the target's memory address space of the data structure of the system thread that is to become the implicit thread for the current process. If this is zero, the implicit thread for the current process is set to the default implicit thread.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

In kernel-mode debugging, the data structure is the KTHREAD structure for the process.

In user-mode debugging, the data structure is the thread environment block (TEB) for the process.

Warning Because it is possible to use [SetImplicitProcessDataOffset](#) to set the implicit process independently of the implicit thread, the implicit thread might not belong to the implicit process. This can cause errors if you attempt to access any of the user state for the implicit thread, because it will be incompatible with the virtual address space (specified by the implicit process).

For more information about the current implicit thread, see [Threads and Processes](#). For details on the KTHREAD structure and TEB, see *Microsoft Windows Internals* by David Solomon and Mark Russinovich.

IDebugSystemObjects3 interface

Members

The **IDebugSystemObjects3** interface inherits from [IDebugSystemObjects2](#). **IDebugSystemObjects3** also has these types of members:

- [Methods](#)

Methods

The **IDebugSystemObjects3** interface has these methods.

Method	Description
GetCurrentSystemId	Returns the engine target ID for the current process.
GetCurrentSystemServer	
GetCurrentSystemServerName	
GetEventSystem	Returns the engine target ID for the target in which the last event occurred.
GetNumberSystems	Returns the number of targets to which the engine is currently connected.
GetSystemByServer	
GetSystemIdsByIndex	Returns the engine target IDs for the specified targets.
GetTotalNumberOfThreadsAndProcesses	Returns the total number of threads and processes in all the targets the engine is attached to, in addition to the largest number of threads and processes in a target.
SetCurrentSystemId	Makes the specified target the current target.

Requirements

Header Dbgeng.h (include Dbgeng.h)

IDebugSystemObjects3::GetCurrentSystemId method

The **GetCurrentSystemId** method returns the engine target ID for the current process.

Syntax

C++
HRESULT GetCurrentSystemId(
 [out] PULONG Id
);

Parameters

Id [out]

Receives the engine target ID.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugSystemObjects3](#)
[IDebugSystemObjects4](#)
[Debugging Session and Execution Model](#)

IDebugSystemObjects3::GetEventSystem method

The **GetEventSystem** method returns the engine target ID for the target in which the last event occurred.

Syntax

```
C++  
HRESULT GetEventSystem(  
    [out] PULONG Id  
) ;
```

Parameters

Id [out]

Receives the engine target ID.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugSystemObjects3](#)
[IDebugSystemObjects4](#)
[Monitoring Events](#)
[Debugging Session and Execution Model](#)

[Send comments about this topic to Microsoft](#)

IDebugSystemObjects3::GetNumberSystems method

The **GetNumberSystems** method returns the number of targets to which the engine is currently connected.

Syntax

```
C++
HRESULT GetNumberSystems(
    [out] PULONG Number
);
```

Parameters

Number [out]

Receives the number of targets.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

IDebugSystemObjects3::GetSystemIdsByIndex method

The `GetSystemIdsByIndex` method returns the engine target IDs for the specified targets.

Syntax

```
C++
HRESULT GetSystemIdsByIndex(
    [in] ULONG Start,
    [in] ULONG Count,
    [out] PULONG Ids
);
```

Parameters

Start [in]

Specifies the index of the first target whose target ID is requested.

Count [in]

Specifies the number of processes whose IDs are requested.

Ids [out]

Receives the engine target IDs. If *Ids* is **NULL**, this information is not returned; otherwise, *Ids* is treated as an array of *Count* `ULONG` values.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

The index of the first target is zero. The index of the last target is the number of targets returned by [GetNumberSystems](#) minus one.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugSystemObjects3](#)

IDebugSystemObjects3::GetTotalNumberThreadsAndProcesses method

The **GetTotalNumberThreadsAndProcesses** method returns the total number of [threads](#) and [processes](#) in all the targets the engine is attached to, in addition to the largest number of threads and processes in a target.

Syntax

```
C++  
HRESULT GetTotalNumberThreadsAndProcesses(  
    [out] PULONG TotalThreads,  
    [out] PULONG TotalProcesses,  
    [out] PULONG LargestProcessThreads,  
    [out] PULONG LargestSystemThreads,  
    [out] PULONG LargestSystemProcesses  
) ;
```

Parameters

TotalThreads [out]

Receives the total number of threads in all processes in all targets.

TotalProcesses [out]

Receives the total number of processes in all targets.

LargestProcessThreads [out]

Receives the largest number of threads in any process on any target.

LargestSystemThreads [out]

Receives the largest number of threads in any target.

LargestSystemProcesses [out]

Receives the largest number of processes in any target.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.

Remarks

If no target is found, all the values are set to zero.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugSystemObjects3](#)
[IDebugSystemObjects4](#)
[Threads and Processes](#)

© 2016 Microsoft. All rights reserved.

IDebugSystemObjects3::SetCurrentSystemId method

The **SetCurrentSystemId** method makes the specified target the current target.

Syntax

```
C++  
HRESULT SetCurrentSystemId(  
    [in] ULONG Id  
) ;
```

Parameters

Id [in]

Specifies the engine target ID for the target that is to become the current target.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
E_NOINTERFACE	No process with the given ID was found.

Remarks

This method also sets the current thread and current process, and may change the current computer.

If the current target is changed, the callback [IDebugEventCallbacks::ChangeEngineState](#) will be called with the DEBUG_CES_CURRENT_THREAD bit set.

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugSystemObjects3](#)

IDebugSystemObjects4 interface

Members

The **IDebugSystemObjects4** interface inherits from [IDebugSystemObjects3](#). **IDebugSystemObjects4** also has these types of members:

- [Methods](#)

Methods

The **IDebugSystemObjects4** interface has these methods.

Method	Description
GetCurrentProcessExecutableNameWide	Returns the name of executable file loaded in the current process.
GetCurrentSystemServerNameWide	

Requirements

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugSystemObjects](#)
[IDebugSystemObjects2](#)
[IDebugSystemObjects3](#)

[Send comments about this topic to Microsoft](#)

IDebugSystemObjects4::GetCurrentProcessExecutableNameWide method

The **GetCurrentProcessExecutableNameWide** method returns the name of executable file loaded in the current process.

Syntax

```
C++  
HRESULT GetCurrentProcessExecutableNameWide(  
    [out, optional] PWSTR Buffer,  
    [in]          ULONG   BufferSize,  
    [out, optional] PULONG ExeSize  
) ;
```

Parameters

Buffer [out, optional]

Receives the name of the executable file. If *Buffer* is **NULL**, this information is not returned.

BufferSize [in]

Specifies the size in characters of the buffer *Buffer*.

ExeSize [out, optional]

Receives the size in characters of the name of the executable file. If *ExeSize* is **NULL**, this information is not returned.

Return value

This method may also return error values. See [Return Values](#) for more details.

Return code	Description
S_OK	The method was successful.
S_FALSE	The method was successful. However, the buffer was not large enough to hold the name of the executable file and it was truncated.

Remarks

These methods are only available in user-mode debugging.

If the engine cannot determine the name of the executable file, it writes the string "?NoImage?" to the buffer.

For more information about processes, see [Threads and Processes](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

Callback Debug Engine Interfaces

This section covers the following interfaces:

- [IDebugEventCallbacks](#)
- [IDebugEventCallbacksWide](#)
- [IDebugInputCallbacks](#)
- [IDebugOutputCallbacks](#)
- [IDebugOutputCallbacksWide](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugEventCallbacks interface

Members

The **IDebugEventCallbacks** interface inherits from the **IUnknown** interface. **IDebugEventCallbacks** also has these types of members:

- [Methods](#)

Methods

The **IDebugEventCallbacks** interface has these methods.

Method	Description
Breakpoint	This method is called by the engine when the target issues a breakpoint exception.
ChangeDebuggeeState	This method is called by the engine when it makes or detects changes to the target.
ChangeEngineState	This method is called by the engine when its state has changed.
ChangeSymbolState	This method is called by the engine when the symbol state changes.
CreateProcess	This method is called by the engine when a create-process debugging event occurs in the target.
CreateThread	This method is called by the engine when a create-thread debugging event occurs in the target.
Exception	This method is called by the engine when an exception debugging event occurs in the target.
ExitProcess	This method is called by the engine when an exit-process debugging event occurs in the target.
ExitThread	This method is called by the engine when an exit-thread debugging event occurs in the target.
GetInterestMask	This method is called to determine which events the IDebugEventCallbacks object is interested in.
LoadModule	This method is called by the engine when a module-load debugging event occurs in the target.
SessionStatus	This method is called by the engine when a change occurs in the debugger session.
SystemError	This method is called by the engine when a system error occurs in the target.
UnloadModule	This method is called by the engine when a module-unload debugging event occurs in the target.

Remarks

The [IDebugEventCallbacksWide](#) interface includes Unicode versions of these methods; the Unicode methods share the same names as those used by the methods in **IDebugEventCallbacks**.

Requirements

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugEventCallbacks::Breakpoint method

The **Breakpoint** callback method is called by the engine when the target issues a breakpoint exception.

Syntax

```
C++
HRESULT Breakpoint(
    [in] PDEBUG_BREAKPOINT Bp
);
```

Parameters

Bp [in]

Specifies a pointer to the [IDebugBreakpoint](#) object corresponding to the breakpoint that was triggered.

Return value

This method returns a [DEBUG_STATUS_XXX](#) value, which indicates how the execution of the target should proceed after the engine processes this event. For details on how the engine treats this value, see [Monitoring Events](#).

Remarks

If the breakpoint has an associated command, the engine executes that command before calling this method.

The engine will only call this method if an [IDebugBreakpoint](#) object corresponding to the breakpoint exists in the engine, and--if the breakpoint is a private breakpoint--this [IDebugEventCallbacks](#) object was registered with the client that added the breakpoint.

The engine calls this method only if the DEBUG_EVENT_BREAKPOINT flag is set in the mask returned by [IDebugEventCallbacks::GetInterestMask](#).

Because the engine deletes the corresponding [IDebugBreakpoint](#) object when a breakpoint is removed (for example, by using [RemoveBreakpoint](#)), the value of *Bp* might be invalid after **Breakpoint** returns. Therefore, implementations of [IDebugEventCallbacks](#) should not access *Bp* after **Breakpoint** returns.

For more information about handling events, see [Monitoring Events](#). For information about managing breakpoints, see [Breakpoints](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugEventCallbacks::ChangeDebuggeeState method

The **ChangeDebuggeeState** callback method is called by the engine when it makes or detects changes to the target.

Syntax

```
C++
HRESULT ChangeDebuggeeState(
    [in] ULONG    Flags,
    [in] ULONG64 Argument
);
```

Parameters

Flags [in]

Specifies the type of changes made to the target. *Flags* may take one of the following values:

Value	Description
DEBUG_CDS_ALL	A general change in the target has occurred. For example, the target has been executing, or the engine has just attached to the target.
DEBUG_CDS_REGISTERS	The processor registers for the target have changed.
DEBUG_CDS_DATA	The target's data space has changed.
DEBUG_CDS_REFRESH	Inform the GUI clients to refresh debugger windows.

Argument [in]

Provides additional information about the change in the target. The interpretation of the value of *Argument* depends on the value of *Flags*:

DEBUG_CDS_ALL

The value of *Argument* is zero.

DEBUG_CDS_REGISTERS

If a single register has changed, the value of *Argument* is the index of that register. Otherwise, the value of *Argument* is DEBUG_ANY_ID.

DEBUG_CDS_DATA

The value of *Argument* specifies which data space was changed. The following table contains the possible values of *Argument*.

Value	Description
DEBUG_DATA_SPACE_VIRTUAL	The target's virtual memory has changed.
DEBUG_DATA_SPACE_PHYSICAL	The target's physical memory has changed.
DEBUG_DATA_SPACE_CONTROL	The target's control memory has changed.
DEBUG_DATA_SPACE_IO	The target's I/O ports have received input or output.
DEBUG_DATA_SPACE_MSR	The target's Model-Specific Registers (MSRs) have changed.
DEBUG_DATA_SPACE_BUS_DATA	The target's bus memory has changed.

DEBUG_CDS_REFRESH

The following table contains the possible values of *Argument*.

Value
DEBUG_CDS_REFRESH_EVALUATE
DEBUG_CDS_REFRESH_EXECUTE
DEBUG_CDS_REFRESH_EXECUTECOMMANDFILE
DEBUG_CDS_REFRESH_ADDBREAKPOINT
DEBUG_CDS_REFRESH_REMOVEBREAKPOINT
DEBUG_CDS_REFRESH_WRITEVIRTUAL
DEBUG_CDS_REFRESH_WRITEVIRTUALUNCACHED
DEBUG_CDS_REFRESH_WRITEPHYSICAL
DEBUG_CDS_REFRESH_WRITEPHYSICAL2
DEBUG_CDS_REFRESH_SETVALUE
DEBUG_CDS_REFRESH_SETVALUE2
DEBUG_CDS_REFRESH_SETSCOPE
DEBUG_CDS_REFRESH_SETSCOPEFRAMEBYINDEX
DEBUG_CDS_REFRESH_SETSCOPEFROMJITDEBUGINFO
DEBUG_CDS_REFRESH_SETSCOPEFROMSTOREDEVENT
DEBUG_CDS_REFRESH_INLINESTEP
DEBUG_CDS_REFRESH_INLINESTEP_PSEUDO

Return value

The return value is ignored by the engine unless it indicates a remote procedure call error; in this case the client, with which this **IDebugEventCallbacks** object is registered, is disabled.

Remarks

The engine calls **ChangeDebuggeeState** only if the DEBUG_EVENT_CHANGE_DEBUGGEE_STATE flag is set in the mask returned by [IDebugEventCallbacks::GetInterestMask](#).

For more information about handling events, see [Monitoring Events](#). For information about managing the target's memory, including registers and data spaces, see [Memory Access](#). For information about the target's virtual and physical memory, see [Virtual and Physical Memory](#). For information about the target's control memory, I/O ports, MSR, and bus memory, see [Other Data Spaces](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugEventCallbacks::ChangeEngineState method

The `ChangeEngineState` callback method is called by the engine when its state has changed.

Syntax

```
C++
HRESULT ChangeEngineState(
    [in] ULONG    Flags,
    [in] ULONG64 Argument
);
```

Parameters

Flags [in]

Specifies a bit-set indicating the type of changes that occurred in the engine's state. The following bit flags might be set:

Value	Description
DEBUG_CES_CURRENT_THREAD	The current thread has changed, which implies that the current target and current process might also have changed.
DEBUG_CES_EFFECTIVE_PROCESSOR	The effective processor has changed.
DEBUG_CES_BREAKPOINTS	One or more breakpoints have changed.
DEBUG_CES_CODE_LEVEL	The code interpretation level has changed.
DEBUG_CES_EXECUTION_STATUS	The execution status has changed.
DEBUG_CES_ENGINE_OPTIONS	The engine options have changed.
DEBUG_CES_LOG_FILE	The log file has been opened or closed.
DEBUG_CES_RADIX	The default radix has changed.
DEBUG_CES_EVENT_FILTERS	The event filters have changed.
DEBUG_CES_PROCESS_OPTIONS	The process options for the current process have changed.
DEBUG_CES_EXTENSIONS	Extension DLLs have been loaded or unloaded. (For more information, see Loading Debugger Extension DLLs .)
DEBUG_CES_SYSTEMS	A target has been added or removed.
DEBUG_CES_ASSEMBLY_OPTIONS	The assemble options have changed.
DEBUG_CES_EXPRESSION_SYNTAX	The default expression syntax has changed.
DEBUG_CES_TEXT_REPLACEMENTS	Text replacements have changed.

Argument [in]

Provides additional information about the change to the engine's state. If more than one bit flag is set in the *Flags* parameter, the *Argument* parameter is not used. Otherwise, the interpretation of the value of *Argument* depends on the value of *Flags*:

DEBUG_CES_CURRENT_THREAD

The value of *Argument* is the current engine thread ID or--if there is no current thread--DEBUG_ANY_ID. For more information, see [Threads and Processes](#).

DEBUG_CES_EFFECTIVE_PROCESSOR

The value of *Argument* is the type of the effective processor.

DEBUG_CES_BREAKPOINTS

The value of *Argument* is the breakpoint ID of the breakpoint that was changed or--if more than one breakpoint was changed--DEBUG_ANY_ID. For more information, see [Breakpoints](#).

DEBUG_CES_CODE_LEVEL

The value of *Argument* is the code interpretation level.

DEBUG_CES_EXECUTION_STATUS

The value of *Argument* is the execution status (as described in the [DEBUG STATUS XXX](#) topic) possibly combined with the bit flag DEBUG_STATUS_INSIDE_WAIT. DEBUG_STATUS_INSIDE_WAIT is set when a `WaitForEvent` call is pending. For more information, see [Debugging Session and Execution Model](#).

DEBUG_CES_ENGINE_OPTIONS

The value of *Argument* is the engine options.

DEBUG_CES_LOG_FILE

The value of *Argument* is TRUE if the log file was opened and FALSE if the log file was closed.

DEBUG_CES_RADIX

The value of *Argument* is the default radix.

DEBUG_CES_EVENT_FILTERS

The value of *Argument* is the index of the event filter that was changed or--if more than one event filter was changed--DEBUG_ANY_ID.

DEBUG_CES_PROCESS_OPTIONS

The value of *Argument* is the process options for the current process.

DEBUG_CES_EXTENSIONS

The value of *Argument* is zero.

DEBUG_CES_SYSTEMS

The value of *Argument* is the target ID of the target that was added or--if a target was removed--DEBUG_ANY_ID.

DEBUG_CES_ASSEMBLE_OPTIONS

The value of *Argument* is the assemble options.

DEBUG_CES_EXPRESSION_SYNTAX

The value of *Argument* is the default expression syntax.

DEBUG_CES_TEXT_REPLACEMENTS

The value of *Argument* is DEBUG_ANY_ID.

Return value

The return value is ignored by the engine unless it indicates a remote procedure call error; in this case the client, with which this **IDebugEventCallbacks** object is registered, is disabled.

Remarks

This method is only called by the engine if the DEBUG_EVENT_CHANGE_ENGINE_STATE flag is set in the mask returned by [IDebugEventCallbacks::GetInterestMask](#).

For more information about handling events, see [Monitoring Events](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugEventCallbacks::ChangeSymbolState method

The **ChangeSymbolState** callback method is called by the engine when the symbol state changes.

Syntax

```
C++
HRESULT ChangeSymbolState(
    [in] ULONG   Flags,
    [in] ULONG64 Argument
);
```

Parameters

Flags [in]

Specifies a bit-set indicating the nature of the change to the symbol state. The following bit flags might be set.

Value	Description
DEBUG_CSS_LOADS	The engine has loaded some module symbols.
DEBUG_CSS_UNLOADS	The engine has unloaded some module symbols.
DEBUG_CSS_SCOPE	The current symbol scope has changed.
DEBUG_CSS_PATHS	The executable image, source , or symbol search paths have changed.
DEBUG_CSS_SYMBOL_OPTIONS	The symbol options have changed.
DEBUG_CSS_TYPE_OPTIONS	The type options have changed.

Argument [in]

Provides additional information about the change to the symbol state. If more than one bit flag is set in the *Flags* parameter, the *Argument* parameter is not used. Otherwise, the value of *Argument* depends on the value of *Flags*:

DEBUG_CSS_LOADS

The value of *Argument* is the base location (in the target's memory address space) of the module image that the engine loaded symbols for.

DEBUG_CSS_UNLOADS

The value of *Argument* is the base location (in the target's memory address space) of the module image that the engine unloaded symbols for. If the engine unloaded symbols for more than one image, the value of *Argument* is zero.

DEBUG_CSS_SCOPE

The value of *Argument* is zero.

DEBUG_CSS_PATHS

The value of *Argument* is zero.

DEBUG_CSS_SYMBOL_OPTIONS

The value of *Argument* is the symbol options.

DEBUG_CSS_TYPE_OPTIONS

The value of *Argument* is zero.

Return value

The return value is ignored by the engine unless it indicates a remote procedure call error; in this case the client, with which this **IDebugEventCallbacks** object is registered, is disabled.

Remarks

This method is only called by the engine if the DEBUG_EVENT_CHANGE_SYMBOL_STATE flag is set in the mask returned by [IDebugEventCallbacks::GetInterestMask](#).

For more information about handling events, see [Monitoring Events](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugEventCallbacks::CreateProcess method

The **CreateProcess** callback method is called by the engine when a create-processdebugging event occurs in the target.

Syntax

C++

```
HRESULT CreateProcess(
    [in]           ULONG64 ImageFileHandle,
    [in]           ULONG64 Handle,
    [in]           ULONG64 BaseOffset,
    [in]           ULONG   ModuleSize,
    [in, optional] PCSTR   ModuleName,
    [in, optional] PCSTR   ImageName,
    [in]           ULONG   CheckSum,
    [in]           ULONG   TimeDateStamp,
    [in]           ULONG64 InitialThreadHandle,
    [in]           ULONG64 ThreadDataOffset,
    [in]           ULONG64 StartOffset
);
```

Parameters

ImageFileHandle [in]

Specifies the handle to the process's image file. If this information is not available, *ImageFileHandle* will be **NULL**.

Handle [in]

Specifies the handle to the process. This parameter corresponds to the **hProcess** field in the **CREATE_PROCESS_DEBUG_INFO** structure. If this information is not available, *ImageFileHandle* will be **NULL**.

BaseOffset [in]

Specifies the base address of the process's executable image in the target's memory address space. If this information is not available, *BaseOffset* will be **NULL**.

ModuleSize [in]

Specifies the process's executable image size in bytes. If this information is not available, *ModuleSize* will be zero.

ModuleName [in, optional]

Specifies the simplified module name that is used by the debugger engine. In most cases, this matches the image file name excluding the extension. If this information is not available, *ModuleName* will be **NULL**.

ImageName [in, optional]

Specifies the process's executable-image file name, which can include the path. If this information is not available, *ImageName* will be **NULL**.

CheckSum [in]

Specifies the checksum of the process's executable image. If this information is not available, *CheckSum* will be zero.

TimeDateStamp [in]

Specifies the time and date stamp of the process's executable-image file. If this information is not available, *TimeDateStamp* will be zero.

InitialThreadHandle [in]

Specifies the handle to the process's initial thread. This parameter corresponds to the **hThread** field in the **CREATE_PROCESS_DEBUG_INFO** structure. If this information is not available, *InitialThreadHandle* will be **NULL**.

ThreadDataOffset [in]

Specifies a block of data that the operating system maintains for this thread. The actual data in the block is operating system-specific. If this information is not available, *ThreadDataOffset* will be **NULL**.

StartOffset [in]

Specifies the starting address of the thread in the process's virtual address space. If this information is not available, *StartOffset* will be **NULL**.

Return value

This method returns a [DEBUG STATUS XXX](#) value, which indicates how the execution of the target should proceed after the engine processes this event. For details on how the engine treats this value, see [Monitoring Events](#).

Remarks

This method is only called by the engine if the DEBUG_EVENT_CREATE_PROCESS flag is set in the mask returned by [IDebugEventCallbacks::GetInterestMask](#).

For more information about handling events, see [Monitoring Events](#). For information about threads, see [Threads and Processes](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugEventCallbacks::CreateThread method

The **CreateThread** callback method is called by the engine when a create-thread debugging event occurs in the target.

Syntax

```
C++  
HRESULT CreateThread(  
    [in] ULONG64 Handle,  
    [in] ULONG64 DataOffset,  
    [in] ULONG64 StartOffset  
) ;
```

Parameters

Handle [in]

Specifies the handle for the thread whose creation caused the event. If this information is not available, *Handle* will be **NULL**.

DataOffset [in]

Specifies a block of data that the operating system maintains for this thread. The actual data in the block is operating system-specific. If the operating system does not have such a block, *DataOffset* will be **NULL**.

StartOffset [in]

Specifies the starting location in the target's virtual address space of the thread. If this information is not available, *StartOffset* will be **NULL**.

Return value

This method returns a [DEBUG STATUS XXX](#) value, which indicates how the execution of the target should proceed after the engine processes this event. For details on how the engine treats this value, see [Monitoring Events](#).

Remarks

This method is only called by the engine if the DEBUG_EVENT_CREATE_THREAD flag is set in the mask returned by [IDebugEventCallbacks::GetInterestMask](#).

For more information about handling events, see [Monitoring Events](#). For information about threads, see [Threads and Processes](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugEventCallbacks::Exception method

The **Exception** callback method is called by the engine when an *exception* debugging event occurs in the target.

Syntax

C++

```
HRESULT Exception(
    [in] PEXCEPTION_RECORD64 Exception,
    [in] ULONG           FirstChance
);
```

Parameters

Exception [in]

Specifies the nature of the exception. EXCEPTION_RECORD64 is defined in winnt.h.

FirstChance [in]

Specifies whether this exception has been previously encountered. A nonzero value means that this is the first time the exception has been encountered ("first chance"). A zero value means that the exception has already been offered to all possible handlers, and each one declined to handle it ("second chance").

Return value

This method returns a [DEBUG STATUS XXX](#) value, which indicates how the execution of the target should proceed after the engine processes this event. For details on how the engine treats this value, see [Monitoring Events](#).

Remarks

This method is only called by the engine if the DEBUG_EVENT_EXCEPTION flag is set in the mask returned by [IDebugEventCallbacks::GetInterestMask](#).

Because the structure that *Exception* points to might be deleted after this method returns, implementations of **IDebugEventCallbacks** should not access this structure after returning.

For more information about handling events, see [Monitoring Events](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

IDebugEventCallbacks::ExitProcess method

The **ExitProcess** callback method is called by the engine when an exit-processdebugging event occurs in the target.

Syntax

```
C++  
HRESULT ExitProcess(  
    [in] ULONG ExitCode  
) ;
```

Parameters

ExitCode [in]

Specifies the exit code for the process.

Return value

This method returns a [DEBUG STATUS XXX](#) value, which indicates how the execution of the target should proceed after the engine processes this event. For details on how the engine treats this value, see [Monitoring Events](#).

Remarks

This method is only called by the engine if the DEBUG_EVENT_EXIT_PROCESS flag is set in the mask returned by [IDebugEventCallbacks::GetInterestMask](#).

For more information about handling events, see [Monitoring Events](#). For information about threads, see [Threads and Processes](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugEventCallbacks::ExitThread method

The **ExitThread** callback method is called by the engine when an exit-threaddebugging event occurs in the target.

Syntax

```
C++  
HRESULT ExitThread(  
    [in] ULONG ExitCode  
) ;
```

Parameters

ExitCode [in]

Specifies the exit code for the thread.

Return value

This method returns a [DEBUG STATUS XXX](#) value, which indicates how the execution of the target should proceed after the engine processes this event. For details on how the engine treats this value, see [Monitoring Events](#).

Remarks

This method is only called by the engine if the DEBUG_EVENT_EXIT_THREAD flag is set in the mask returned by [IDebugEventCallbacks::GetInterestMask](#).

For more information about handling events, see [Monitoring Events](#). For information about threads, see [Threads and Processes](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugEventCallbacks::GetInterestMask method

The **GetInterestMask** callback method is called to determine which [events](#) the **IDebugEventCallbacks** object is interested in. The engine calls **GetInterestMask** when the object is registered with a client by using [SetEventCallbacks](#).

Syntax

```
C++
HRESULT GetInterestMask(
    [out] PULONG Mask
);
```

Parameters

Mask [out]

Receives a bitmask that indicates which events the object is interested in. The engine will call only those methods that correspond to the bit flags set by **GetInterestMask**. For a description of the bit flags and their corresponding methods, see [DEBUG_EVENT_XXX](#).

Return value

The return value **S_OK** indicates the method was successful. All other return values indicate an error occurred, in which case the **SetEventCallbacks** call will fail and the callback object will not be used nor will it receive events.

Remarks

For more information about handling events, see [Monitoring Events](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugEventCallbacks::LoadModule method

The **LoadModule** callback method is called by the engine when a module-load debugging event occurs in the target.

Syntax

```
C++
HRESULT LoadModule(
    [in]          ULONG64 ImageFileHandle,
    [in]          ULONG64 BaseOffset,
    [in]          ULONG   ModuleSize,
    [in, optional] PCSTR   ModuleName,
    [in, optional] PCSTR   ImageName,
    [in]          ULONG   CheckSum,
    [in]          ULONG   TimeStamp
);
```

Parameters

ImageFileHandle [in]

Specifies the handle to the module's image file. If this information is not available, *ImageFileHandle* will be **NULL**.

BaseOffset [in]

Specifies the base address of the module in the target's memory address space. If this information is not available, *BaseOffset* will be **NULL**.

ModuleSize [in]

Specifies the module's image size in bytes. If this information is not available, *ModuleSize* will be **NULL**.

ModuleName [in, optional]

Specifies the simplified module name that is used by the debugger engine. In most cases, this matches the image file name excluding the extension. If this information is not available, *ModuleName* will be **NULL**.

ImageName [in, optional]

Specifies the module's image file name, which can include the path. If this information is not available, *ImageName* will be **NULL**.

CheckSum [in]

Specifies the checksum of the module's image file. If this information is not available, *CheckSum* will be **NULL**.

TimeDateStamp [in]

Specifies the time and date stamp of the module's image file. If this information is not available, *TimeDateStamp* will be zero.

Return value

This method returns a [DEBUG_STATUS_XXX](#) value, which indicates how the execution of the target should proceed after the engine processes this event. For details on how the engine treats this value, see [Monitoring Events](#).

Remarks

This method is only called by the engine if the DEBUG_EVENT_LOAD_MODULE flag is set in the mask returned by [IDebugEventCallbacks::GetInterestMask](#).

After calling this method, the engine will call [IDebugEventCallbacks::ChangeSymbolState](#), with the *Flags* parameter containing the bit flag DEBUG_CSS_LOADS.

For more information about handling events, see [Monitoring Events](#).

Requirements**Target platform**

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugEventCallbacks::SessionStatus method

The **SessionStatus** callback method is called by the engine when a change occurs in the debugger session.

Syntax

```
C++  
HRESULT SessionStatus(  
    [in] ULONG Status  
) ;
```

Parameters*Status* [in]

Specifies the new status of the debugger session. The following table describes the possible values.

Value	Description
DEBUG_SESSION_ACTIVE	A debugger session has started.
DEBUG_SESSION_END_SESSION_ACTIVE_TERMINATE	The session was ended by sending DEBUG_END_ACTIVE_TERMINATE to EndSession .
DEBUG_SESSION_END_SESSION_ACTIVE_DETACH	The session was ended by sending DEBUG_END_ACTIVE_DETACH to EndSession .
DEBUG_SESSION_END_SESSION_PASSIVE	The session was ended by sending DEBUG_END_PASSIVE to EndSession .
DEBUG_SESSION_END	The target ran to completion, ending the session.

DEBUG_SESSION_REBOOT
DEBUG_SESSION_HIBERNATE
DEBUG_SESSION_FAILURE

The target computer rebooted, ending the session.
The target computer went into hibernation, ending the session.
The engine was unable to continue the session.

Return value

This method's return value is ignored by the engine.

Remarks

This method is only called by the engine if the DEBUG_EVENT_SESSION_STATUS flag is set in the mask returned by [IDebugEventCallbacks::GetInterestMask](#).

After the engine has notified all the event callbacks of the change in the session status, it will also notify any loaded [extensions](#) that export the [DebugExtensionNotify](#) callback method. The value that it passes to the extensions depends on the value of *Status*. If *Status* is DEBUG_SESSION_ACTIVE, it passes DEBUG_SESSION_ACTIVE; otherwise, it passes DEBUG_SESSION_INACTIVE.

In the DEBUG_SESSION_ACTIVE case, the engine follows the debugger session change notification with a target state change notification by calling [IDebugEventCallbacks::ChangeDebuggeeState](#) on the event callbacks and passing DEBUG_CDS_ALL in the *Flags* parameter. In all other cases, the engine precedes this notification with an engine state change notification by calling [IDebugEventCallbacks::ChangeEngineState](#) on the event callbacks and passing DEBUG_CES_EXECUTION_STATUS in the *Flags* parameter.

For more information about handling events, see [Monitoring Events](#). For information about debugger sessions, see [Debugging Session and Execution Model](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugEventCallbacks::SystemError method

The **SystemError** callback method is called by the engine when a system error occurs in the target.

Syntax

```
C++  
HRESULT SystemError(  
    [in] ULONG Error,  
    [in] ULONG Level  
) ;
```

Parameters

Error [in]

Specifies the error that caused the event.

Level [in]

Specifies the severity of the error.

Return value

This method returns a [DEBUG STATUS XXX](#) value, which indicates how the execution of the target should proceed after the engine processes this event. For details on how the engine treats this value, see [Monitoring Events](#).

Remarks

This method is only called by the engine if the DEBUG_EVENT_SYSTEM_ERROR flag is set in the mask returned by [IDebugEventCallbacks::GetInterestMask](#).

For more information about handling events, see [Monitoring Events](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugEventCallbacks::UnloadModule method

The **UnloadModule** callback method is called by the engine when a module-unload debugging event occurs in the target.

Syntax

C++

```
HRESULT UnloadModule(
    [in, optional] PCSTR    ImageBaseName,
    [in]          ULONG64   BaseOffset
);
```

Parameters

ImageBaseName [in, optional]

Specifies the name of the module's image file, which can include the path. If this information is not available, *ImageBaseName* will be **NULL**.

BaseOffset [in]

Specifies the base address of the module in the target's memory address space. If this information is not available, *BaseOffset* will be **NULL**.

Return value

This method returns a [DEBUG STATUS XXX](#) value, which indicates how the execution of the target should proceed after the engine processes this event. For details on how the engine treats this value, see [Monitoring Events](#).

Remarks

This method is only called by the engine if the DEBUG_EVENT_UNLOAD_MODULE flag is set in the mask returned by [IDebugEventCallbacks::GetInterestMask](#).

After calling this method, the engine will call [IDebugEventCallbacks::ChangeSymbolState](#), with the *Flags* parameter containing the bit flag DEBUG_CSS_UNLOADS.

For more information about handling events, see [Monitoring Events](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugEventCallbacksWide interface

Members

The **IDebugEventCallbacksWide** interface inherits from the **IUnknown** interface. **IDebugEventCallbacksWide** also has these types of members:

- [Methods](#)

Methods

The **IDebugEventCallbacksWide** interface has these methods.

Method	Description
Breakpoint	This method is called by the engine when the target issues a breakpoint exception.
ChangeDebuggeeState	This method is called by the engine when it makes or detects changes to the target.
ChangeEngineState	This method is called by the engine when its state has changed.
ChangeSymbolState	This method is called by the engine when the symbol state changes.
CreateProcess	This method is called by the engine when a create-process debugging event occurs in the target.
CreateThread	This method is called by the engine when a create-thread debugging event occurs in the target.
Exception	This method is called by the engine when an exception debugging event occurs in the target.
ExitProcess	This method is called by the engine when an exit-process debugging event occurs in the target.
ExitThread	This method is called by the engine when an exit-thread debugging event occurs in the target.

[GetInterestMask](#)
[LoadModule](#)
[SessionStatus](#)
[SystemError](#)
[UnloadModule](#)

This method is called to determine which events the **IDebugEventCallbacksWide** object is interested in.
This method is called by the engine when a module-load debugging event occurs in the target.
This method is called by the engine when a change occurs in the debugger session.
This method is called by the engine when a system error occurs in the target.
This method is called by the engine when a module-unload debugging event occurs in the target.

Requirements

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugEventCallbacksWide::Breakpoint method

The **Breakpoint** callback method is called by the engine when the target issues a breakpoint exception.

Syntax

```
C++  
HRESULT Breakpoint(  
    [in] PDEBUG_BREAKPOINT2 Bp  
>;
```

Parameters

Bp [in]

Specifies a pointer to the [IDebugBreakpoint](#) object corresponding to the breakpoint that was triggered.

Return value

This method returns a [DEBUG_STATUS_XXX](#) value, which indicates how the execution of the target should proceed after the engine processes this event. For details on how the engine treats this value, see [Monitoring Events](#).

Remarks

If the breakpoint has an associated command, the engine executes that command before calling this method.

The engine will only call this method if an [IDebugBreakpoint](#) object corresponding to the breakpoint exists in the engine, and--if the breakpoint is a private breakpoint--this [IDebugEventCallbacksWide](#) object was registered with the client that added the breakpoint.

The engine calls this method only if the DEBUG_EVENT_BREAKPOINT flag is set in the mask returned by [IDebugEventCallbacksWide::GetInterestMask](#).

Because the engine deletes the corresponding [IDebugBreakpoint](#) object when a breakpoint is removed (for example, by using [RemoveBreakpoint](#)), the value of *Bp* might be invalid after **Breakpoint** returns. Therefore, implementations of [IDebugEventCallbacksWide](#) should not access *Bp* after **Breakpoint** returns.

For more information about handling events, see [Monitoring Events](#). For information about managing breakpoints, see [Breakpoints](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugEventCallbacksWide::ChangeDebuggeeState method

The **ChangeDebuggeeState** callback method is called by the engine when it makes or detects changes to the target.

Syntax

```
C++
HRESULT ChangeDebuggeeState(
    [in] ULONG Flags,
    [in] ULONG64 Argument
);
```

Parameters

Flags [in]

Specifies the type of changes made to the target. *Flags* may take one of the following values:

Value	Description
DEBUG_CDS_ALL	A general change in the target has occurred. For example, the target has been executing, or the engine has just attached to the target.
DEBUG_CDS_REGISTERS	The processor's register for the target have changed.
DEBUG_CDS_DATA	The target's data space has changed.

Argument [in]

Provides additional information about the change in the target. The interpretation of the value of *Argument* depends on the value of *Flags*:

DEBUG_CDS_ALL

The value of *Argument* is zero.

DEBUG_CDS_REGISTERS

If a single register has changed, the value of *Argument* is the index of that register. Otherwise, the value of *Argument* is DEBUG_ANY_ID.

DEBUG_CDS_DATA

The value of *Argument* specifies which data space was changed. The following table contains the possible values of *Argument*.

Value	Description
DEBUG_DATA_SPACE_VIRTUAL	The target's virtual memory has changed.
DEBUG_DATA_SPACE_PHYSICAL	The target's physical memory has changed.
DEBUG_DATA_SPACE_CONTROL	The target's control memory has changed.
DEBUG_DATA_SPACE_IO	The target's I/O ports have received input or output.
DEBUG_DATA_SPACE_MSR	The target's Model-Specific Registers (MSRs) have changed.
DEBUG_DATA_SPACE_BUS_DATA	The target's bus memory has changed.

Return value

The return value is ignored by the engine unless it indicates a remote procedure call error; in this case the client, with which this **IDebugEventCallbacksWide** object is registered, is disabled.

Remarks

The engine calls **ChangeDebuggeeState** only if the DEBUG_EVENT_CHANGE_DEBUGGEE_STATE flag is set in the mask returned by [IDebugEventCallbacksWide::GetInterestMask](#).

For more information about handling events, see [Monitoring Events](#). For information about managing the target's memory, including registers and data spaces, see [Memory Access](#). For information about the target's virtual and physical memory, see [Virtual and Physical Memory](#). For information about the target's control memory, I/O ports, MSR, and bus memory, see [Other Data Spaces](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugEventCallbacksWide::ChangeEngineState method

The **ChangeEngineState** callback method is called by the engine when its state has changed.

Syntax

```
C++
HRESULT ChangeEngineState(
    [in] ULONG Flags,
    [in] ULONG64 Argument
);
```

Parameters

Flags [in]

Specifies a bit-set indicating the type of changes that occurred in the engine's state. The following bit flags might be set:

Value	Description
DEBUG_CES_CURRENT_THREAD	The current thread has changed, which implies that the current target and current process might also have changed.
DEBUG_CES_EFFECTIVE_PROCESSOR	The effective processor has changed.
DEBUG_CES_BREAKPOINTS	One or more breakpoints have changed.
DEBUG_CES_CODE_LEVEL	The code interpretation level has changed.
DEBUG_CES_EXECUTION_STATUS	The execution status has changed.
DEBUG_CES_ENGINE_OPTIONS	The engine options have changed.
DEBUG_CES_LOG_FILE	The log file has been opened or closed.
DEBUG_CES_RADIX	The default radix has changed.
DEBUG_CES_EVENT_FILTERS	The event filters have changed.
DEBUG_CES_PROCESS_OPTIONS	The process options for the current process have changed.
DEBUG_CES_EXTENSIONS	Extension DLLs have been loaded or unloaded. (For more information, see Loading Debugger Extension DLLs .)
DEBUG_CES_SYSTEMS	A target has been added or removed.
DEBUG_CES_ASSEMBLY_OPTIONS	The assemble options have changed.
DEBUG_CES_EXPRESSION_SYNTAX	The default expression syntax has changed.
DEBUG_CES_TEXT_REPLACEMENTS	Text replacements have changed.

Argument [in]

Provides additional information about the change to the engine's state. If more than one bit flag is set in the *Flags* parameter, the *Argument* parameter is not used. Otherwise, the interpretation of the value of *Argument* depends on the value of *Flags*:

DEBUG_CES_CURRENT_THREAD

The value of *Argument* is the current engine thread ID or--if there is no current thread--DEBUG_ANY_ID. For more information, see [Threads and Processes](#).

DEBUG_CES_EFFECTIVE_PROCESSOR

The value of *Argument* is the type of the effective processor.

DEBUG_CES_BREAKPOINTS

The value of *Argument* is the breakpoint ID of the breakpoint that was changed or--if more than one breakpoint was changed--DEBUG_ANY_ID. For more information, see [Breakpoints](#).

DEBUG_CES_CODE_LEVEL

The value of *Argument* is the code interpretation level.

DEBUG_CES_EXECUTION_STATUS

The value of *Argument* is the execution status (as described in the [DEBUG_STATUS_XXX](#) topic) possibly combined with the bit flag DEBUG_STATUS_INSIDE_WAIT. DEBUG_STATUS_INSIDE_WAIT is set when a **WaitForEvent** call is pending. For more information, see [Debugging Session and Execution Model](#).

DEBUG_CES_ENGINE_OPTIONS

The value of *Argument* is the engine options.

DEBUG_CES_LOG_FILE

The value of *Argument* is **TRUE** if the log file was opened and **FALSE** if the log file was closed.

DEBUG_CES_RADIX

The value of *Argument* is the default radix.

DEBUG_CES_EVENT_FILTERS

The value of *Argument* is the index of the event filter that was changed or--if more than one event filter was changed--DEBUG_ANY_ID.

DEBUG_CES_PROCESS_OPTIONS

The value of *Argument* is the process options for the current process.

DEBUG_CES_EXTENSIONS

The value of *Argument* is zero.

DEBUG_CES_SYSTEMS

The value of *Argument* is the target ID of the target that was added or--if a target was removed--DEBUG_ANY_ID.

DEBUG_CES_ASSEMBLE_OPTIONS

The value of *Argument* is the assemble options.

DEBUG_CES_EXPRESSION_SYNTAX

The value of *Argument* is the default expression syntax.

DEBUG_CES_TEXT_REPLACEMENTS

The value of *Argument* is DEBUG_ANY_ID.

Return value

The return value is ignored by the engine unless it indicates a remote procedure call error; in this case the client, with which this **IDebugEventCallbacksWide** object is registered, is disabled.

Remarks

This method is only called by the engine if the DEBUG_EVENT_CHANGE_ENGINE_STATE flag is set in the mask returned by [IDebugEventCallbacksWide::GetInterestMask](#).

For more information about handling events, see [Monitoring Events](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugEventCallbacksWide::ChangeSymbolState method

The **ChangeSymbolState** callback method is called by the engine when the symbol state changes.

Syntax

```
C++  
HRESULT ChangeSymbolState(  
    [in] ULONG Flags,  
    [in] ULONG64 Argument  
) ;
```

Parameters

Flags [in]

Specifies a bit-set indicating the nature of the change to the symbol state. The following bit flags might be set.

Value	Description
DEBUG_CSS_LOADS	The engine has loaded some module symbols.
DEBUG_CSS_UNLOADS	The engine has unloaded some module symbols.
DEBUG_CSS_SCOPE	The current symbol scope has changed.
DEBUG_CSS_PATHS	The executable image, source , or symbol search paths have changed.
DEBUG_CSS_SYMBOL_OPTIONS	The symbol options have changed.
DEBUG_CSS_TYPE_OPTIONS	The type options have changed.

Argument [in]

Provides additional information about the change to the symbol state. If more than one bit flag is set in the *Flags* parameter, the *Argument* parameter is not used. Otherwise, the value of *Argument* depends on the value of *Flags*:

DEBUG_CSS_LOADS

The value of *Argument* is the base location (in the target's memory address space) of the module image that the engine loaded symbols for.

DEBUG_CSS_UNLOADS

The value of *Argument* is the base location (in the target's memory address space) of the module image that the engine unloaded symbols for. If the engine unloaded symbols for more than one image, the value of *Argument* is zero.

DEBUG_CSS_SCOPE

The value of *Argument* is zero.

DEBUG_CSS_PATHS

The value of *Argument* is zero.

DEBUG_CSS_SYMBOL_OPTIONS

The value of *Argument* is the symbol options.

DEBUG_CSS_TYPE_OPTIONS

The value of *Argument* is zero.

Return value

The return value is ignored by the engine unless it indicates a remote procedure call error; in this case the client, with which this **IDebugEventCallbacksWide** object is registered, is disabled.

Remarks

This method is only called by the engine if the DEBUG_EVENT_CHANGE_SYMBOL_STATE flag is set in the mask returned by [IDebugEventCallbacksWide::GetInterestMask](#).

For more information about handling events, see [Monitoring Events](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugEventCallbacksWide::CreateProcess method

The **CreateProcess** callback method is called by the engine when a create-processdebugging event occurs in the target.

Syntax

C++

```
HRESULT CreateProcess(
    [in]          ULONG64 ImageFileHandle,
    [in]          ULONG64 Handle,
    [in]          ULONG64 BaseOffset,
    [in]          ULONG   ModuleSize,
    [in, optional] PCWSTR  ModuleName,
    [in, optional] PCWSTR  ImageName,
    [in]          ULONG   CheckSum,
    [in]          ULONG   TimeStamp,
    [in]          ULONG64 InitialThreadHandle,
    [in]          ULONG64 ThreadDataOffset,
    [in]          ULONG64 StartOffset
);
```

Parameters

ImageFileHandle [in]

Specifies the handle to the process's image file. If this information is not available, *ImageFileHandle* will be **NULL**.

Handle [in]

Specifies the handle to the process. This parameter corresponds to the **hProcess** field in the **CREATE_PROCESS_DEBUG_INFO** structure. If this information is not available, *ImageFileHandle* will be **NULL**.

BaseOffset [in]

Specifies the base address of the process's executable image in the target's memory address space. If this information is not available, *BaseOffset* will be **NULL**.

ModuleSize [in]

Specifies the process's executable image size in bytes. If this information is not available, *ModuleSize* will be zero.

ModuleName [in, optional]

Specifies the simplified module name that is used by the debugger engine. In most cases, this matches the image file name excluding the extension. If this information is not available, *ModuleName* will be **NULL**.

ImageName [in, optional]

Specifies the process's executable-image file name, which can include the path. If this information is not available, *ImageName* will be **NULL**.

CheckSum [in]

Specifies the checksum of the process's executable image. If this information is not available, *CheckSum* will be zero.

TimeDateStamp [in]

Specifies the time and date stamp of the process's executable-image file. If this information is not available, *TimeDateStamp* will be zero.

InitialThreadHandle [in]

Specifies the handle to the process's initial thread. This parameter corresponds to the **hThread** field in the **CREATE_PROCESS_DEBUG_INFO** structure. If this information is not available, *InitialThreadHandle* will be **NULL**.

ThreadDataOffset [in]

Specifies a block of data that the operating system maintains for this thread. The actual data in the block is operating system-specific. If this information is not available, *ThreadDataOffset* will be **NULL**.

StartOffset [in]

Specifies the starting address of the thread in the process's virtual address space. If this information is not available, *StartOffset* will be **NULL**.

Return value

This method returns a **DEBUG STATUS XXX** value, which indicates how the execution of the target should proceed after the engine processes this event. For details on how the engine treats this value, see [Monitoring Events](#).

Remarks

This method is only called by the engine if the DEBUG_EVENT_CREATE_PROCESS flag is set in the mask returned by [**IDebugEventCallbacksWide::GetInterestMask**](#).

For more information about handling events, see [Monitoring Events](#). For information about threads, see [Threads and Processes](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugEventCallbacksWide::CreateThread method

The **CreateThread** callback method is called by the engine when a create-thread debugging event occurs in the target.

Syntax

C++

```
HRESULT CreateThread(
    [in] ULONG64 Handle,
    [in] ULONG64 DataOffset,
    [in] ULONG64 StartOffset
);
```

Parameters

Handle [in]

Specifies the handle for the thread whose creation caused the event. If this information is not available, *Handle* will be **NULL**.

DataOffset [in]

Specifies a block of data that the operating system maintains for this thread. The actual data in the block is operating system-specific. If the operating system does not have such a block, *DataOffset* will be **NULL**.

StartOffset [in]

Specifies the starting location in the target's virtual address space of the thread. If this information is not available, *StartOffset* will be **NULL**.

Return value

This method returns a [DEBUG STATUS XXX](#) value, which indicates how the execution of the target should proceed after the engine processes this event. For details on how the engine treats this value, see [Monitoring Events](#).

Remarks

This method is only called by the engine if the DEBUG_EVENT_CREATE_THREAD flag is set in the mask returned by [IDebugEventCallbacksWide::GetInterestMask](#).

For more information about handling events, see [Monitoring Events](#). For information about threads, see [Threads and Processes](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugEventCallbacksWide::Exception method

The **Exception** callback method is called by the engine when an *exception* debugging event occurs in the target.

Syntax

C++

```
HRESULT Exception(
    [in] PEXCEPTION_RECORD64 Exception,
    [in] ULONG           FirstChance
);
```

Parameters

Exception [in]

Specifies the nature of the exception. EXCEPTION_RECORD64 is defined in Winnt.h.

FirstChance [in]

Specifies whether this exception has been previously encountered. A nonzero value means that this is the first time the exception has been encountered ("first chance"). A zero value means that the exception has already been offered to all possible handlers, and each one declined to handle it ("second chance").

Return value

This method returns a [DEBUG STATUS XXX](#) value, which indicates how the execution of the target should proceed after the engine processes this event. For details on how the engine treats this value, see [Monitoring Events](#).

Remarks

This method is only called by the engine if the DEBUG_EVENT_EXCEPTION flag is set in the mask returned by [IDebugEventCallbacksWide::GetInterestMask](#).

Because the structure that *Exception* points to might be deleted after this method returns, implementations of **IDebugEventCallbacksWide** should not access this structure after returning.

For more information about handling events, see [Monitoring Events](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

IDebugEventCallbacksWide::ExitProcess method

The **ExitProcess** callback method is called by the engine when an exit-processdebugging event occurs in the target.

Syntax

```
C++
HRESULT ExitProcess(
    [in] ULONG ExitCode
);
```

Parameters

ExitCode [in]

Specifies the exit code for the process.

Return value

This method returns a [DEBUG STATUS XXX](#) value, which indicates how the execution of the target should proceed after the engine processes this event. For details on how the engine treats this value, see [Monitoring Events](#).

Remarks

This method is only called by the engine if the DEBUG_EVENT_EXIT_PROCESS flag is set in the mask returned by [IDebugEventCallbacksWide::GetInterestMask](#).

For more information about handling events, see [Monitoring Events](#). For information about threads, see [Threads and Processes](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugEventCallbacksWide::ExitThread method

The **ExitThread** callback method is called by the engine when an exit-threaddebugging event occurs in the target.

Syntax

```
C++
HRESULT ExitThread(
    [in] ULONG ExitCode
);
```

Parameters

ExitCode [in]

Specifies the exit code for the thread.

Return value

This method returns a [DEBUG STATUS XXX](#) value, which indicates how the execution of the target should proceed after the engine processes this event. For details on how the engine treats this value, see [Monitoring Events](#).

Remarks

This method is only called by the engine if the DEBUG_EVENT_EXIT_THREAD flag is set in the mask returned by [IDebugEventCallbacksWide::GetInterestMask](#).

For more information about handling events, see [Monitoring Events](#). For information about threads, see [Threads and Processes](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugEventCallbacksWide::GetInterestMask method

The **GetInterestMask** callback method is called to determine which [events](#) the **IDebugEventCallbacksWide** object is interested in. The engine calls **GetInterestMask** when the object is registered with a client by using [SetEventCallbacks](#).

Syntax

```
C++
HRESULT GetInterestMask(
    [out] PULONG Mask
);
```

Parameters

Mask [out]

Receives a bitmask that indicates which events the object is interested in. The engine will call only those methods that correspond to the bit flags set by **GetInterestMask**. For a description of the bit flags and their corresponding methods, see [DEBUG EVENT XXX](#).

Return value

The return value `S_OK` indicates the method was successful. All other return values indicate an error occurred, in which case the **SetEventCallbacks** call will fail and the callback object will not be used nor will it receive events.

Remarks

For more information about handling events, see [Monitoring Events](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugEventCallbacksWide::LoadModule method

The **LoadModule** callback method is called by the engine when a module-load debugging event occurs in the target.

Syntax

```
C++
HRESULT LoadModule(
    [in]          ULONG64 ImageFileHandle,
    [in]          ULONG64 BaseOffset,
    [in]          ULONG   ModuleSize,
    [in, optional] PCWSTR  ModuleName,
    [in, optional] PCWSTR  ImageName,
    [in]          ULONG   CheckSum,
    [in]          ULONG   TimeDateStamp
);
```

Parameters

ImageFileHandle [in]

Specifies the handle to the module's image file. If this information is not available, *ImageFileHandle* will be **NULL**.

BaseOffset [in]

Specifies the base address of the module in the target's memory address space. If this information is not available, *BaseOffset* will be **NULL**.

ModuleSize [in]

Specifies the module's image size in bytes. If this information is not available, *ModuleSize* will be **NULL**.

ModuleName [in, optional]

Specifies the simplified module name that is used by the debugger engine. In most cases, this matches the image file name excluding the extension. If this information is not available, *ModuleName* will be **NULL**.

ImageName [in, optional]

Specifies the module's image file name, which can include the path. If this information is not available, *ImageName* will be **NULL**.

CheckSum [in]

Specifies the checksum of the module's image file. If this information is not available, *CheckSum* will be **NULL**.

TimeDateStamp [in]

Specifies the time and date stamp of the module's image file. If this information is not available, *TimeDateStamp* will be zero.

Return value

This method returns a [DEBUG_STATUS_XXX](#) value, which indicates how the execution of the target should proceed after the engine processes this event. For details on how the engine treats this value, see [Monitoring Events](#).

Remarks

This method is only called by the engine if the DEBUG_EVENT_LOAD_MODULE flag is set in the mask returned by [IDebugEventCallbacksWide::GetInterestMask](#).

After calling this method, the engine will call [IDebugEventCallbacksWide::ChangeSymbolState](#), with the *Flags* parameter containing the bit flag DEBUG_CSS_LOADS.

For more information about handling events, see [Monitoring Events](#).

Requirements**Target platform**

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugEventCallbacksWide::SessionStatus method

The **SessionStatus** callback method is called by the engine when a change occurs in the debugger session.

Syntax

```
C++  
HRESULT SessionStatus(  
    [in] ULONG Status  
) ;
```

Parameters**Status** [in]

Specifies the new status of the debugger session. The following table describes the possible values.

Value	Description
DEBUG_SESSION_ACTIVE	A debugger session has started.
DEBUG_SESSION_END_SESSION_ACTIVE_TERMINATE	The session was ended by sending DEBUG_END_ACTIVE_TERMINATE to EndSession .
DEBUG_SESSION_END_SESSION_ACTIVE_DETACH	The session was ended by sending DEBUG_END_ACTIVE_DETACH to EndSession .
DEBUG_SESSION_END_SESSION_PASSIVE	The session was ended by sending DEBUG_END_PASSIVE to EndSession .
DEBUG_SESSION_END	The target ran to completion, ending the session.
DEBUG_SESSION_REBOOT	The target computer rebooted, ending the session.
DEBUG_SESSION_HIBERNATE	The target computer went into hibernation, ending the session.
DEBUG_SESSION_FAILURE	The engine was unable to continue the session.

Return value

This method's return value is ignored by the engine.

Remarks

This method is only called by the engine if the DEBUG_EVENT_SESSION_STATUS flag is set in the mask returned by [IDebugEventCallbacksWide::GetInterestMask](#).

After the engine has notified all the event callbacks of the change in the session status, it will also notify any loaded [extensions](#) that export the [DebugExtensionNotify](#) callback method. The value that it passes to the extensions depends on the value of *Status*. If *Status* is DEBUG_SESSION_ACTIVE, it passes DEBUG_SESSION_ACTIVE; otherwise, it passes DEBUG_SESSION_INACTIVE.

In the DEBUG_SESSION_ACTIVE case, the engine follows the debugger session change notification with a target state change notification by calling [IDebugEventCallbacksWide::ChangeDebuggeeState](#) on the event callbacks and passing DEBUG_CDS_ALL in the *Flags* parameter. In all other cases, the engine precedes this notification with an engine state change notification by calling [IDebugEventCallbacksWide::ChangeEngineState](#) on the event callbacks and passing DEBUG_CES_EXECUTION_STATUS in the *Flags* parameter.

For more information about handling events, see [Monitoring Events](#). For information about debugger sessions, see [Debugging Session and Execution Model](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugEventCallbacksWide::SystemError method

The **SystemError** callback method is called by the engine when a system error occurs in the target.

Syntax

```
C++  
HRESULT SystemError(  
    [in] ULONG Error,  
    [in] ULONG Level  
) ;
```

Parameters

Error [in]

Specifies the error that caused the event.

Level [in]

Specifies the severity of the error.

Return value

This method returns a [DEBUG STATUS XXX](#) value, which indicates how the execution of the target should proceed after the engine processes this event. For details on how the engine treats this value, see [Monitoring Events](#).

Remarks

This method is only called by the engine if the DEBUG_EVENT_SYSTEM_ERROR flag is set in the mask returned by [IDebugEventCallbacksWide::GetInterestMask](#).

For more information about handling events, see [Monitoring Events](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugEventCallbacksWide::UnloadModule method

The **UnloadModule** callback method is called by the engine when a module-unload debugging event occurs in the target.

Syntax

```
C++  
HRESULT UnloadModule(  
    [in, optional] PCWSTR ImageBaseName,  
    [in]           ULONG64 BaseOffset  
) ;
```

Parameters

ImageBaseName [in, optional]

Specifies the name of the module's image file, which can include the path. If this information is not available, *ImageBaseName* will be **NULL**.

BaseOffset [in]

Specifies the base address of the module in the target's memory address space. If this information is not available, *BaseOffset* will be **NULL**.

Return value

This method returns a [DEBUG STATUS XXX](#) value, which indicates how the execution of the target should proceed after the engine processes this event. For details on how the engine treats this value, see [Monitoring Events](#).

Remarks

This method is only called by the engine if the DEBUG_EVENT_UNLOAD_MODULE flag is set in the mask returned by [IDebugEventCallbacksWide::GetInterestMask](#).

After calling this method, the engine will call [IDebugEventCallbacksWide::ChangeSymbolState](#), with the *Flags* parameter containing the bit flag DEBUG_CSS_UNLOADS.

For more information about handling events, see [Monitoring Events](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

IDebugInputCallbacks interface

Members

The **IDebugInputCallbacks** interface inherits from the **IUnknown** interface. **IDebugInputCallbacks** also has these types of members:

- [Methods](#)

Methods

The **IDebugInputCallbacks** interface has these methods.

Method	Description
EndInput	This method is called by the engine to indicate that it is no longer waiting for input.
StartInput	This method is called by the engine to indicate that it is waiting for a line of input.

Requirements

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugInputCallbacks::EndInput method

The **EndInput** callback method is called by the engine to indicate that it is no longer waiting for input.

Syntax

```
C++
HRESULT EndInput();
```

Parameters

This method has no parameters.

Return value

This method's return value is ignored by the engine.

Remarks

Even if the engine has not called [IDebugInputCallbacks::StartInput](#) for this [IDebugInputCallbacks](#) object, the engine will call **EndInput** if another [IDebugInputCallbacks](#) object returned an error from the [IDebugInputCallbacks::StartInput](#) method.

For more information about debugger engine input, see [Input and Output](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugInputCallbacks::StartInput method

The **StartInput** callback method is called by the engine to indicate that it is waiting for a line of input.

Syntax

```
C++
HRESULT StartInput(
    [in] ULONG BufferSize
);
```

Parameters

BufferSize [in]

Specifies the number of characters requested. Any input longer than this size will be truncated.

Return value

The return value is ignored by the engine unless it indicates a remote procedure call error; in this case the client, with which this [IDebugEventCallbacks](#) object is registered, is disabled.

Remarks

This method indicates that the engine is waiting for a line of input from any client. This can occur if, for example, the [Input](#) method was called on a client.

After calling this method, the engine waits until it receives some input. When it does receive input, it calls [IDebugInputCallbacks::EndInput](#) to inform all the [IDebugInputCallbacks](#) objects that are registered with clients that it is no longer waiting for input.

The [IDebugInputCallbacks](#) object can provide the engine with a line of input by calling either the [ReturnInput](#) or [ReturnInputWide](#) methods.

For more information about debugger engine input, see [Input and Output](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugOutputCallbacks interface

Members

The **IDebugOutputCallbacks** interface inherits from the **IUnknown** interface. **IDebugOutputCallbacks** also has these types of members:

- [Methods](#)

Methods

The **IDebugOutputCallbacks** interface has these methods.

Method	Description
Output	This method is called by the engine to send output from the client to the IDebugOutputCallbacks object that is registered with the client.

Requirements

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugOutputCallbacksWide](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugOutputCallbacks::Output method

The **Output** callback method is called by the engine to send output from the client to the **IDebugOutputCallbacks** object that is registered with the client.

Syntax

```
C++
HRESULT Output(
    [in] ULONG Mask,
    [in] PCSTR Text
);
```

Parameters

Mask [in]

Specifies the [DEBUG_OUTPUT_XXX](#) bit flags that indicate the nature of the output.

Text [in]

Specifies the output that is being sent.

Return value

The return value is ignored by the engine unless it indicates a remote procedure call error; in this case the client, with which this **IDebugEventCallbacks** object is registered, is disabled.

Remarks

The engine calls this method only if the supplied value of *Mask* is allowed by the client's output control.

For more information about debugger engine output, see [Input and Output](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugOutputCallbacksWide interface

Members

The **IDebugOutputCallbacksWide** interface inherits from the **IUnknown** interface. **IDebugOutputCallbacksWide** also has these types of members:

- [Methods](#)

Methods

The **IDebugOutputCallbacksWide** interface has these methods.

Method	Description
Output	This method is called by the engine to send output from the client to the IDebugOutputCallbacksWide object that is registered with the client.

Requirements

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugOutputCallbacks](#)

IDebugOutputCallbacksWide::Output method

The **Output** callback method is called by the engine to send output from the client to the **IDebugOutputCallbacksWide** object that is registered with the client.

Syntax

```
C++
HRESULT Output(
    [in] ULONG Mask,
    [in] PCWSTR Text
);
```

Parameters

Mask [in]

Specifies the [DEBUG_OUTPUT_XXX](#) bit flags that indicate the nature of the output.

Text [in]

Specifies the output that is being sent.

Return value

The return value is ignored by the engine unless it indicates a remote procedure call error; in this case the client, with which this **IDebugEventCallbacksWide** object is registered, is disabled.

Remarks

The engine calls this method only if the supplied value of *Mask* is allowed by the client's output control.

For more information about debugger engine output, see [Input and Output](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

Other Debug Engine Interfaces

This section covers the following interfaces:

- [IDebugBreakpoint](#)
- [IDebugBreakpoint2](#)
- [IDebugSymbolGroup](#)
- [IDebugSymbolGroup2](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugBreakpoint interface

Members

The **IDebugBreakpoint** interface inherits from the **IUnknown** interface. **IDebugBreakpoint** also has these types of members:

- [Methods](#)

Methods

The **IDebugBreakpoint** interface has these methods.

Method	Description
AddFlags	Adds flags to a breakpoint.
GetAdder	Returns the client that owns the breakpoint.
GetCommand	Returns the command string that is executed when a breakpoint is triggered.
GetCurrentPassCount	Returns the remaining number of times that the target must reach the breakpoint location before the breakpoint is triggered.
GetDataParameters	Returns the parameters for a processor breakpoint.
GetFlags	Returns the flags for a breakpoint.
GetId	Returns a breakpoint ID, which is the engine's unique identifier for a breakpoint.
GetMatchThreadId	Returns the engine thread ID of the thread that can trigger a breakpoint.
GetOffset	Returns the location that triggers a breakpoint.
GetOffsetExpression	Returns the expression string that evaluates to the location that triggers a breakpoint.
GetParameters	Returns the parameters for a breakpoint.
GetPassCount	Returns the number of times that the target was originally required to reach the breakpoint location before the breakpoint is triggered.
GetType	Returns the type of the breakpoint and the type of the processor that a breakpoint is set for.
RemoveFlags	Removes flags from a breakpoint.
SetCommand	Sets the command that is executed when a breakpoint is triggered.
SetDataParameters	Sets the parameters for a processor breakpoint.
SetFlags	Sets the flags for a breakpoint.
SetMatchThreadId	Sets the engine thread ID of the thread that can trigger a breakpoint.
SetOffset	Sets the location that triggers a breakpoint.
SetOffsetExpression	Sets an expression string that evaluates to the location that triggers a breakpoint.
SetPassCount	Sets the number of times that the target must reach the breakpoint location before the breakpoint is triggered.

Remarks

Although **IDebugBreakpoint** implements the **IUnknown** interface, the **IUnknown::AddRef** and **IUnknown::Release** methods are not used to control the lifetime of the breakpoint. Instead, an **IDebugBreakpoint** object is deleted after the method [RemoveBreakpoint](#) is called.

Requirements

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugBreakpoint2](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugBreakpoint::AddFlags method

The **AddFlags** method adds flags to a [breakpoint](#).

Syntax

```
C++  
HRESULT AddFlags(  
    [in] ULONG Flags  
) ;
```

Parameters

Flags [in]

Additional flags to add to the breakpoint. *Flags* is a bit field that is combined together with the existing flags by using a bitwise OR. For more information about the flag bit field and an explanation of each flag, see [Controlling Breakpoint Flags and Parameters](#). You cannot modify the DEBUG_BREAKPOINT_DEFERRED flag in the [engine](#). This bit in *Flags* must always be zero.

Return value

Return code	Description
S_OK	The method was successful.

This method can also return error values. For more information, see [Return Values](#).

Remarks

For more information about breakpoint properties, see [Controlling Breakpoint Flags and Parameters](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugBreakpoint::GetAdder method

The **GetAdder** method returns the client that owns the breakpoint.

Syntax

```
C++  
HRESULT GetAdder(  
    [out] PDEBUG_CLIENT *Adder  
) ;
```

Parameters

Adder [out]

An [IDebugClient](#) interface pointer to the client object that added the breakpoint.

Return value

Return code	Description
S_OK	The method was successful.

This method can also return error values. For more information, see [Return Values](#).

Remarks

The client that owns the breakpoint is the client that created the breakpoint by using the [AddBreakpoint](#) method. A breakpoint might not have an owner. If a breakpoint does not have an owner, *Adder* is set to **NULL**.

For more information about how to use breakpoints, see [Using Breakpoints](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugBreakpoint::GetCommand method

The **GetCommand** method returns the command string that is executed when a breakpoint is triggered.

Syntax

C++

```
HRESULT GetCommand(
    [out, optional] PSTR    Buffer,
    [in]          ULONG   BufferSize,
    [out, optional] PULONG CommandSize
);
```

Parameters

Buffer [out, optional]

The command string that is executed when the breakpoint is triggered. If *Buffer* is **NULL**, this information is not returned.

BufferSize [in]

The size, in characters, of the buffer that *Buffer* points to.

CommandSize [out, optional]

The size of the command string. If *CommandSize* is **NULL**, this information is not returned.

Return value

Return code	Description
S_OK	The method was successful.
S_FALSE	The method was successful, but the buffer was not large enough to hold the command string and so the command string was truncated to fit.

This method can also return error values. For more information, see [Return Values](#).

Remarks

The command string is a list of debugger commands that are separated by semicolons. These commands are executed every time that the breakpoint is triggered. The commands are executed before the engine informs any event callbacks that the breakpoint has been triggered.

The [GetParameters](#) method also returns the size of the breakpoint's command, *CommandSize*.

For more information about breakpoint properties, see [Controlling Breakpoint Flags and Parameters](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugBreakpoint::GetCurrentPassCount method

The **GetCurrentPassCount** method returns the remaining number of times that the target must reach the breakpoint location before the breakpoint is triggered.

Syntax

C++

```
HRESULT GetCurrentPassCount(
    [out] PULONG Count
);
```

Parameters

Count [out]

The remaining number of times that the target must hit the breakpoint before it is triggered. The number of times that the target must pass the breakpoint without triggering it is the value that is returned to *Count*, minus one.

Return value

Return code	Description
S_OK	The method was successful.

This method can also return error values. For more information, see [Return Values](#).

Remarks

The **GetPassCount** method returns the number of hits that were originally required to trigger the breakpoint. **GetCurrentPassCount** returns the number of hits that still must occur to trigger the breakpoint. For example, if a breakpoint was created with a pass count of 20, and there have been 5 passes so far, **GetPassCount** returns 20 and **GetCurrentPassCount** returns 15.

After the target has hit the breakpoint enough times to trigger it, the breakpoint is triggered every time that it is hit, unless **SetPassCount** is called again. You can also call **SetPassCount** to change the pass count before the breakpoint has been triggered. This call resets the original pass count and the remaining pass count.

If the debugger executes the code at the breakpoint location while stepping through the code, this execution does not contribute to the number of times that remain before the breakpoint is triggered.

The [GetParameters](#) method also returns the information that is returned in *Count*.

For more information about breakpoint properties, see [Controlling Breakpoint Flags and Parameters](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugBreakpoint::GetDataParameters method

The **GetDataParameters** method returns the parameters for a processor breakpoint.

Syntax

```
C++
HRESULT GetDataParameters(
    [out] PULONG Size,
    [out] PULONG AccessType
);
```

Parameters

Size [out]

The size, in bytes, of the memory block whose access triggers the breakpoint. For more information about restrictions on the value of *Size* based on the processor type, see [Valid Parameters for Processor Breakpoints](#).

AccessType [out]

The type of access that triggers the breakpoint. For a list of possible values, see [Valid Parameters for Processor Breakpoints](#).

Return value

	Return code	Description
S_OK		The method was successful.
E_NOINTERFACE		The breakpoint is not a processor breakpoint. For more information about the breakpoint type, see GetType .

This method can also return other error values. For more information, see [Return Values](#).

Remarks

The [GetParameters](#) method also returns the information that is returned in *Size* and *AccessType*.

For more information about breakpoint properties, see [Controlling Breakpoint Flags and Parameters](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugBreakpoint::GetFlags method

The [GetFlags](#) method returns the flags for a breakpoint.

Syntax

```
C++
HRESULT GetFlags(
    [out] PULONG Flags
);
```

Parameters

Flags [out]

The breakpoint's flags. For more information about the flag bit field and an explanation of each flag, see [Controlling Breakpoint Flags and Parameters](#).

Return value

Return code	Description
S_OK	The method was successful.

This method can also return error values. For more information, see [Return Values](#).

Remarks

The [GetParameters](#) method also returns the breakpoint's flags.

For more information about breakpoint properties, see [Controlling Breakpoint Flags and Parameters](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugBreakpoint::GetId method

The **GetId** method returns a breakpoint ID, which is the engine's unique identifier for a breakpoint.

Syntax

```
C++  
HRESULT GetId(  
    [out] PULONG id  
) ;
```

Parameters

Id [out]

The breakpoint ID.

Return value

Return code	Description
S_OK	The method was successful.

This method can also return error values. For more information, see [Return Values](#).

Remarks

The breakpoint ID remains fixed as long as the breakpoint exists. However, after the breakpoint has been removed, you can use its ID for another breakpoint.

The [GetParameters](#) method also returns the breakpoint ID.

For more information about how to use breakpoints, see [Using Breakpoints](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugBreakpoint::GetMatchThreadId method

The **GetMatchThreadId** method returns the engine thread ID of the thread that can trigger a breakpoint.

Syntax

```
C++  
HRESULT GetMatchThreadId(  
    [out] PULONG id  
) ;
```

Parameters

***Id* [out]**

The engine thread ID of the thread that can trigger this breakpoint.

Return value

Return code	Description
S_OK	The method was successful.
E_NOINTERFACE	No specific thread has been set for this breakpoint. Any thread can trigger the breakpoint.

This method can also return other error values. For more information, see [Return Values](#).

Remarks

If you have set a thread for the breakpoint, the breakpoint can be triggered only if that thread hits the breakpoint. If you have not set a thread, any thread can trigger the breakpoint and *Id* receives **NULL**.

The [GetParameters](#) method also returns the engine thread ID of the thread that can trigger the breakpoint.

For more information about breakpoint properties, see [Controlling Breakpoint Flags and Parameters](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugBreakpoint::GetOffset method

The **GetOffset** method returns the location that triggers a breakpoint.

Syntax

```
C++
HRESULT GetOffset(
    [out] PULONG64 Offset
);
```

Parameters

***Offset* [out]**

The location on the target that triggers the breakpoint.

Return value

Return code	Description
S_OK	The method was successful.
E_NOINTERFACE	The breakpoint is deferred and does not currently specify a location in the target's memory address space. To determine the breakpoint location in this case, call GetOffsetExpression .

This method can also return other error values. For more information, see [Return Values](#).

Remarks

The [GetParameters](#) method also returns the location that triggers a breakpoint.

For more information about how to use breakpoints, see [Using Breakpoints](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugBreakpoint::GetOffsetExpression method

The **GetOffsetExpression** methods return the expression string that evaluates to the location that triggers a breakpoint.

Syntax

C++

```
HRESULT GetOffsetExpression(
    [out, optional] PSTR    Buffer,
    [in]          ULONG   BufferSize,
    [out, optional] PULONG ExpressionSize
);
```

Parameters

Buffer [out, optional]

The expression string that evaluates to the location on the target that triggers the breakpoint. If *Buffer* is **NULL**, this information is not returned.

BufferSize [in]

The size, in characters, of the buffer that *Buffer* points to.

ExpressionSize [out, optional]

The size, in characters, of the expression string. If *ExpressionSize* is **NULL**, this information is not returned.

Return value

Return code	Description
S_OK	The method was successful.
S_FALSE	The method was successful, but the buffer was not large enough to hold the expression string and so the string was truncated to fit.

This method can also return error values. For more information, see [Return Values](#).

Remarks

The expression is evaluated every time that a module is loaded or unloaded. If the debugger cannot evaluate the expression (for example, if the expression contains a symbol that cannot be interpreted), the breakpoint is flagged as deferred. (For more information about deferred breakpoints, see [Controlling Breakpoint Flags and Parameters](#).)

The [GetParameters](#) method also returns the size of the expression string that specifies the location that triggers the breakpoint, *ExpressionSize*.

For more information about how to use breakpoints, see [Using Breakpoints](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugBreakpoint::GetParameters method

The **GetParameters** method returns the parameters for a breakpoint.

Syntax

C++

```
HRESULT GetParameters(
    [out] PDEBUG_BREAKPOINT_PARAMETERS Params
);
```

Parameters

Params [out]

The breakpoint's parameters. For more information about the parameters, see [DEBUG_BREAKPOINT_PARAMETERS](#).

Return value

Return code	Description
S_OK	The method was successful.

This method can also return error values. For more information, see [Return Values](#).

Remarks

The **GetParameters** method is a convenience method that returns most of the parameters that the other [IDebugBreakpoint](#) methods return.

For a list of the parameters and flags that this method retrieves, and for other ways to read and write these parameters and flags, see [Controlling Breakpoint Flags and Parameters](#) and [Using Breakpoints](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugBreakpoint::GetPassCount method

The **GetPassCount** method returns the number of times that the target was originally required to reach the breakpoint location before the breakpoint is triggered.

Syntax

```
C++
HRESULT GetPassCount(
    [out] PULONG Count
);
```

Parameters

Count [out]

The number of times that the target was originally required to hit the breakpoint before it is triggered. The number of times that the target was originally required to pass the breakpoint without triggering it is the value that is returned to *Count*, minus one.

Return value

Return code	Description
S_OK	The method was successful.

This method can also return error values. For more information, see [Return Values](#).

Remarks

The **GetPassCount** method returns the number of hits that were originally required to trigger the breakpoint. The **GetCurrentPassCount** method returns the number of hits that still must occur to trigger the breakpoint. For example, if a breakpoint was created with a pass count of 20, and there have been 5 passes so far, this method **GetPassCount** returns 20 and **GetCurrentPassCount** returns 15.

After the target has hit the breakpoint enough times to trigger it, the breakpoint is triggered every time that it is hit, unless you call [SetPassCount](#). You can also call [SetPassCount](#) to change the pass count before the breakpoint has been triggered. This call resets the original pass count and the remaining pass count.

If the debugger executes the code at the breakpoint location while stepping through the code, this execution does not contribute to the number of times that remain before the breakpoint is triggered.

The [GetParameters](#) method also returns the information that is returned in *Count*.

For more information about breakpoint properties, see [Controlling Breakpoint Flags and Parameters](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugBreakpoint::GetType method

The **GetType** method returns the type of the breakpoint and the type of the processor that a breakpoint is set for.

Syntax

```
C++  
HRESULT GetType(  
    [out] PULONG BreakType,  
    [out] PULONG ProcType  
) ;
```

Parameters

BreakType [out]

The type of the breakpoint. The type can be one of the following values.

Value	Description
DEBUG_BREAKPOINT_CODE	Software breakpoint
DEBUG_BREAKPOINT_DATA	Processor breakpoint

ProcType [out]

The type of the processor that the breakpoint is set for.

Return value

Return code	Description
S_OK	The method was successful.

This method can also return error values. For more information, see [Return Values](#).

Remarks

If changes are made to the breakpoint, the processor type might change.

The [GetParameters](#) method also returns the information that is returned in *BreakType* and *ProcType*.

For more information about breakpoint types, see [Breakpoints](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugBreakpoint::RemoveFlags method

The **RemoveFlags** method removes flags from a breakpoint.

Syntax

```
C++  
HRESULT RemoveFlags(  
    [in] ULONG Flags  
) ;
```

Parameters

Flags [in]

Flags to remove from the breakpoint. *Flags* is a bit field. The new value of the flags in the engine is the old value and not the value of *Flags*. For more information about the flag bit field and an explanation of each flag, see [Controlling Breakpoint Flags and Parameters](#). You cannot modify the DEBUG_BREAKPOINT_DEFERRED flag in the engine. This bit in *Flags* must always be zero.

Return value

`RemoveFlags` might return one of the following values:

Return code	Description
S_OK	The method was successful.

This method can also return error values. For more information, see [Return Values](#).

Remarks

For more information about breakpoint properties, see [Controlling Breakpoint Flags and Parameters](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugBreakpoint::SetCommand method

The `SetCommand` method sets the command that is executed when a breakpoint is triggered.

Syntax

```
C++  
HRESULT SetCommand(  
    [in] PCSTR Command  
) ;
```

Parameters

Command [in]

The command string that is executed when the breakpoint is triggered.

Return value

Return code	Description
S_OK	The method was successful.

This method can also return error values. For more information, see [Return Values](#).

Remarks

The command string is a list of debugger commands that are separated by semicolons. These commands are executed every time that the breakpoint is triggered. The commands are executed before the engine informs any event callbacks that the breakpoint has been triggered.

If the command string includes an execution command such as **G (Go)**, this command should be the last command in the *Command* string. If a command causes the target to resume execution, the rest of the command string is ignored.

For more information about breakpoint properties, see [Controlling Breakpoint Flags and Parameters](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugBreakpoint::SetDataParameters method

The **SetDataParameters** method sets the parameters for a processor breakpoint.

Syntax

```
C++
HRESULT SetDataParameters(
    [in] ULONG Size,
    [in] ULONG AccessType
);
```

Parameters

Size [in]

The size, in bytes, of the memory block whose access triggers the breakpoint. For more information about restrictions on the value of *Size* based on the processor type, see [Valid Parameters for Processor Breakpoints](#).

AccessType [in]

The type of access that triggers the breakpoint. For a list of possible value, see [Valid Parameters for Processor Breakpoints](#).

Return value

Return code	Description
S_OK	The method was successful.
E_NOINTERFACE	The breakpoint is not a processor breakpoint. For more information about the breakpoint type, see GetType .

This method can also return other error values. For more information, see [Return Values](#).

Remarks

For more information about breakpoint properties, see [Controlling Breakpoint Flags and Parameters](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugBreakpoint::SetFlags method

The **SetFlags** method sets the flags for a breakpoint.

Syntax

```
C++
HRESULT SetFlags(
    [in] ULONG Flags
);
```

Parameters

Flags [in]

The new flags for the breakpoint. *Flags* is a bit field. It replaces the existing flag bits. For more information about the flag bit field and an explanation of each flag, see [Controlling Breakpoint Flags and Parameters](#). You cannot change the DEBUG_BREAKPOINT_DEFERRED flag in the engine. This bit in *Flags* must always be zero.

Return value

Return code	Description
S_OK	The method was successful.

This method can also return error values. For more information, see [Return Values](#).

Remarks

For more information about breakpoint properties, see [Controlling Breakpoint Flags and Parameters](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugBreakpoint::SetMatchThreadId method

The **SetMatchThreadId** method sets the engine thread ID of the thread that can trigger a breakpoint.

Syntax

```
C++
HRESULT SetMatchThreadId(
    [in] ULONG Thread
);
```

Parameters

Thread [in]

The engine thread ID of the thread that can trigger this breakpoint.

Return value

Return code	Description
S_OK	The method was successful.
E_NOINTERFACE	The thread that <i>Thread</i> specifies could not be found.
E_INVALIDARG	The target is in a kernel and the breakpoint is a processor breakpoint. Processor breakpoints cannot be limited to threads in kernel mode.

This method can also return other error values. For more information, see [Return Values](#).

Remarks

If you have set a thread for the breakpoint, the breakpoint can be triggered only if that thread hits the breakpoint. If you have not set a thread, any thread can trigger the breakpoint.

If you have set a thread, you can remove the setting by setting *Id* to DEBUG_ANY_ID.

For more information about breakpoint properties, see [Controlling Breakpoint Flags and Parameters](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugBreakpoint::SetOffset method

The **SetOffset** method sets the location that triggers a breakpoint.

Syntax

```
C++  
HRESULT SetOffset(  
    [in] ULONG64 Offset  
) ;
```

Parameters

Offset [in]

The location on the target that triggers the breakpoint.

Return value

Return code	Description
S_OK	The method was successful.
E_UNEXPECTED	The breakpoint is deferred.

This method can also return other error values. For more information, see [Return Values](#).

Remarks

For more information about how to use breakpoints, see [Using Breakpoints](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugBreakpoint::SetOffsetExpression method

The **SetOffsetExpression** methods set an expression string that evaluates to the location that triggers a breakpoint.

Syntax

```
C++  
HRESULT SetOffsetExpression(  
    [in] PCSTR Expression  
) ;
```

Parameters

Expression [in]

The expression string that evaluates to the location on the target that triggers the breakpoint. If the engine cannot evaluate the expression (for example, if the expression contains a symbol that cannot be interpreted), the breakpoint is flagged as deferred. (For more information about deferred breakpoints, see [Controlling Breakpoint Flags and Parameters](#).) For more information about the expression syntax, see [Using Breakpoints](#).

Return value

Return code	Description
S_OK	The method was successful.

This method can also return error values. For more information, see [Return Values](#).

Remarks

For more information about how to use breakpoints, see [Using Breakpoints](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugBreakpoint::SetPassCount method

The **SetPassCount** method sets the number of times that the target must reach the breakpoint location before the breakpoint is triggered.

Syntax

```
C++  
HRESULT SetPassCount(  
    [in] ULONG Count  
) ;
```

Parameters

Count [in]

The number of times that the target must hit the breakpoint before it is triggered. The number of times the target must pass the breakpoint without triggering it is the value of *Count*, minus one.

Return value

Return code	Description
S_OK	The method was successful.

This method can also return error values. For more information, see [Return Values](#).

Remarks

Every time that the **SetPassCount** method is called, the number of times that the target must reach the breakpoint location before the breakpoint is triggered is reset.

After the target has hit the breakpoint enough times to trigger the breakpoint, the breakpoint is triggered every time that it is hit, unless **SetPassCount** is called again.

If the debugger executes the code at the breakpoint location while stepping through the code, this execution does not contribute to the number of times that remain before the breakpoint is triggered.

For more information about breakpoint properties, see [Controlling Breakpoint Flags and Parameters](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugBreakpoint2 interface

Members

The **IDebugBreakpoint2** interface inherits from [IDebugBreakpoint](#). **IDebugBreakpoint2** also has these types of members:

- [Methods](#)

Methods

The **IDebugBreakpoint2** interface has these methods.

Method	Description
GetCommandWide	Returns the command string that is executed when a breakpoint is triggered.
GetOffsetExpressionWide	Returns the expression string that evaluates to the location that triggers a breakpoint.
SetCommandWide	Sets the command that is executed when a breakpoint is triggered.
SetOffsetExpressionWide	Sets an expression string that evaluates to the location that triggers a breakpoint.

Requirements

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugBreakpoint](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugBreakpoint2::GetCommandWide method

The **GetCommand** method returns the command string that is executed when a breakpoint is triggered.

Syntax

```
C++  
HRESULT GetCommandWide(  
    [out, optional] PWSTR Buffer,  
    [in]          ULONG BufferSize,  
    [out, optional] PULONG CommandSize  
) ;
```

Parameters

Buffer [out, optional]

The command string that is executed when the breakpoint is triggered. If *Buffer* is **NULL**, this information is not returned.

BufferSize [in]

The size, in characters, of the buffer that *Buffer* points to.

CommandSize [out, optional]

The size of the command string. If *CommandSize* is **NULL**, this information is not returned.

Return value

Return code	Description
S_OK	The method was successful.
S_FALSE	The method was successful, but the buffer was not large enough to hold the command string and so the command string was truncated to fit.

This method can also return error values. For more information, see [Return Values](#).

Remarks

The command string is a list of debugger commands that are separated by semicolons. These commands are executed every time that the breakpoint is triggered. The commands are executed before the engine informs any event callbacks that the breakpoint has been triggered.

The [GetParameters](#) method also returns the size of the breakpoint's command, *CommandSize*.

For more information about breakpoint properties, see [Controlling Breakpoint Flags and Parameters](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugBreakpoint2::GetOffsetExpressionWide method

The **GetOffsetExpressionWide** method returns the expression string that evaluates to the location that triggers a breakpoint.

Syntax

C++

```
HRESULT GetOffsetExpressionWide(
    [out, optional] PWSTR Buffer,
    [in]          ULONG   BufferSize,
    [out, optional] PULONG ExpressionSize
);
```

Parameters

Buffer [out, optional]

The expression string that evaluates to the location on the target that triggers the breakpoint. If *Buffer* is **NULL**, this information is not returned.

BufferSize [in]

The size, in characters, of the buffer that *Buffer* points to.

ExpressionSize [out, optional]

The size, in characters, of the expression string. If *ExpressionSize* is **NULL**, this information is not returned.

Return value

Return code	Description
S_OK	The method was successful.
S_FALSE	The method was successful, but the buffer was not large enough to hold the expression string and so the string was truncated to fit.

This method can also return error values. For more information, see [Return Values](#).

Remarks

The expression is evaluated every time that a module is loaded or unloaded. If the debugger cannot evaluate the expression (for example, if the expression contains a symbol that cannot be interpreted), the breakpoint is flagged as deferred. (For more information about deferred breakpoints, see [Controlling Breakpoint Flags and Parameters](#).)

The [GetParameters](#) method also returns the size of the expression string that specifies the location that triggers the breakpoint, *ExpressionSize*.

For more information about how to use breakpoints, see [Using Breakpoints](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugBreakpoint2::SetCommandWide method

The **SetCommandWide** method sets the command that is executed when a breakpoint is triggered.

Syntax

```
C++  
HRESULT SetCommandWide(  
    [in] PCWSTR Command  
) ;
```

Parameters

Command [in]

The command string that is executed when the breakpoint is triggered.

Return value

SetCommandWide might return one of the following values:

Return code	Description
S_OK	The method was successful.

Remarks

The command string is a list of debugger commands that are separated by semicolons. These commands are executed every time that the breakpoint is triggered. The commands are executed before the engine informs any event callbacks that the breakpoint has been triggered.

If the command string includes an execution command such as **G (Go)**, this command should be the last command in the *Command* string. If a command causes the target to resume execution, the rest of the command string is ignored.

For more information about breakpoint properties, see [Controlling Breakpoint Flags and Parameters](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugBreakpoint2::SetOffsetExpressionWide method

The **SetOffsetExpressionWide** methods set an expression string that evaluates to the location that triggers a breakpoint.

Syntax

```
C++  
HRESULT SetOffsetExpressionWide(  
    [in] PCWSTR Expression  
) ;
```

Parameters

Expression [in]

The expression string that evaluates to the location on the target that triggers the breakpoint. If the engine cannot evaluate the expression (for example, if the expression contains a symbol that cannot be interpreted), the breakpoint is flagged as deferred. (For more information about deferred breakpoints, see [Controlling Breakpoint Flags and Parameters](#).) For more information about the expression syntax, see [Using Breakpoints](#).

Return value

This method might return one of the following values:

Return code	Description
S_OK	The method was successful.

Remarks

For more information about how to use breakpoints, see [Using Breakpoints](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugSymbolGroup interface

Members

The **IDebugSymbolGroup** interface inherits from the **IUnknown** interface. **IDebugSymbolGroup** also has these types of members:

- [Methods](#)

Methods

The **IDebugSymbolGroup** interface has these methods.

Method	Description
AddSymbol	Adds a symbol to a symbol group.
ExpandSymbol	Adds or removes the children of a symbol from a symbol group.
GetNumberSymbols	Returns the number of symbols that are contained in a symbol group.
GetSymbolName	Returns the name of a symbol in a symbol group.
GetSymbolParameters	Returns the symbol parameters that describe the specified symbols in a symbol group.
OutputAsType	Changes the type of a symbol in a symbol group. The symbol's entry is updated to represent the new type.
OutputSymbols	Prints the specified symbols to the debugger console.
RemoveSymbolByIndex	Removes the specified symbol from a symbol group.
RemoveSymbolByName	Removes the specified symbol from a symbol group.
WriteSymbol	Sets the value of the specified symbol.

Requirements

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugSymbolGroup2](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugSymbolGroup::AddSymbol method

The **AddSymbol** method adds a symbol to a [symbol group](#).

Syntax

```
C++
HRESULT AddSymbol(
    [in]          PCSTR  Name,
    [in, out]     PULONG Index
);
```

Parameters

Name [in]

The symbol's name. *Name* is examined as an expression to determine the symbol's [type](#). This expression can include pointer, array, and structure dereferencing (for example, `*my_pointer`, `my_array[1]`, or `my_struct.some_field`).

Index [in, out]

The index of the entry in the symbol group. When you are calling [AddSymbol](#) or [AddSymbolWide](#), *Index* should point to the index of the symbol that you want. Or, if *Index* points to DEBUG_ANY_ID, the symbol is appended to the end of the list.

When this method returns, *Index* points to the actual index of the symbol. The index of a symbol is an identification number. The index ranges from zero through the number of symbols in the symbol group minus one.

Return value

Return code	Description
S_OK	The method was successful.

This method can also return error values. For more information, see [Return Values](#).

Remarks

The symbol name in *Name* is evaluated by the [C++ expression evaluator](#) and can contain any C++ expression (for example, *x+y*).

If the index that you want is less than the size of the symbol group, the new symbol is added at the desired index. If the desired index is larger than the size of the symbol group, the new symbol is added to the end of the list (as in the case of DEBUG_ANY_ID).

For more information about symbol groups, see [Scopes and Symbol Groups](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugSymbolGroup](#)
[IDebugSymbolGroup2](#)

[RemoveSymbolByIndex](#)
[RemoveSymbolByName](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugSymbolGroup::ExpandSymbol method

The **ExpandSymbol** method adds or removes the children of a symbol from a symbol group.

Syntax

```
C++
HRESULT ExpandSymbol(
    [in] ULONG Index,
    [in] BOOL   Expand
);
```

Parameters

Index [in]

The index of the symbol whose children will be added or removed. The index of a symbol is an identification number. The index ranges from zero through the number of symbols in the symbol group minus one.

Expand [in]

A Boolean value that specifies whether to add or remove the symbols children from the symbol group. If *Expand* is true, the children are added. If *Expand* is false, the children are removed.

Return value

	Return code	Description
S_OK		The method was successful.
S_FALSE		The symbol has no children to add.
E_INVALIDARG		The depth of the symbol is DEBUG_SYMBOL_EXPANSION_LEVEL_MASK, which is the maximum depth. This depth prevented the specified symbol's children from being added to this symbol group.

This method can also return other error values. For more information, see [Return Values](#).

Remarks

For more information about symbol groups, see [Scopes and Symbol Groups](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugSymbolGroup](#)
[IDebugSymbolGroup2](#)
[GetNumberSymbols](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugSymbolGroup::GetNumberSymbols method

The `GetNumberSymbols` method returns the number of [symbols](#) that are contained in a symbol group.

Syntax

```
C++  
HRESULT GetNumberSymbols(  
    [out] PULONG Number  
) ;
```

Parameters

Number [out]

The number of symbols that are contained in this symbol group.

Return value

Return code	Description
S_OK	The method was successful.

This method can also return error values. For more information, see [Return Values](#).

Remarks

Each symbol in a symbol group is identified by an *index*. This index is a number between zero and the number that is returned to *Number* minus one. Every time that a symbol is added or removed from the symbol group, the index of all of the symbols in the group might change.

For more information about symbol groups, see [Scopes and Symbol Groups](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugSymbolGroup::GetSymbolName method

The `GetSymbolName` method returns the name of a symbol in a symbol group.

Syntax

```
C++  
HRESULT GetSymbolName(  
    [in]     ULONG   Index,  
    [out, optional] PSTR   Buffer,  
    [in]     ULONG   BufferSize,  
    [out, optional] PULONG NameSize  
) ;
```

Parameters

Index [in]

The index of the symbol whose name you want. The index of a symbol is an identification number. The index ranges from zero through the number of symbols in the symbol group minus one.

Buffer [out, optional]

The symbol name. If *Buffer* is **NULL**, this information is not returned.

BufferSize [in]

The size of the buffer that *Buffer* points to.

NameSize [out, optional]

The size of the symbol name. If *NameSize* is **NULL**, this information is not returned.

Return value

Return code	Description
S_OK	The method was successful.
S_FALSE	The method was successful. However, the name of the symbol did not fit in the buffer referred to by the <i>Buffer</i> parameter, so a truncated name was returned.

This method can also return error values. For more information, see [Return Values](#).

Remarks

For more information about symbol groups, see [Scopes and Symbol Groups](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugSymbolGroup::GetSymbolParameters method

The **GetSymbolParameters** method returns the symbol parameters that describe the specified [symbols](#) in a symbol group.

Syntax

```
C++  
HRESULT GetSymbolParameters(  
    [in]     ULONG   Start,  
    [in]     ULONG   Count,  
    [out]    PDEBUG_SYMBOL_PARAMETERS Params  
) ;
```

Parameters

Start [in]

The index in the symbol group of the first symbol whose parameters you want. The index of a symbol is an identification number. This number ranges from zero through the number of symbols in the symbol group minus one.

Count [in]

The number of symbol parameters that you want.

Params [out]

The symbol parameters. This array must hold at least *Count* elements. For a description of these parameters, see [DEBUG_SYMBOL_PARAMETERS](#).

Return value

Return code	Description
S_OK	The method was successful.

This method can also return error values. For more information, see [Return Values](#).

Remarks

For more information about symbol groups, see [Scopes and Symbol Groups](#).

Requirements

Target platform

IDebugSymbolGroup::RemoveSymbolByIndex method

The **RemoveSymbolByIndex** method removes the specified symbol from a symbol group.

Syntax

C++
HRESULT RemoveSymbolByIndex(
 [in] ULONG Index
) ;

Parameters

Index [in]

The index of the symbol to remove. The index of a symbol is an identification number. The index ranges from zero through the number of symbols in the symbol group minus one.

Return value

RemoveSymbolByIndex might return one of the following values:

Return code	Description
S_OK	The method was successful.

This method can also return error values. For more information, see [Return Values](#).

Remarks

When a symbol is removed, the indexes of the symbols that remain in the symbol group might change.

For more information about symbol groups, see [Scopes and Symbol Groups](#).

IDebugSymbolGroup::RemoveSymbolByName method

The **RemoveSymbolByName** method removes the specified symbol from a symbol group.

Syntax

```
C++  
HRESULT RemoveSymbolByName(  
    [in] PCSTR Name  
) ;
```

Parameters

Name [in]

The name of the symbol to remove from the symbol group.

Return value

RemoveSymbolByName might return one of the following values:

Return code	Description
S_OK	The method was successful.

This method can also return error values. For more information, see [Return Values](#).

Remarks

When a symbol is removed, the indexes of the symbols that remain in the symbol group might change.

For more information about symbol groups, see [Scopes and Symbol Groups](#).

Requirements

Target platform

IDebugSymbolGroup::OutputAsType method

The **OutputAsType** method changes the type of a symbol in a symbol group. The symbol's entry is updated to represent the new type.

Syntax

```
C++  
HRESULT OutputAsType(  
    [in] ULONG Index,  
    [in] PCSTR Type  
) ;
```

Parameters

Index [in]

The index of the entry in this symbol group. The *index* of a symbol is an identification number. The index ranges from zero through the number of symbols in the symbol group minus one.

Type [in]

The name of the type of the symbol that you want. If the name begins with an exclamation mark (!), the name is treated as an extension. For more information about how to use an extension as a type, see the Remarks section.

Return value

Return code	Description
S_OK	The method was successful.

This method can also return error values. For more information, see [Return Values](#).

Remarks

Because the children of the new entry type might differ from the children of the old entry type, the **OutputAsType** method removes all of the children of the entry from the symbol group. You can add the children back by using the [ExpandSymbol](#) method.

If *Type* is an extension, the address of the symbol is passed to the extension. Every line of output from the extension becomes a child symbol of the specified symbol. These child symbols are text and you cannot manipulate them in any way. For example, if the name of a variable is @\$teb, you can change its type to tteb.

For more information about symbol groups, see [Scopes and Symbol Groups](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugSymbolGroup](#)
[IDebugSymbolGroup2](#)

IDebugSymbolGroup::OutputSymbols method

The **OutputSymbols** method prints the specified [symbols](#) to the debugger console.

Syntax

```
C++  
HRESULT OutputSymbols(  
    [in] ULONG OutputControl,  
    [in] ULONG Flags,  
    [in] ULONG Start,  
    [in] ULONG Count
```

) ;

Parameters

OutputControl [in]

The output control to use when printing the symbols' information. For more information about possible values, see [DEBUG_OUTCTL_XXX](#). For more information about output, see [Input and Output](#).

Flags [in]

The flags that determine what information is printed for each symbol. By default, the output includes the symbol's name, offset, value, and type. The format for the output is as follows:

Name**NAME**Offset**OFF**Value**VALUE**Type**TYPE**

You can use the following bit flags to suppress the output of one of these pieces of information together with the corresponding marker.

Value	Description
DEBUG_OUTPUT_SYMBOLS_NO_NAMES	Suppress output of the symbol's name.
DEBUG_OUTPUT_SYMBOLS_NO_OFFSETS	Suppress output of the symbol's offset.
DEBUG_OUTPUT_SYMBOLS_NO_VALUES	Suppress output of the symbol's value.
DEBUG_OUTPUT_SYMBOLS_NO_TYPES	Suppress output of the symbol's type.

Start [in]

The index of the first symbol in the symbol group to print. The index of a symbol is an identification number. This number ranges from zero through the number of symbols in the symbol group minus one.

Count [in]

The number of symbols to print.

Return value

Return code	Description
S_OK	The method was successful.

This method can also return error values. For more information, see [Return Values](#).

Remarks

For more information about symbol groups, see [Scopes and Symbol Groups](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

IDebugSymbolGroup::WriteSymbol method

The **WriteSymbol** methods set the value of the specified symbol.

Syntax

C++

```
HRESULT WriteSymbol(
    [in] ULONG Index,
    [in] PCSTR Value
```

) ;

Parameters

Index [in]

The index of the symbol whose value will be changed. The index of a symbol is an identification number. The index ranges from zero through the number of symbols in the symbol group minus one.

Value [in]

A C++ expression that is evaluated to give the symbol's new value.

Return value

Return code	Description
S_OK	The method was successful.

This method can also return error values. For more information, see [Return Values](#).

Remarks

The **WriteSymbol** method can change symbols only if the symbols are stored in a register or memory location that the [debugger engine](#) knows and if they have not had their type changed to an extension by using the [OutputAsType](#) method.

For more information about symbol groups, see [Scopes and Symbol Groups](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugSymbolGroup2 interface

Members

The **IDebugSymbolGroup2** interface inherits from [IDebugSymbolGroup](#). **IDebugSymbolGroup2** also has these types of members:

- [Methods](#)

Methods

The **IDebugSymbolGroup2** interface has these methods.

Method	Description
AddSymbolWide	Adds a symbol to a symbol group.
GetSymbolEntryInformation	Returns information about a symbol in a symbol group.
GetSymbolNameWide	Returns the name of a symbol in a symbol group.
GetSymbolOffset	Retrieves the location in the process's virtual address space of a symbol in a symbol group, if the symbol has an absolute address.
GetSymbolRegister	Returns the register that contains the value or a pointer to the value of a symbol in a symbol group.
GetSymbolSize	Returns the size of a symbol's value.
GetSymbolTypeName	Returns the name of the specified symbol's type. (ANSI version)
GetSymbolTypeNameWide	Returns the name of the specified symbol's type. (Unicode version)
GetSymbolValueText	Returns a string that represents the value of a symbol. (ANSI version)
GetSymbolValueTextWide	Returns a string that represents the value of a symbol. (Unicode version)
OutputAsTypeWide	Changes the type of a symbol in a symbol group. The symbol's entry is updated to represent the new type.
RemoveSymbolByNameWide	Removes the specified symbol from a symbol group.

[WriteSymbolWide](#)

Sets the value of the specified symbol.

Requirements

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugSymbolGroup](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugSymbolGroup2::AddSymbolWide method

The **AddSymbolWide** method adds a symbol to a [symbol group](#).

Syntax

```
C++  
HRESULT AddSymbolWide(  
    [in]     PCWSTR Name,  
    [in, out] PULONG Index  
) ;
```

Parameters

Name [in]

The symbol's name. *Name* is examined as an expression to determine the symbol's [type](#). This expression can include pointer, array, and structure dereferencing (for example, `*my_pointer`, `my_array[1]`, or `my_struct.some_field`).

Index [in, out]

The index of the entry in the symbol group. When you are calling [AddSymbol](#) or [AddSymbolWide](#), *Index* should point to the index of the symbol that you want. Or, if *Index* points to DEBUG_ANY_ID, the symbol is appended to the end of the list.

When this method returns, *Index* points to the actual index of the symbol. The index of a symbol is an identification number. The index ranges from zero through the number of symbols in the symbol group minus one.

Return value

Return code	Description
S_OK	The method was successful.

This method can also return error values. For more information, see [Return Values](#).

Remarks

The symbol name in *Name* is evaluated by the [C++ expression evaluator](#) and can contain any C++ expression (for example, `x+y`).

If the index that you want is less than the size of the symbol group, the new symbol is added at the desired index. If the desired index is larger than the size of the symbol group, the new symbol is added to the end of the list (as in the case of DEBUG_ANY_ID).

For more information about symbol groups, see [Scopes and Symbol Groups](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

IDebugSymbolGroup2::GetSymbolEntryInformation method

The **GetSymbolEntryInformation** method returns information about a symbol in a symbol group.

Syntax

C++

```
HRESULT GetSymbolEntryInformation(
    [in]    ULONG          Index,
    [out]   PDEBUG_SYMBOL_ENTRY Entry
);
```

Parameters

Index [in]

The index of the symbol whose information you want. The index of a symbol is an identification number. The index ranges from zero through the number of symbols in the symbol group minus one.

Entry [out]

The information about the symbol. For more information about this structure, see [DEBUG SYMBOL ENTRY](#).

Return value

Return code	Description
S_OK	The method was successful.

This method can also return error values. For more information, see [Return Values](#).

Remarks

For more information about symbol groups, see [Scopes and Symbol Groups](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

IDebugSymbolGroup2::GetSymbolNameWide method

The **GetSymbolNameWide** method returns the name of a symbol in a symbol group.

Syntax

C++

```
HRESULT GetSymbolNameWide(
    [in]    ULONG          Index,
    [out, optional] PWSTR Buffer,
    [in]    ULONG          BufferSize,
    [out, optional] PULONG NameSize
);
```

Parameters

Index [in]

The index of the symbol whose name you want. The index of a symbol is an identification number. The index ranges from zero through the number of symbols in the symbol group minus one.

Buffer [out, optional]

The symbol name. If *Buffer* is **NULL**, this information is not returned.

BufferSize [in]

The size of the buffer that *Buffer* points to.

NameSize [out, optional]

The size of the symbol name. If *NameSize* is **NULL**, this information is not returned.

Return value

Return code	Description
S_OK	The method was successful.
S_FALSE	The method was successful. However, the name of the symbol did not fit in the buffer referred to by the <i>Buffer</i> parameter, so a truncated name was returned.

This method can also return error values. For more information, see [Return Values](#).

Remarks

For more information about symbol groups, see [Scopes and Symbol Groups](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

[GetNumberSymbols](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugSymbolGroup2::GetSymbolOffset method

The **GetSymbolOffset** method retrieves the location in the process's virtual address space of a symbol in a symbol group, if the symbol has an absolute address.

Syntax

```
C++  
HRESULT GetSymbolOffset(  
    [in]  ULONG   Index,  
    [out] PULONG64 Offset  
) ;
```

Parameters

Index [in]

The index of the symbol whose address you want. The index of a symbol is an identification number. The index ranges from zero through the number of symbols in the symbol group minus one.

Offset [out]

The location in the process's virtual address space of the symbol.

Return value

Return code	Description
S_OK	The method was successful.
E_NOINTERFACE	The symbol does not have an absolute address.

This method can also return error values. For more information, see [Return Values](#).

Remarks

For more information about symbol groups, see [Scopes and Symbol Groups](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugSymbolGroup2](#)
[GetNumberSymbols](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

IDebugSymbolGroup2::GetSymbolRegister method

The **GetSymbolRegister** method returns the register that contains the value or a pointer to the value of a symbol in a symbol group.

Syntax

```
C++
HRESULT GetSymbolRegister(
    [in]    ULONG   Index,
    [out]   PULONG  Register
);
```

Parameters

Index [in]

The index of the symbol to return the register for. The index of a symbol is an identification number. The index ranges from zero through the number of symbols in the symbol group minus one.

Register [out]

The index of the register that contains the value or a pointer to the value of the symbol.

Return value

Return code	Description
S_OK	The method was successful.
E_NOINTERFACE	The symbol's value and a pointer to it are not contained in a register, or the register is not known.

This method can also return error values. For more information, see [Return Values](#).

Remarks

For more information about symbol groups, see [Scopes and Symbol Groups](#). For more information about registers and the register index, see [Registers](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugSymbolGroup2::GetSymbolSize method

The **GetSymbolSize** method returns the size of a symbol's value.

Syntax

```
C++  
HRESULT GetSymbolSize(  
    [in]    ULONG   Index,  
    [out]   PULONG  Size  
) ;
```

Parameters

Index [in]

The index of the symbol to remove. The index of a symbol is an identification number. The index ranges from zero through the number of symbols in the symbol group minus one.

Size [out]

The size, in bytes, of the symbol's value. This information might not be available. If this information is not available, *Size* is set to zero. For some symbols (for example, a function's code), the data might be split over multiple regions. In this situation, *Size* is not meaningful.

Return value

Return code	Description
S_OK	The method was successful.
E_NOINTERFACE	The symbol does not have type data associated with it.

This method can also return other error values. For more information, see [Return Values](#).

Remarks

For more information about symbol groups, see [Scopes and Symbol Groups](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugSymbolGroup2::GetSymbolTypeName method

The **GetSymbolTypeName** methods return the name of the specified symbol's type.

Syntax

```
C++  
HRESULT GetSymbolTypeName(  
    [in]    ULONG   Index,  
    [out, optional] PSTR   Buffer,
```

```
[in]           ULONG BufferSize,
[out, optional] PULONG NameSize
);
```

Parameters

Index [in]

The index of the symbol whose type name you want. The index of a symbol is an identification number. The index ranges from zero through the number of symbols in the symbol group minus one.

Buffer [out, optional]

The name of the symbol's type. If *Buffer* is **NULL**, this information is not returned.

BufferSize [in]

The size, in characters, of the *Buffer* buffer.

NameSize [out, optional]

The size, in characters, of the name of the symbol's type. If *NameSize* is **NULL**, this information is not returned.

Return value

Return code	Description
S_OK	The method was successful.
S_FALSE	The size of the buffer was smaller than the size of the name of the symbol's type. The buffer is filled with the truncated name.

This method can also return error values. For more information, see [Return Values](#).

Remarks

For more information about symbol groups, see [Scopes and Symbol Groups](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

IDebugSymbolGroup2::GetSymbolTypeNameWide method

The **GetSymbolTypeNameWide** method returns the name of the specified symbol's type.

Syntax

```
C++
HRESULT GetSymbolTypeNameWide(
[in]           ULONG Index,
[out, optional] PWSTR Buffer,
[in]           ULONG BufferSize,
[out, optional] PULONG NameSize
);
```

Parameters

Index [in]

The index of the symbol whose type name you want. The index of a symbol is an identification number. The index ranges from zero through the number of symbols in the symbol group minus one.

Buffer [out, optional]

The name of the symbol's type. If *Buffer* is **NULL**, this information is not returned.

BufferSize [in]

The size, in characters, of the *Buffer* buffer.

NameSize [out, optional]

The size, in characters, of the name of the symbol's type. If *NameSize* is **NULL**, this information is not returned.

Return value

Return code	Description
S_OK	The method was successful.
S_FALSE	The size of the buffer was smaller than the size of the name of the symbol's type. The buffer is filled with the truncated name.

This method can also return error values. For more information, see [Return Values](#).

Remarks

For more information about symbol groups, see [Scopes and Symbol Groups](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

[IDebugSymbolGroup2](#)
[GetNumberSymbols](#)
[IDebugSymbols::GetTypeName](#)

IDebugSymbolGroup2::GetSymbolValueText method

The **GetSymbolValueText** method returns a string that represents the value of a symbol.

Syntax

C++

```
HRESULT GetSymbolValueText(
    [in]           ULONG   Index,
    [out, optional] PSTR    Buffer,
    [in]           ULONG   BufferSize,
    [out, optional] PULONG  NameSize
);
```

Parameters

Index [in]

The index of the symbol whose value you want. The index of a symbol is an identification number. The index ranges from zero through the number of symbols in the symbol group minus one.

Buffer [out, optional]

The value of the symbol as a string. If *Buffer* is **NULL**, this information is not returned.

BufferSize [in]

The size, in characters, of the *Buffer* buffer.

NameSize [out, optional]

The size, in characters, of the value of the symbol. If *NameSize* is **NULL**, this information is not returned.

Return value

Return code	Description
S_OK	The method was successful.
S_FALSE	The method was successful. However, the value of the symbol would not fit in the buffer referred to by the <i>Buffer</i> parameter, so a truncated value was returned.

This method can also return error values. For more information, see [Return Values](#).

Remarks

If you added the symbol to the symbol group by using the [AddSymbol](#) method, the string that is returned to *Buffer* is the name of the symbol that is passed to [AddSymbol](#).

For more information about symbol groups, see [Scopes and Symbol Groups](#).

Requirements

Target platform

Header Dbgeng.h (include Dbgeng.h)

See also

IDebugSymbolGroup2::GetSymbolValueTextWide method

The [GetSymbolValueTextWide](#) method returns a string that represents the value of a symbol.

Syntax

```
C++
HRESULT GetSymbolValueTextWide(
    [in]           ULONG   Index,
    [out, optional] PWSTR   Buffer,
    [in]           ULONG   BufferSize,
    [out, optional] PULONG  NameSize
);
```

Parameters

Index [in]

The index of the symbol whose value you want. The index of a symbol is an identification number. The index ranges from zero through the number of symbols in the symbol group minus one.

Buffer [out, optional]

The value of the symbol as a string. If *Buffer* is **NULL**, this information is not returned.

BufferSize [in]

The size, in characters, of the *Buffer* buffer.

NameSize [out, optional]

The size, in characters, of the value of the symbol. If *NameSize* is **NULL**, this information is not returned.

Return value

Return code	Description
S_OK	The method was successful.
S_FALSE	The method was successful. However, the value of the symbol would not fit in the buffer referred to by the <i>Buffer</i> parameter, so a truncated value was returned.

This method can also return error values. For more information, see [Return Values](#).

Remarks

If you added the symbol to the symbol group by using the [AddSymbol](#) method, the string that is returned to *Buffer* is the name of the symbol that is passed to [AddSymbol](#).

For more information about symbol groups, see [Scopes and Symbol Groups](#).

IDebugSymbolGroup2::OutputAsTypeWide method

The **OutputAsTypeWide** method changes the type of a symbol in a symbol group. The symbol's entry is updated to represent the new type.

Syntax

```
C++
HRESULT OutputAsTypeWide(
    [in] ULONG Index,
    [in] PCWSTR Type
);
```

Parameters

Index [in]

The index of the entry in this symbol group. The *index* of a symbol is an identification number. The index ranges from zero through the number of symbols in the symbol group minus one.

Type [in]

The name of the type of the symbol that you want. If the name begins with an exclamation mark (!), the name is treated as an extension. For more information about how to use an extension as a type, see the Remarks section.

Return value

Return code	Description
S_OK	The method was successful.

This method can also return error values. For more information, see [Return Values](#).

Remarks

Because the children of the new entry type might differ from the children of the old entry type, the **OutputAsTypeWide** method removes all of the children of the entry from the symbol group. You can add the children back by using the [ExpandSymbol](#) method.

If *Type* is an extension, the address of the symbol is passed to the extension. Every line of output from the extension becomes a child symbol of the specified symbol. These child symbols are text and you cannot manipulate them in any way. For example, if the name of a variable is `@$teb`, you can change its type to `!teb`.

For more information about symbol groups, see [Scopes and Symbol Groups](#).

IDebugSymbolGroup2::RemoveSymbolByNameWide method

The **RemoveSymbolByNameWide** method removes the specified symbol from a symbol group.

Syntax

```
C++  
HRESULT RemoveSymbolByNameWide(  
    [in] PCWSTR Name  
) ;
```

Parameters

Name [in]

The name of the symbol to remove from the symbol group.

Return value

RemoveSymbolByNameWide might return one of the following values:

Return code	Description
S_OK	The method was successful.

This method can also return error values. For more information, see [Return Values](#).

Remarks

When a symbol is removed, the indexes of the symbols that remain in the symbol group might change.

For more information about symbol groups, see [Scopes and Symbol Groups](#).

Requirements

Target platform

IDebugSymbolGroup2::WriteSymbolWide method

The **WriteSymbolWide** method sets the value of the specified symbol.

Syntax

```
C++  
HRESULT WriteSymbolWide(  
    [in] ULONG Index,  
    [in] PCWSTR Value  
) ;
```

Parameters

Index [in]

The index of the symbol whose value will be changed. The index of a symbol is an identification number. The index ranges from zero through the number of symbols in the symbol group minus one.

Value [in]

A C++ expression that is evaluated to give the symbol's new value.

Return value

Return code	Description
S_OK	The method was successful.

This method can also return error values. For more information, see [Return Values](#).

Remarks

This method can change symbols only if the symbols are stored in a register or memory location that the [debugger engine](#) knows and if they have not had their type changed to an extension by using the [OutputAsType](#) method.

For more information about symbol groups, see [Scopes and Symbol Groups](#).

DEBUG_ASMOPT_XXX

The assembly and disassembly options affect how the debugger engine assembles and disassembles processor instructions for the target.

The options are represented by a bitset with the following bit flags.

Constant	Description
DEBUG_ASMOPT_VERBOSE	When this bit is set, additional information is included in the disassembly. This is equivalent to the verbose option in the .asm command.
DEBUG_ASMOPT_NO_CODE_BYTES	When this bit is set, the raw bytes for an instruction are not included in the disassembly. This is equivalent to the no_code_bytes option in the .asm command.
DEBUG_ASMOPT_IGNORE_OUTPUT_WIDTH	When this bit is set, the debugger ignores the width of the output display when formatting instructions during disassembly. This is equivalent to the ignore_output_width option in the .asm command.
DEBUG_ASMOPT_SOURCE_LINE_NUMBER	When this bit is set, each line of the disassembly output is prefixed with the line number of the source code provided by symbol information. This is equivalent to the source_line option in the .asm command.

Remarks

Additionally, the value DEBUG_ASMOPT_DEFAULT represents the default set of assembly and disassembly options. This means that all the options in the preceding table

are turned off.

DEBUG_ATTACH_XXX

The DEBUG_ATTACH_XXX bit-flags described in this topic control how the [debugger engine](#) attaches to a user-mode process. For the DEBUG_ATTACH_XXX options used when attaching to a kernel target, see [AttachKernel](#).

The following table describes the possible flag values.

Constant	Description
DEBUG_ATTACH_NONINVASIVE	Attach to the target noninvasively. For more information about noninvasive debugging, see Noninvasive Debugging (User Mode) .
DEBUG_ATTACH_EXISTING	If this flag is set, then the flags DEBUG_ATTACH_EXISTING, DEBUG_ATTACH_INVASIVE_NO_INITIAL_BREAK, and DEBUG_ATTACH_INVASIVE_RESUME_PROCESS must not be set. Re-attach to an application to which a debugger has already attached (and possibly abandoned). For more information about re-attaching to targets, see Re-attaching to the Target Application .
DEBUG_ATTACH_NONINVASIVE_NO_SUSPEND	If this flag is set, then the other DEBUG_ATTACH_XXX flags must not be set. Do not suspend the target's threads when attaching noninvasively.
DEBUG_ATTACH_INVASIVE_NO_INITIAL_BREAK	If this flag is set, then the flag DEBUG_ATTACH_NONINVASIVE must also be set. (Windows XP and later) Do not request an initial break-in when attaching to the target.
DEBUG_ATTACH_INVASIVE_RESUME_PROCESS	If this flag is set, then the flags DEBUG_ATTACH_NONINVASIVE and DEBUG_ATTACH_EXISTING must not be set. Resume all of the target's threads when attaching invasively.
	If this flag is set, then the flags DEBUG_ATTACH_NONINVASIVE and DEBUG_ATTACH_EXISTING must not be set.

Requirements

Header DbgEng.h (include DbgEng.h)

DEBUG_BREAKPOINT_PARAMETERS structure

The DEBUG_BREAKPOINT_PARAMETERS structure contains most of the parameters for describing a breakpoint.

Syntax

C++

```
typedef struct _DEBUG_BREAKPOINT_PARAMETERS {
    ULONG64 Offset;
    ULONG     Id;
    ULONG     BreakType;
    ULONG     ProcType;
```

```
ULONG Flags;
ULONG DataSize;
ULONG DataAccessType;
ULONG PassCount;
ULONG CurrentPassCount;
ULONG MatchThread;
ULONG CommandSize;
ULONG OffsetExpressionSize;
} DEBUG_BREAKPOINT_PARAMETERS, *PDEBUG_BREAKPOINT_PARAMETERS;
```

Members

Offset

The location in the target's memory address space that will trigger the breakpoint. If the breakpoint is deferred (see [GetFlags](#)), **Offset** is DEBUG_INVALID_OFFSET. See [GetOffset](#).

Id

The breakpoint ID. See [GetId](#).

BreakType

Specifies if the breakpoint is a software breakpoint or a processor breakpoint. See [GetType](#).

ProcType

The processor type for which the breakpoint is set. See [GetType](#).

Flags

The flags for the breakpoint. See [GetFlags](#).

DataSize

The size, in bytes, of the memory block whose access will trigger the breakpoint. If the type of the breakpoint is not a data breakpoint, this is zero. See [GetDataParameters](#).

DataAccessType

The type of access that will trigger the breakpoint. If the type of the breakpoint is not a data breakpoint, this is zero. See [GetDataParameters](#).

PassCount

The number of times the target will hit the breakpoint before it is triggered. See [GetPassCount](#).

CurrentPassCount

The remaining number of times that the target will hit the breakpoint before it is triggered. See [GetCurrentPassCount](#).

MatchThread

The engine thread ID of the thread that can trigger this breakpoint. If any thread can trigger this breakpoint, **MatchThread** is DEBUG_ANY_ID. See [GetMatchThreadId](#).

CommandSize

The size, in characters, of the command string that will be executed when the breakpoint is triggered. If no command is set, **CommandSize** is zero. See [GetCommand](#).

OffsetExpressionSize

The size, in characters, of the expression string that evaluates to the location in the target's memory address space where the breakpoint is triggered. If no expression string is set, **OffsetExpressionSize** is zero. See [GetOffsetExpression](#).

Remarks

For an overview of how to use breakpoints, and a description of all breakpoint-related methods, see [Breakpoints](#).

Requirements

Header DbgEng.h (include DbgEng.h)

[Send comments about this topic to Microsoft](#)

DEBUG_CREATE_PROCESS_OPTIONS structure

The DEBUG_CREATE_PROCESS_OPTIONS structure specifies the process creation options to use when creating a new process.

Syntax

```
C++
typedef struct _DEBUG_CREATE_PROCESS_OPTIONS {
    ULONG CreateFlags;
    ULONG EngCreateFlags;
    ULONG VerifierFlags;
    ULONG Reserved;
} DEBUG_CREATE_PROCESS_OPTIONS, *PDEBUG_CREATE_PROCESS_OPTIONS;
```

Members

CreateFlags

The flags to use when creating the process. In addition to the flags described in the "Process Creation Flags" topic in the Platform SDK documentation, the [debugger engine](#) uses the following flags when creating a process.

Values	Description
DEBUG_CREATE_PROCESS_NO_DEBUG_HEAP (Microsoft Windows Server 2003 and later)	Prevents the debug heap from being used in the new process.
DEBUG_CREATE_PROCESS_THROUGH_RTL	The native NT RTL process creation routines should be used instead of Win32. This is only meaningful for special processes that run as NT native processes. No Win32 process can be created with this flag.

When creating and attaching to a process through the debugger engine, set one of the Platform SDK's process creation flags: DEBUG_PROCESS or DEBUG_ONLY_THIS_PROCESS.

EngCreateFlags

The engine specific flags used when creating the process. **EngCreateFlags** is a combination of the following bit-flags:

Value	Description
DEBUG_ECREATE_PROCESS_INHERIT_HANDLES	The new process will inherit system handles from the debugger or process server.
DEBUG_ECREATE_PROCESS_USE_VERIFIER_FLAGS	(Windows Vista and later) Use Application Verifier flags in the VerifierFlags field.
DEBUG_ECREATE_PROCESS_USE_IMPLICIT_COMMAND_LINE	Use the debugger's or process server's implicit command line to start the process instead of a supplied command line.

VerifierFlags

The Application Verifier flags. Only used if DEBUG_ECREATE_PROCESS_USE_VERIFIER_FLAGS is set in the **EngCreateFlags** field. For possible values, see the [Application Verifier](#) documentation.

Reserved

Set to zero.

Requirements

Header DbgEng.h (include DbgEng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

DEBUG_DUMP_XXX

The DEBUG_DUMP_XXX constants are used by the methods [WriteDumpFile](#), [WriteDumpFile2](#), and [WriteDumpFileWide](#) to specify the type of crash dump file to create.

The possible values include the following.

Constant	Description
DEBUG_DUMP_SMALL	Creates a Small Memory Dump (kernel-mode) or Minidump (user-mode).
DEBUG_DUMP_DEFAULT	Creates a Full User-Mode Dump (user-mode) or Kernel Summary Dump (kernel-mode).
DEBUG_DUMP_FULL	Creates a Complete Memory Dump (kernel-mode only)

Moreover, the following aliases are available for kernel-mode debugging.

Alias	Value
DEBUG_KERNEL_SMALL_DUMP	DEBUG_DUMP_SMALL
DEBUG_KERNEL_DUMP	DEBUG_DUMP_DEFAULT

DEBUG_KERNEL_FULL_DUMP DEBUG_DUMP_FULL

Additionally, the following aliases are available for user-mode debugging.

Alias	Value
DEBUG_USER_WINDOWS_SMALL_DUMP	DEBUG_DUMP_SMALL
DEBUG_USER_WINDOWS_DUMP	DEBUG_DUMP_DEFAULT

Remarks

For a description of kernel-mode dump files, see [Varieties of Kernel-Mode Dump Files](#). For a description of user-mode dump files, see [Varieties of User-Mode Dump Files](#).

Requirements

Header DbgEng.h (include DbgEng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

DEBUG_ENGOPT_XXX

The following global options affect the behavior of the [debugger engine](#).

Constant	Description
DEBUG_ENGOPT_IGNORE_DBGHELP_VERSION	The debugger engine generates a warning instead of an error if the version of the DbgHelp DLL does not match the version of the debugger engine.
DEBUG_ENGOPT_IGNORE_EXTENSION_VERSIONS	Disable version checking for extensions. This suppresses the debugger engine's call to CheckVersion .
DEBUG_ENGOPT_ALLOW_NETWORK_PATHS	Network shares can be used for loading symbols and extensions. This option prevents the engine from disallowing network paths when debugging some system processes and should be used with caution.
DEBUG_ENGOPT_DISALLOW_NETWORK_PATHS	This option cannot be set if DEBUG_ENGOPT_ALLOW_NETWORK_PATHS is set. Network shares cannot be used for loading symbols and extensions. The engine attempts to set this option when debugging some system processes.
DEBUG_ENGOPT_NETWORK_PATHS	This option cannot be set if DEBUG_ENGOPT_ALLOW_NETWORK_PATHS is set. Bitwise OR of DEBUG_ENGOPT_ALLOW_NETWORK_PATHS and DEBUG_ENGOPT_DISALLOW_NETWORK_PATHS.
DEBUG_ENGOPT_IGNORE_LOADER_EXCEPTIONS	Ignore expected first-chance exceptions that are generated by the loader in certain versions of Windows.
DEBUG_ENGOPT_INITIAL_BREAK	For example, this option allows Windows 3.51 binaries to run when debugging Windows 3.1 and 3.5 systems.
DEBUG_ENGOPT_INITIAL_MODULE_BREAK	Break into the debugger at the target's initial event.
DEBUG_ENGOPT_FINAL_BREAK	Break into the debugger when the target loads its first module.
DEBUG_ENGOPT_NO_EXECUTE_REPEAT	Break into the debugger at the target's final event. In a live user-mode target, this is when the process exits. It has no effect in kernel mode.
DEBUG_ENGOPT_FAIL_INCOMPLETE_INFORMATION	When given an empty command, the debugger engine does not repeat the last command.
DEBUG_ENGOPT_ALLOW_READ_ONLY_BREAKPOINTS	Prevent the debugger from loading modules whose images cannot be mapped.
DEBUG_ENGOPT_SYNCHRONIZE_BREAKPOINTS	The debugger attempts to load images when debugging minidumps that do not contain images. Allow the debugger engine to manipulate page protections on the target to allow for setting software breakpoints in a read-only section of memory.
DEBUG_ENGOPT_DISALLOW_SHELL_COMMANDS	When setting software breakpoints, the engine transparently alters the target's memory to insert an interrupt instruction. In live user-mode debugging, the engine performs extra work when inserting and removing breakpoints to ensure that all threads in the target have a consistent breakpoint state at all times.
DEBUG_ENGOPT_KD QUIET MODE	This option is useful when multiple threads can use the code for which the breakpoint is set. However, it can introduce the possibility of deadlocks.
DEBUG_ENGOPT_DISABLE_MANAGED_SUPPORT	Disallow executing shell commands through the debugger.
DEBUG_ENGOPT_DISABLE_MODULE_SYMBOL_LOAD	After this option has been set, it cannot be unset. Turn on quiet mode. For more information, see sq (Set Quiet Mode) . Disables debugger engine support for managed code. If support for managed code is already in use, this option has no effect. The debugger does not load symbols for modules that are loaded while this flag is set.

DEBUG_ENGOPT_DISABLE_EXECUTION_COMMANDS	Prevents any commands that would cause the target to begin executing.
DEBUG_ENGOPT_DISALLOW_IMAGE_FILE_MAPPING	Disallows mapping of image files from disk. For example, this option disallows image mapping for memory content during debugging of minidump files. This option does not affect existing mappings; it affects only subsequent attempts to map image files.
DEBUG_ENGOPT_PREFER_DML	The debugger runs DML-enhanced versions of commands and operations by default.
DEBUG_ENGOPT_DISABLESQM	Disables upload of Software Quality Metrics (SQM) data.

Requirements

Header DbgEng.h (include DbgEng.h)

DEBUG_EVENT_XXX

The following [events](#) are generated by the target.

Flag	IDebugEventCallbacksMethod	Event Description
DEBUG_EVENT_BREAKPOINT	Breakpoint	A breakpoint exception occurred in the target.
DEBUG_EVENT_EXCEPTION	Exception	An exception debugging event occurred in the target.
DEBUG_EVENT_CREATE_THREAD	CreateThread	A create-thread debugging event occurred in the target.
DEBUG_EVENT_EXIT_THREAD	ExitThread	An exit-thread debugging event occurred in the target.
DEBUG_EVENT_CREATE_PROCESS	CreateProcess	A create-process debugging event occurred in the target.
DEBUG_EVENT_EXIT_PROCESS	ExitProcess	An exit-process debugging event occurred in the target.
DEBUG_EVENT_LOAD_MODULE	LoadModule	A module-load debugging event occurred in the target.
DEBUG_EVENT_UNLOAD_MODULE	UnloadModule	A module-unload debugging event occurred in the target.
DEBUG_EVENT_SYSTEM_ERROR	SystemError	A system error occurred in the target.

The following events are generated by the debugger engine.

Flag	IDebugEventCallbacksMethod	Description
DEBUG_EVENT_SESSION_STATUS	SessionStatus	A change has occurred in the session status.
DEBUG_EVENT_CHANGE_DEBUGGEE_STATE	ChangeDebuggeeState	The engine has made or detected a change in the target status.
DEBUG_EVENT_CHANGE_ENGINE_STATE	ChangeEngineState	The engine state has changed.
DEBUG_EVENT_CHANGE_SYMBOL_STATE	ChangeSymbolState	The symbol state has changed.

Requirements

Header DbgEng.h (include DbgEng.h)

DEBUG_EXCEPTION_FILTER_PARAMETERS structure

The DEBUG_EXCEPTION_FILTER_PARAMETERS structure contains the parameters for an exception filter.

Syntax

```
C++
typedef struct _DEBUG_EXCEPTION_FILTER_PARAMETERS {
    ULONG ExecutionOption;
    ULONG ContinueOption;
```

```
ULONG TextSize;
ULONG CommandSize;
ULONG SecondCommandSize;
ULONG ExceptionCode;
} DEBUG_EXCEPTION_FILTER_PARAMETERS, *PDEBUG_EXCEPTION_FILTER_PARAMETERS;
```

Members

ExecutionOption

The [break status](#) of the exception filter, including the terminator. For possible values, see **DEBUG_FILTER_XXX**.

ContinueOption

The [handling status](#) of the exception filter. For possible values, see **DEBUG_FILTER_XXX**.

TextSize

The size, in characters, of the name (including the terminator) of the exception filter. If the filter is an arbitrary exception filter, it does not have a name and **TextSize** is zero.

CommandSize

The size, in characters, of the command (including the terminator) to execute upon the first chance of the exception.

SecondCommandSize

The size, in characters, of the command (including the terminator) to execute upon the second chance of the exception.

ExceptionCode

The exception code for the exception filter.

Requirements

Header DbgEng.h (include DbgEng.h)

See also

[GetExceptionFilterParameters](#)
[SetExceptionFilterParameters](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

DEBUG_FILTER_XXX

The **DEBUG_FILTER_XXX** constants are used for three different purposes: to specify individual specific event filters, to specify the break status of an event filter, and to specify the handling status of an exception filter.

Specific Event Filter

The following constants are used to specify specific event filters.

Value	Event
DEBUG_FILTER_CREATE_THREAD	Create Thread
DEBUG_FILTER_EXIT_THREAD	Exit Thread
DEBUG_FILTER_CREATE_PROCESS	Create Process
DEBUG_FILTER_EXIT_PROCESS	Exit Process
DEBUG_FILTER_LOAD_MODULE	Load Module
DEBUG_FILTER_UNLOAD_MODULE	Unload Module
DEBUG_FILTER_SYSTEM_ERROR	System Error
DEBUG_FILTER_INITIAL_BREAKPOINT	Initial Break Point
DEBUG_FILTER_INITIAL_MODULE_LOAD	Initial Module Load
DEBUG_FILTER_DEBUGGEE_OUTPUT	Target Output

Break Status

The following constants are used to specify the break status of an event filter.

Value	Description
-------	-------------

<code>DEBUG_FILTER_BREAK</code>	The event will break into the debugger.
<code>DEBUG_FILTER_SECOND_CHANCE_BREAK</code>	The event will break into the debugger if it is a second chance exception.
<code>DEBUG_FILTER_OUTPUT</code>	A notification of the event will be printed to the debugger console.
<code>DEBUG_FILTER_IGNORE</code>	The event is ignored.

Additionally, for an arbitrary exception filter, setting the break status to `DEBUG_FILTER_REMOVE`, removes the event filter.

Handling Status

The following constants are used to specify the handling status of an exception filter.

Value	Description
<code>DEBUG_FILTER_GO_HANDLED</code>	The <i>exception</i> has been handled.
<code>DEBUG_FILTER_GO_NOT_HANDLED</code>	The exception has not been handled.

Requirements

Header DbgEng.h (include DbgEng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

DEBUG_FIND_SOURCE_XXX

The `DEBUG_FIND_SOURCE_XXX` bit-flags are used to control the behavior of the methods [FindSourceFile](#) and [FindSourceFileAndToken](#) when searching for source files.

The flags can be any combination of values from the following table.

Constant	Description
<code>DEBUG_FIND_SOURCE_FULL_PATH</code>	Always return the full canonical path name for the found file.
<code>DEBUG_FIND_SOURCE_BEST_MATCH</code>	If not set and the source path contains relative directories, relative path names can be returned.
<code>DEBUG_FIND_SOURCE_NO_SRCSRV</code>	Continue searching after a match has been found to look for a better match.
<code>DEBUG_FIND_SOURCE_TOKEN_LOOKUP</code>	Do not include source servers in the search.
	Return a variable associated with a file token.
	If this flag is set, the other flags are ignored. This flag cannot be used in the FindSourceFile method.

Remarks

The value `DEBUG_FIND_SOURCE_DEFAULT` defines the default set of flags, which means that all of the flags in the previous table are turned off.

Requirements

Header DbgEng.h (include DbgEng.h)

[FindSourceFile](#)
[FindSourceFileAndToken](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

DEBUG_FORMAT_XXX

The `DEBUG_FORMAT_XXX` bit-flags are used by [WriteDumpFile2](#) and [WriteDumpFileWide](#) to determine the format of a crash dump file and, for user-mode Minidumps, what information to include in the file.

The following bit-flags apply to all crash dump files.

Value	Description
DEBUG_FORMAT_WRITE_CAB	Package the crash dump file in a CAB file. The supplied file name or file handle is used for the CAB file; the crash dump is first created in a temporary file before being moved into the CAB file.
DEBUG_FORMAT_CAB_SECONDARY_FILES	Include the current symbols and mapped images in the CAB file. If DEBUG_FORMAT_WRITE_CAB is not set, this flag is ignored.
DEBUG_FORMAT_NO_OVERWRITE	Do not overwrite existing files.

The following bit-flags can also be included for user-mode Minidumps.

Value	Description
DEBUG_FORMAT_USER_SMALL_FULL_MEMORY	Add full memory data. All accessible committed pages owned by the target application will be included.
DEBUG_FORMAT_USER_SMALL_HANDLE_DATA	Add data about the handles that are associated with the target application.
DEBUG_FORMAT_USER_SMALL_UNLOADED_MODULES	Add unloaded module information. This information is available only in Windows Server 2003 and later versions of Windows.
DEBUG_FORMAT_USER_SMALL_INDIRECT_MEMORY	Add indirect memory. A small region of memory that surrounds any address that is referenced by a pointer on the stack or backing store is included.
DEBUG_FORMAT_USER_SMALL_DATA_SEGMENTS	Add all data segments within the executable images.
DEBUG_FORMAT_USER_SMALL_FILTER_MEMORY	Set to zero all of the memory on the stack and in the backing store that is not useful for recreating the stack trace. This can make compression of the Minidump more efficient and increase privacy by removing unnecessary information.
DEBUG_FORMAT_USER_SMALL_FILTER_PATHS	Remove the module paths, leaving only the module names. This is useful for protecting privacy by hiding the directory structure (which may contain the user's name).
DEBUG_FORMAT_USER_SMALL_PROCESS_THREAD_DATA	Add the process environment block (PEB) and thread environment block (TEB). This flag can be used to provide Windows system information for threads and processes.
DEBUG_FORMAT_USER_SMALL_PRIVATE_READ_WRITE_MEMORY	Add all committed private read-write memory pages.
DEBUG_FORMAT_USER_SMALL_NO_OPTIONAL_DATA	Prevent privacy-sensitive data from being included in the Minidump. Currently, this flag excludes from the Minidump data that would have been added due to the following flags being set: DEBUG_FORMAT_USER_SMALL_PROCESS_THREAD_DATA, DEBUG_FORMAT_USER_SMALL_FULL_MEMORY, DEBUG_FORMAT_USER_SMALL_INDIRECT_MEMORY, DEBUG_FORMAT_USER_SMALL_PRIVATE_READ_WRITE_MEMORY.
DEBUG_FORMAT_USER_SMALL_FULL_MEMORY_INFO	Add all basic memory information. This is the information returned by the QueryVirtual method. The information for all memory is included, not just valid memory, which allows the debugger to reconstruct the complete virtual memory layout from the Minidump.
DEBUG_FORMAT_USER_SMALL_THREAD_INFO	Add additional thread information, which includes execution time, start time, exit time, start address, and exit status.
DEBUG_FORMAT_USER_SMALL_CODE_SEGMENTS	Add all code segments with the executable images.

Requirements

Header DbgEng.h (include DbgEng.h)

DEBUG_HANDLE_DATA_BASIC structure

The DEBUG_HANDLE_DATA_BASIC structure contains handle-related information about a system object.

Syntax

```

C++
typedef struct _DEBUG_HANDLE_DATA_BASIC {
    ULONG TypeNameSize;
    ULONG ObjectNameSize;
    ULONG Attributes;
    ULONG GrantedAccess;
    ULONG HandleCount;
    ULONG PointerCount;
} DEBUG_HANDLE_DATA_BASIC, *PDEBUG_HANDLE_DATA_BASIC;
```

Members

TypeNameSize

The size, in characters, of the object-type name.

ObjectNameSize

The size, in characters, of the object's name.

Attributes

A bit-set that contains the handle's attributes. For possible values, see "Handle" in the Windows Driver Kit (WDK).

GrantedAccess

A bit-set that specifies the access mask for the object that is represented by the handle. For details, see ACCESS_MASK in the Platform SDK documentation.

HandleCount

The number of handle references for the object.

PointerCount

The number of pointer references for the object.

Requirements

Header DbgEng.h (include DbgEng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

DEBUG_MODULE_AND_ID structure

The DEBUG_MODULE_AND_ID structure describes a symbol within a module.

Syntax

C++

```
typedef struct _DEBUG_MODULE_AND_ID {
    ULONG64 ModuleBase;
    ULONG64 Id;
} DEBUG_MODULE_AND_ID, *PDEBUG_MODULE_AND_ID;
```

Members

ModuleBase

The location in the target's virtual address space of the module's base address.

Id

The symbol ID of the symbol within the module.

Requirements

Header DbgEng.h (include DbgEng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

DEBUG_MODULE_PARAMETERS structure

The DEBUG_MODULE_PARAMETERS structure contains most of the parameters for describing a module.

Syntax

C++

```
typedef struct _DEBUG_MODULE_PARAMETERS {
    ULONG64 Base;
    ULONG   Size;
    ULONG   TimeDateStamp;
    ULONG   Checksum;
    ULONG   Flags;
}
```

```

ULONG  SymbolType;
ULONG  ImageNameSize;
ULONG  ModuleNameSize;
ULONG  LoadedImageNameSize;
ULONG  SymbolFileNameSize;
ULONG  MappedImageNameSize;
ULONGLONG Reserved[2];
} DEBUG_MODULE_PARAMETERS, *PDEBUG_MODULE_PARAMETERS;

```

Members

Base

The location in the target's virtual address space of the module's base. If the value of **Base** is DEBUG_INVALID_OFFSET, the structure is invalid.

Size

The size, in bytes, of the memory range that is occupied by the module.

TimeDateStamp

The date and time stamp of the module's executable file. This is the number of seconds elapsed since midnight (00:00:00), January 1, 1970 Coordinated Universal Time (UTC) as stored in the image file header.

Checksum

The checksum of the image. This value can be zero.

Flags

A bit-set that contains the module's flags. The bit-flags that can be present are as follows.

Value	Description
DEBUG_MODULE_UNLOADED	The module was unloaded.
DEBUG_MODULE_USER_MODE	The module is a user-mode module.
DEBUG_MODULE_SYM_BAD_CHECKSUM	The checksum in the symbol file did not match the checksum for the module image.

SymbolType

The type of symbols that are loaded for the module. This member can have one of the following values.

Value	Description
DEBUG_SYMBOL_TYPE_NONE	No symbols are loaded.
DEBUG_SYMBOL_TYPE_COFF	The symbols are in common object file format (COFF).
DEBUG_SYMBOL_TYPE_CODEVIEW	The symbols are in Microsoft CodeView format.
DEBUG_SYMBOL_TYPE_PDB	Symbols in PDB format have been loaded through the pre-Debug Interface Access (DIA) interface.
DEBUG_SYMBOL_TYPE_EXPORT	No actual symbol files were found; symbol information was extracted from the binary file's export table.
DEBUG_SYMBOL_TYPE_DEFERRED	The module was loaded, but the engine has deferred its loading of the symbols.
DEBUG_SYMBOL_TYPE_SYM	Symbols in SYM format have been loaded.
DEBUG_SYMBOL_TYPE_DIA	Symbols in PDB format have been loaded through the DIA interface.

ImageNameSize

The size of the file name for the module. The size is measured in characters, including the terminator.

ModuleNameSize

The size of the module name of the module. The size is measured in characters, including the terminator.

LoadedImageNameSize

The size of the loaded image name for the module. The size is measured in characters, including the terminator.

SymbolFileNameSize

The size of the symbol file name for the module. The size is measured in characters, including the terminator.

MappedImageNameSize

The size of the mapped image name of the module. The size is measured in characters, including the terminator.

Reserved

Reserved for system use.

Remarks

This structure is returned by [GetModuleParameters](#).

To locate the different names for the module, use [GetModuleNameString](#).

For more information about modules, see [Modules](#). For details about the different names for the module, see [GetModuleNameString](#).

Requirements

Header DbgEng.h (include DbgEng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

DEBUG_OUTCTL_XXX

The DEBUG_OUTCTL_XXX constants are used for output control. The constants form a bit field that specifies the current policy of where to send output. The bit field is divided into two sections.

The lower bits must be exactly one of the following values.

Value	Description
DEBUG_OUTCTL_THIS_CLIENT	Output generated by methods called by this client will be sent only to this client's output callbacks .
DEBUG_OUTCTL_ALL_CLIENTS	Output will be sent to all clients.
DEBUG_OUTCTL_ALL_OTHER_CLIENTS	Output will be sent to all clients (except to the client that generated the output).
DEBUG_OUTCTL_IGNORE	Output will be discarded immediately and will not be logged or sent to callbacks.
DEBUG_OUTCTL_LOG_ONLY	Output will be logged but not sent to callbacks.

The higher bits of the bit field may contain the following values.

Value	Description
DEBUG_OUTCTL_NOT_LOGGED	Do not put output from this client in the global log file.
DEBUG_OUTCTL_OVERRIDE_MASK	Sends output to clients regardless of whether the client's output mask allows it.
DEBUG_OUTCTL_DML	For output that supports Debugger Markup Language (DML), sends the output in DML format.

To create a valid output control bit-field, take exactly one value from the first table, along with zero or more values from the second table, and combine them by using the bitwise-OR operator.

The default value of the output control bit-field is DEBUG_OUTCTL_ALL_CLIENTS.

As an alternative to creating your own output control bit-field, you can use one of the following values.

Value	Description
DEBUG_OUTCTL_AMBIENT_DML	Sets the new output control to the same value as the current output control and specifies that the output will be in DML format.
DEBUG_OUTCTL_AMBIENT_TEXT	Sets the new output control to the same value as the current output control and specifies that the output will be in text format.
DEBUG_OUTCTL_AMBIENT	Same as DEBUG_OUTCTL_AMBIENT_TEXT.

Requirements

Header DbgEng.h (include DbgEng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

DEBUG_OUTPUT_XXX

The DEBUG_OUTPUT_XXX constants are output flags. The output flags form a bit field that indicates the type of the output that accompanies them.

The possible values include the following.

Constant	Description
----------	-------------

DEBUG_OUTPUT_NORMAL	Normal output.
DEBUG_OUTPUT_ERROR	Error output.
DEBUG_OUTPUT_WARNING	Warnings.
DEBUG_OUTPUT_VERBOSE	Additional output.
DEBUG_OUTPUT_PROMPT	Prompt output.
DEBUG_OUTPUT_PROMPT_REGISTERS	Register dump before prompt.
DEBUG_OUTPUT_EXTENSION_WARNING	Warnings specific to extension operation.
DEBUG_OUTPUT_DEBUGGEE	Debug output from the target (for example, OutputDebugString or DbgPrint).
DEBUG_OUTPUT_DEBUGGEE_PROMPT	Debug input expected by the target (for example, DbgPrompt).
DEBUG_OUTPUT_SYMBOLS	Symbol messages (for example, !sym noisy).

Requirements

Header DbgEng.h (include DbgEng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

DEBUG_PROCESS_XXX

The process options are a bit set that control how the [debugger engine](#) treats user-mode [processes](#). Some of these process options are global; others are specific to a process.

The process options only apply to live user-mode debugging.

Bit-flag	Description
DEBUG_PROCESS_DETACH_ON_EXIT	(Windows XP and later) The debugger automatically detaches itself from the target process when the debugger exits. This is a global setting.
DEBUG_PROCESS_ONLY_THIS_PROCESS	(Windows XP and later) The debugger will not debug child processes that are created by this process.

Requirements

Header DbgEng.h (include DbgEng.h)

See also

[.childdbg](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

DEBUG_REGISTER_DESCRIPTION structure

The **DEBUG_REGISTER_DESCRIPTION** structure is returned by [GetDescription](#) to describe a processor's register.

Syntax

```
C++
typedef struct _DEBUG_REGISTER_DESCRIPTION {
    ULONG Type;
    ULONG Flags;
    ULONG SubregMaster;
    ULONG SubregLength;
    ULONG64 SubregMask;
    ULONG SubregShift;
    ULONG Reserved0;
} DEBUG_REGISTER_DESCRIPTION, *PDEBUG_REGISTER_DESCRIPTION;
```

Members

Type

The type of value that this register holds. The possible values are the same as for the **Type** field in the [DEBUG_VALUE](#) structure.

Flags

A bit field of flags for the register. Currently, the only bit that can be set is **DEBUG_REGISTER_SUB_REGISTER**, which indicates that this register is a subregister.

SubregMaster

The index of the register of which this register is a sub-register. This field is only used if the DEBUG_REGISTER_SUB_REGISTER bit is set in **Flags**; otherwise, it is set to zero.

SubregLength

The size, in bits, of this sub-register. This field is only used if the DEBUG_REGISTER_SUB_REGISTER bit is set in **Flags**; otherwise, it is set to zero.

SubregMask

The bit mask that converts the register specified in **SubregMaster** into this sub-register. This field is only used if the DEBUG_REGISTER_SUB_REGISTER bit is set in **Flags**; otherwise, it is set to zero.

SubregShift

The bit shift that converts the register specified in **SubregMaster** into this sub-register. This field is only used if the DEBUG_REGISTER_SUB_REGISTER bit is set in **Flags**; otherwise, it is set to zero.

Reserved0

Reserved for system use.

Remarks

If this register is a subregister, the value of the full register can be turned into the value of the sub-register by first shifting **SubregShift** bits to the right and then combining the result with **SubregMask** using the bitwise-AND operator. The size of the sub-register (**SubregLength**) is the number of bits set in **SubregMask**.

For general information about registers, see [Registers](#).

DEBUG_SPECIFIC_FILTER_PARAMETERS structure

The DEBUG_SPECIFIC_FILTER_PARAMETERS structure contains the parameters for a [specific event filter](#).

Syntax

```
C++
typedef struct _DEBUG_SPECIFIC_FILTER_PARAMETERS {
    ULONG ExecutionOption;
    ULONG ContinueOption;
    ULONG TextSize;
    ULONG CommandSize;
    ULONG ArgumentSize;
} DEBUG_SPECIFIC_FILTER_PARAMETERS, *PDEBUG_SPECIFIC_FILTER_PARAMETERS;
```

Members**ExecutionOption**

The [break status](#) of the specific event filter. For possible values, see **DEBUG_FILTER_XXX**.

ContinueOption

The [handling status](#) of the specific event filter. For possible values, see **DEBUG_FILTER_XXX**.

TextSize

The size, in characters (including the terminator), of the name of the specific event filter.

CommandSize

The size, in characters, of the command (including the terminator), to execute when the event occurs.

ArgumentSize

Specifies the size, in characters, of the specific event filter argument. This size includes the NULL terminator. If the specific event filter does not take an argument, **ArgumentSize** is zero.

Note If the filter does take an argument, but the argument is empty, **ArgumentSize** will be one, reflecting the NULL terminator.

Requirements

Header DbgEng.h (include DbgEng.h)

DEBUG_STACK_FRAME structure

The DEBUG_STACK_FRAME structure describes a stack frame and the address of the current instruction for the stack frame.

Syntax

```
C++
typedef struct _DEBUG_STACK_FRAME {
    ULONG64 InstructionOffset;
    ULONG64 ReturnOffset;
    ULONG64 FrameOffset;
    ULONG64 StackOffset;
    ULONG64 FuncTableEntry;
    ULONG64 Params[4];
    ULONG64 Reserved[6];
    BOOL Virtual;
    ULONG FrameNumber;
} DEBUG_STACK_FRAME, *PDEBUG_STACK_FRAME;
```

Members

InstructionOffset

The location in the process's virtual address space of the related instruction for the stack frame. This is typically the return address for the next stack frame, or the current instruction pointer if the frame is at the top of the stack.

ReturnOffset

The location in the process's virtual address space of the return address for the stack frame. This is typically the related instruction for the previous stack frame.

FrameOffset

The location in the process's virtual address space of the stack frame, if known. Some processor architectures do not have a frame or have more than one. In these cases, the engine chooses a value most representative for the given level of the stack.

StackOffset

The location in the process's virtual address space of the processor stack.

FuncTableEntry

The location in the target's virtual address space of the function entry for this frame, if available. When set, this pointer is not guaranteed to remain valid indefinitely and should not be held for future use. Instead, save the value of **InstructionOffset** and use it with [IDebugSymbols3::GetFunctionEntryByOffset](#) to retrieve function entry information later.

Params

The values of the first four stack slots that are passed to the function, if available. If there are less than four arguments, the remaining entries are set to zero. These stack slots are not guaranteed to contain parameter values. Some calling conventions and compiler optimizations might interfere with identification of parameter information. For more detailed argument information and proper location handling, use [IDebugSymbols::GetScopeSymbolGroup](#) to retrieve the actual parameter symbols.

Reserved

Reserved for future use.

Virtual

The value is set to **TRUE** if this stack frame was generated by the debugger by unwinding. Otherwise, the value is **FALSE** if it was formed from a thread's current context. Typically, this is **TRUE** for the frame at the top of the stack, where **InstructionOffset** is the current instruction pointer.

FrameNumber

The index of the frame. This index counts the number of frames from the top of the call stack. The frame at the top of the stack, representing the current call, has index zero.

Requirements

Header DbgEng.h (include DbgEng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

DEBUG_STACK_FRAME_EX structure

The DEBUG_STACK_FRAME_EX structure describes a stack frame and the address of the current instruction for the stack frame.

Syntax

```
C++
typedef struct _DEBUG_STACK_FRAME {
    ULONG64 InstructionOffset;
    ULONG64 ReturnOffset;
    ULONG64 FrameOffset;
    ULONG64 StackOffset;
    ULONG64 FuncTableEntry;
    ULONG64 Params[4];
    ULONG64 Reserved[6];
    BOOL Virtual;
    ULONG FrameNumber;
    ULONG InlineFrameContext;
    ULONG Reserved1;
} DEBUG_STACK_FRAME, *PDEBUG_STACK_FRAME;
```

Members

InstructionOffset

The location in the process's virtual address space of the related instruction for the stack frame. This is typically the return address for the next stack frame, or the current instruction pointer if the frame is at the top of the stack.

ReturnOffset

The location in the process's virtual address space of the return address for the stack frame. This is typically the related instruction for the previous stack frame.

FrameOffset

The location in the process's virtual address space of the stack frame, if known. Some processor architectures do not have a frame or have more than one. In these cases, the engine chooses a value most representative for the given level of the stack.

StackOffset

The location in the process's virtual address space of the processor stack.

FuncTableEntry

The location in the target's virtual address space of the function entry for this frame, if available. When set, this pointer is not guaranteed to remain valid indefinitely and should not be held for future use. Instead, save the value of **InstructionOffset** and use it with [IDebugSymbols3::GetFunctionEntryByOffset](#) to retrieve function entry information later.

Params

The values of the first four stack slots that are passed to the function, if available. If there are less than four arguments, the remaining entries are set to zero. These stack slots are not guaranteed to contain parameter values. Some calling conventions and compiler optimizations might interfere with identification of parameter information. For more detailed argument information and proper location handling, use [IDebugSymbols::GetScopeSymbolGroup](#) to retrieve the actual parameter symbols.

Reserved

Reserved for future use. Set to NULL.

Virtual

The value is set to **TRUE** if this stack frame was generated by the debugger by unwinding. Otherwise, the value is **FALSE** if it was formed from a thread's current context. Typically, this is **TRUE** for the frame at the top of the stack, where **InstructionOffset** is the current instruction pointer.

FrameNumber

The index of the frame. This index counts the number of frames from the top of the call stack. The frame at the top of the stack, representing the current call, has index zero.

InlineFrameContext

Inline frame context.

Reserved1

Used for alignment purposes. Set to 0.

Requirements

Header DbgEng.h (include DbgEng.h)

DEBUG_STATUS_XXX

The DEBUG_STATUS_XXX status codes have two purposes. They instruct the engine on how execution in the target should proceed, and they are used by the engine to report the execution status of the target.

After an event occurs, the engine can receive several instructions that tell it how execution in the target should proceed. In this case, it acts on the instruction with the highest precedence. Typically, the higher precedence status codes represent less execution for the target.

The values in the following table are reverse ordered by precedence; the values that appear earlier in the table have higher precedence.

Status Code	When reporting	When instructing	Precedence
DEBUG_STATUS_NO_DEBUGGEE	No debugging session is active.	N/A	
DEBUG_STATUS_OUT_OF_SYNC	The debugger communications channel is out of sync.	N/A	
DEBUG_STATUS_WAIT_INPUT	The target is awaiting input from the user.	N/A	
DEBUG_STATUS_TIMEOUT	The debugger communications channel has timed out.	N/A	
DEBUG_STATUS_BREAK	The target is suspended.	Suspend the target.	Highest precedence
DEBUG_STATUS_STEP_INTO	The target is executing a single instruction.	Continue execution of the target for a single instruction.	
DEBUG_STATUS_STEP_BRANCH	The target is executing until the next branch instruction.	Continue execution of the target until the next branch instruction.	
DEBUG_STATUS_STEP_OVER	The target is executing a single instruction or--if that instruction is a subroutine call--subroutine.	Continue execution of the target for a single instruction. If the instruction is a subroutine call, the call is entered and the target is allowed to run until the subroutine returns.	
DEBUG_STATUS_GO_NOT_HANDLED	N/A	Continue execution of the target, flagging the event as not handled.	
DEBUG_STATUS_GO_HANDLED	N/A	Continue execution of the target, flagging the event as handled.	
DEBUG_STATUS_GO	The target is executing normally.	Continue normal execution of the target.	
DEBUG_STATUS_IGNORE_EVENT	N/A	Continue previous execution of the target, ignoring the event.	
DEBUG_STATUS_RESTART_REQUESTED	The target is restarting.	Restart the target.	
DEBUG_STATUS_NO_CHANGE	N/A	No instruction. This value is returned by an event callback method when it does not wish to instruct the engine how to proceed with execution in the target.	Lowest precedence

Note The precedence of the status codes does not follow the numeric values of the constants.

Requirements

Header DbgEng.h (include DbgEng.h)

DEBUG_SYMBOL_XXX

The DEBUG_SYMBOL_XXX constants are used for the symbol flags bit-set. The symbol flags describe (in part) a symbol in a symbol group.

The least significant bits of the symbol flags--the bits found in DEBUG_SYMBOL_EXPANSION_LEVEL_MASK--form a number that represents the expansion depth of the

symbol within the symbol group. The depth of a child symbol is always one more than the depth of its parent symbol. For example, to find the depth of a symbol whose flags are contained in the variable *flags*, use the following statement:

```
depth = flags & DEBUG_SYMBOL_EXPANSION_LEVEL_MASK;
```

The rest of the symbol flags' bit-set can contain the following bit-flags.

Constant	Description
<code>DEBUG_SYMBOL_EXPANDED</code>	The children of the symbol are part of the symbol group.
<code>DEBUG_SYMBOL_READ_ONLY</code>	The symbol represents a read-only variable.
<code>DEBUG_SYMBOL_IS_ARRAY</code>	The symbol represents an array variable.
<code>DEBUG_SYMBOL_IS_FLOAT</code>	The symbol represents a floating-point variable.
<code>DEBUG_SYMBOL_IS_ARGUMENT</code>	The symbol represents an argument passed to a function.
<code>DEBUG_SYMBOL_IS_LOCAL</code>	The symbol represents a local variable in a scope.

Requirements

Header DbgEng.h (include DbgEng.h)

See also

[DEBUG SYMBOL PARAMETERS](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

DEBUG_SYMBOL_ENTRY structure

The DEBUG_SYMBOL_ENTRY structure describes a symbol in a symbol group.

Syntax

```
C++
typedef struct _DEBUG_SYMBOL_ENTRY {
    ULONG64 ModuleBase;
    ULONG64 Offset;
    ULONG64 Id;
    ULONG64 Arg64;
    ULONG   Size;
    ULONG   Flags;
    ULONG   TypeId;
    ULONG   NameSize;
    ULONG   Token;
    ULONG   Tag;
    ULONG   Arg32;
    ULONG   Reserved;
} DEBUG_SYMBOL_ENTRY, *PDEBUG_SYMBOL_ENTRY;
```

Members

ModuleBase

The base address of the module in the target's virtual address space.

Offset

The location of the symbol in the target's virtual address space.

Id

The symbol ID of the symbol. If the symbol ID is not known, **Id** is DEBUG_INVALID_OFFSET.

Arg64

The interpretation of **Arg64** depends on the type of the symbol. If the value is not known, **Arg64** is zero.

Size

The size, in bytes, of the symbol's value. This might not be known or might not completely represent all of the data for a symbol. For example, a function's code might be split among multiple regions and the size only describes one region.

Flags

Symbol entry flags. Currently, no flags are defined.

TypeId

The type ID of the symbol.

NameSize

The size, in characters, of the symbol's name. If the size is not known, **NameSize** is zero.

Token

The managed token of the symbol. If the token value is not known or the symbol does not have a token, **Token** is zero.

Tag

The symbol tag for the type of the symbol. This is a value from the **SymTagEnum** enumeration.

Arg32

The interpretation of **Arg32** depends on the type of the symbol. Currently, the value of **Arg32** is the register that holds the value or a pointer to the value of the symbol. If the symbol is not held in a register, or the register is not known, **Arg32** is zero.

Reserved

Set to zero.

Requirements

Header DbgEng.h (include DbgEng.h, DbgHelp.h, or DbgHelp.h)

DEBUG_SYMBOL_PARAMETERS structure

The **DEBUG_SYMBOL_PARAMETERS** structure describes a symbol in a symbol group.

Syntax

C++

```
typedef struct _DEBUG_SYMBOL_PARAMETERS {
    ULONG64 Module;
    ULONG     TypeId;
    ULONG     ParentSymbol;
    ULONG     SubElements;
    ULONG     Flags;
    ULONG64 Reserved;
} DEBUG_SYMBOL_PARAMETERS, *PDEBUG_SYMBOL_PARAMETERS;
```

Members

Module

The location in the target's virtual address space of the base of the module to which the symbol belongs.

TypeId

The type ID of the symbol.

ParentSymbol

The index within the symbol group of the symbol's parent symbol. If the parent symbol is not known, **ParentSymbol** is DEBUG_ANY_ID.

SubElements

The number of children of the symbol. If this symbol has never been expanded within this symbol group, this number will be an estimate that is based on the symbol's type.

Flags

The symbol flags. See [DEBUG SYMBOL XXX](#) for details.

Reserved

Set to zero.

Requirements

Header DbgEng.h (include DbgEng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

DEBUG_SYMBOL_SOURCE_ENTRY structure

The DEBUG_SYMBOL_SOURCE_ENTRY structure describes a section of the source code and a corresponding region of the target's memory.

Syntax

```
C++
typedef struct _DEBUG_SYMBOL_SOURCE_ENTRY {
    ULONG64 ModuleBase;
    ULONG64 Offset;
    ULONG64 FileNameId;
    ULONG64 EngineInternal;
    ULONG     Size;
    ULONG     Flags;
    ULONG     FileNameSize;
    ULONG     StartLine;
    ULONG     EndLine;
    ULONG     StartColumn;
    ULONG     EndColumn;
    ULONG     Reserved;
} DEBUG_SYMBOL_SOURCE_ENTRY, *PDEBUG_SYMBOL_SOURCE_ENTRY;
```

Members

ModuleBase

The base address, in the target's virtual address space, of the module that the source symbol came from.

Offset

The location of the memory corresponding to the source code in the target's virtual address space.

FileNameId

Identifier for the source code file name. If this information is not available, **FileNameId** is set to zero.

EngineInternal

Reserved for internal debugger engine use.

Size

The size of the region of memory corresponding to the source code. If this information is not available, **Size** is set to one.

Flags

Set to zero.

FileNameSize

The number of characters in the source filename, including the terminator.

StartLine

The line number of the start of the region of source code in the file. The number of the first line in the file is one. If this information is not available, **StartLine** is set to DEBUG_ANY_ID.

EndLine

The line number of the end of the region of source code in the file. The number of the first line in the file is one. If this information is not available, **StartLine** is set to DEBUG_ANY_ID.

StartColumn

The column number of the start of the region of source code. The number of the first column is one. If this information is not available, **StartLine** is set to DEBUG_ANY_ID.

EndColumn

The column number of the end of the region of source code. The number of the first column is one. If this information is not available, **StartLine** is set to DEBUG_ANY_ID.

Reserved

Reserved for future use.

Requirements

Header DbgEng.h (include DbgEng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

DEBUG_THREAD_BASIC_INFORMATION structure

The DEBUG_THREAD_BASIC_INFORMATION structure describes an operating system thread.

Syntax

```
C++  
typedef struct _DEBUG_THREAD_BASIC_INFORMATION {  
    ULONG    Valid;  
    ULONG    ExitStatus;  
    ULONG    PriorityClass;  
    ULONG    Priority;  
    ULONG64 CreateTime;  
    ULONG64 ExitTime;  
    ULONG64 KernelTime;  
    ULONG64 UserTime;  
    ULONG64 StartOffset;  
    ULONG64 Affinity;  
} DEBUG_THREAD_BASIC_INFORMATION, *PDEBUG_THREAD_BASIC_INFORMATION;
```

Members

Valid

A bitset that specifies which other members of the structure contain valid information. A member of the structure is valid if the corresponding bit flag is set in **Valid**.

Flag	Members
DEBUG_TBINFO_EXIT_STATUS	ExitStatus
DEBUG_TBINFO_PRIORITY_CLASS	PriorityClass
DEBUG_TBINFO_PRIORITY	Priority
DEBUG_TBINFO_TIMES	CreateTime, ExitTime, KernelTime, UserTime
DEBUG_TBINFO_START_OFFSET	StartOffset
DEBUG_TBINFO_AFFINITY	Affinity

ExitStatus

The exit code of the thread. If the thread is still running, **ExitStatus** is set to STILL_ACTIVE.

ExitStatus is only valid if the DEBUG_TBINFO_EXIT_STATUS bit flag is set in **Valid**.

PriorityClass

The priority class of the thread. The priority classes are defined by the XXX_PRIORITY_CLASS constants in WinBase.h. For more information about thread priority classes, see the Platform SDK.

PriorityClass is only valid if the DEBUG_TBINFO_PRIORITY_CLASS bit flag is set in **Valid**.

Priority

The priority of the thread relative to the priority class. Some thread priorities are defined by the THREAD_PRIORITY_XXX constants in WinBase.h. For more information about thread priorities, see the Platform SDK.

Priority is only valid if the DEBUG_TBINFO_PRIORITY bit flag is set in **Valid**.

CreateTime

The creation time of the thread.

CreateTime is only valid if the DEBUG_TBINFO_TIMES bit flag is set in **Valid**.

ExitTime

The exit time of the thread.

ExitTime is only valid if the DEBUG_TBINFO_TIMES bit flag is set in **Valid**.

KernelTime

The amount of time the thread has executed in kernel mode.

KernelTime is only valid if the DEBUG_TBINFO_TIMES bit flag is set in **Valid**.

UserTime

The amount of time the thread has executed in user-mode.

UserTime is only valid if the DEBUG_TBINFO_TIMES bit flag is set in **Valid**.

StartOffset

The starting address of the thread.

StartOffset is only valid if the DEBUG_TBINFO_START_OFFSET bit flag is set in **Valid**.

Affinity

The thread affinity mask for the thread in a Symmetric Multiple Processor (SMP) computer. For more information about the thread affinity mask, see the Platform SDK.

Affinity is only valid if the DEBUG_TBINFO_AFFINITY bit flag is set in **Valid**.

Requirements

Header DbgEng.h (include DbgEng.h)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

DEBUG_TYPED_DATA structure

The DEBUG_TYPED_DATA structure describes typed data in the memory of the target.

Syntax

```
C++
typedef struct _DEBUG_TYPED_DATA {
    ULONG64 ModBase;
    ULONG64 Offset;
    ULONG64 EngineHandle;
    ULONG64 Data;
    ULONG   Size;
    ULONG   Flags;
    ULONG   TypeId;
    ULONG   BaseTypeId;
    ULONG   Tag;
    ULONG   Register;
    ULONG64 Internal[9];
} _DEBUG_TYPED_DATA, *PDEBUG_TYPED_DATA;
```

Members

ModBase

The base address of the module, in the target's virtual address space, that contains the typed data.

Offset

The location of the typed data in the target's memory. **Offset** is a virtual memory address unless there are flags present in **Flags** that specify that **Offset** is a physical memory address.

EngineHandle

Set to zero.

Data

The data cast to a ULONG64. If **Flags** does not contain the DEBUG_TYPED_DATA_IS_IN_MEMORY flag, the data is not available and **Data** is set to zero.

Size

The size, in bytes, of the data.

Flags

The flags describing the target's memory in which the data resides. The following bit flags can be set.

Flag	Description
DEBUG_TYPED_DATA_IS_IN_MEMORY	The data is in the target's memory and is available.
DEBUG_TYPED_DATA_PHYSICAL_DEFAULT	Offset is a physical memory address, and the physical memory at Offset uses the default memory caching.
DEBUG_TYPED_DATA_PHYSICAL_CACHED	Offset is a physical memory address, and the physical memory at Offset is cached.
DEBUG_TYPED_DATA_PHYSICAL_UNCACHED	Offset is a physical memory address, and the physical memory at Offset is uncached.
DEBUG_TYPED_DATA_PHYSICAL_WRITE_COMBINED	Offset is a physical memory address, and the physical memory at Offset is write-combined.

TypeId

The type ID for the data's type.

BaseTypeId

For generated types, the type ID of the type on which the data's type is based. For example, if the typed data represents a pointer (or an array), **BaseTypeId** is the type of the object pointed to (or held in the array).

For other types, **BaseTypeId** is the same as **TypeId**.

Tag

The symbol tag of the typed data. This is a value from the **SymTagEnum** enumeration. For descriptions of the values, see the DbgHelp API documentation.

Register

The index of the processor's register containing the data, or zero if the data is not contained in a register. (Note that the zero value can represent either that the data is not in a register or that it is in the register whose index is zero.)

Internal

Internal [debugger engine](#) data.

Remarks

Instances of this structure should be manipulated using the [DEBUG_REQUEST_EXT_TYPED_DATA_ANSI Request](#) operation. In particular, instances should be created and released using this method, and members of this structure should not be changed directly.

There is one exception to the preceding rule: the **EXT_TDOP_SET_FROM_TYPE_ID_AND_U64** and **EXT_TDOP_SET_PTR_FROM_TYPE_ID_AND_U64** suboperations take a DEBUG_TYPED_DATA instance that is not manipulated using the **Request** method. These suboperations take a manually created instance with some members manually filled in.

Note Include WdbgExts.h before including DbgEng.h. Additionally, **SymTagEnum** is defined in DbgHelp.h (include DbgHelp.h).

Requirements

Header WdbgExts.h (include WdbgExts.h)

See also

[DEBUG_REQUEST_EXT_TYPED_DATA_ANSI Request](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

DEBUG_TYPEOPTS_XXX

The type options affect how the engine formats numbers and strings for output.

The options are represented by a bit-set with the following bit flags.

Constant	Description
DEBUG_TYPEOPTS_UNICODE_DISPLAY	When this bit is set, USHORT pointers and arrays are output as Unicode characters.
DEBUG_TYPEOPTS_LONGSTATUS_DISPLAY	This is equivalent to the debugger command .enable_unicode 1 . When this bit is set, LONG integers are output in the default base instead of decimal.
DEBUG_TYPEOPTS_FORCE_RADIX_OUTPUT	This is equivalent to the debugger command .enable_long_status 1 . When this bit is set, integers (except for LONG integers) are output in the default base instead of decimal.
	This is equivalent to the debugger command .force_radix_output 1 .

Remarks

By default, all of the type formatting options are turned off.

For more information about types, see [Types](#).

DEBUG_VALUE structure

The DEBUG_VALUE structure holds register and expression values.

Syntax

```

C++
typedef struct _DEBUG_VALUE {
    union {
        UCHAR I8;
        USHORT I16;
        ULONG I32;
        struct {
            ULONG64 I64;
            BOOL Nat;
        };
        float F32;
        double F64;
        UCHAR F80Bytes[10];
        UCHAR F82Bytes[11];
        UCHAR F128Bytes[16];
        UCHAR VI8[16];
        USHORT VI16[8];
        ULONG VI32[4];
        ULONG64 VI64[2];
        float VF32[4];
        double VF64[2];
        struct {
            ULONG LowPart;
            ULONG HighPart;
        } I64Parts32;
        struct {
            ULONG64 LowPart;
            LONG64 HighPart;
        } F128Parts64;
        UCHAR RawBytes[24];
    };

Remarks

The **Type** field specifies the value type that is being held by the structure. This also specifies which field in the structure is valid. The possible values of the **Type** field, and the corresponding field specified as valid in the structure, include the following.

Type Name	Type	Valid DEBUG_VALUE Field
DEBUG_VALUE_INT8	8-bit signed integer	I8
DEBUG_VALUE_INT16	16-bit signed integer	I16
DEBUG_VALUE_INT32	32-bit signed integer	I32
DEBUG_VALUE_INT64	64-bit signed integer	I64
DEBUG_VALUE_FLOAT32	32-bit floating point number	F32
DEBUG_VALUE_FLOAT64	64-bit floating point number	F64
DEBUG_VALUE_FLOAT80	80-bit floating point number	F80Bytes
DEBUG_VALUE_FLOAT128	128-bit floating point number	F128Bytes
DEBUG_VALUE_VECTOR64	64-bit vector	VI8[8], VI16[4], VI32[2], VI64[1], VF32[2], VF64[1]
DEBUG_VALUE_VECTOR128	128-bit vector	VI8[16], VI16[8], VI32[4], VI64[2], VF32[4], VF64[2]

EXT_TDOP enumeration

The EXT_TDOP enumeration is used in the **Operation** member of the [EXT_TYPED_DATA](#) structure to specify which suboperation the [DEBUG_REQUEST_EXT_TYPED_DATA_ANSI Request](#) operation will perform.

Syntax

```
C++
typedef enum _EXT_TDOP {
    EXT_TDOP_COPY,
    EXT_TDOP_RELEASE,
    EXT_TDOP_SET_FROM_EXPR,
    EXT_TDOP_SET_FROM_U64_EXPR,
    EXT_TDOP_GET_FIELD,
    EXT_TDOP_EVALUATE,
    EXT_TDOP_GET_TYPE_NAME,
    EXT_TDOP_OUTPUT_TYPE_NAME,
    EXT_TDOP_OUTPUT_SIMPLE_VALUE,
    EXT_TDOP_OUTPUT_FULL_VALUE,
    EXT_TDOP_HAS_FIELD,
    EXT_TDOP_GET_FIELD_OFFSET,
    EXT_TDOP_GET_ARRAY_ELEMENT,
    EXT_TDOP_GET_DEREFERENCE,
    EXT_TDOP_GET_TYPE_SIZE,
    EXT_TDOP_OUTPUT_TYPE_DEFINITION,
    EXT_TDOP_GET_POINTER_TO,
    EXT_TDOP_SET_FROM_TYPE_ID_AND_U64,
    EXT_TDOP_SET_PTR_FROM_TYPE_ID_AND_U64,
    EXT_TDOP_COUNT
} EXT_TDOP;
```

Constants**EXT_TDOP_COPY**

Makes a copy of a typed data description.

EXT_TDOP_RELEASE

Releases a typed data description.

EXT_TDOP_SET_FROM_EXPR

Returns the value of an expression.

EXT_TDOP_SET_FROM_U64_EXPR

Returns the value of an expression. An optional address can be provided as a parameter to the expression.

EXT_TDOP_GET_FIELD

Returns a member of a structure.

EXT_TDOP_EVALUATE

Returns the value of an expression. An optional value can be provided as a parameter to the expression.

EXT_TDOP_GET_TYPE_NAME

Returns the type name for typed data.

EXT_TDOP_OUTPUT_TYPE_NAME

Prints the type name for typed data.

EXT_TDOP_OUTPUT_SIMPLE_VALUE

Prints the value of typed data.

EXT_TDOP_OUTPUT_FULL_VALUE

Prints the type and value for typed data.

EXT_TDOP_HAS_FIELD

Determines whether a structure contains a specified member.

EXT_TDOP_GET_FIELD_OFFSET

Returns the offset of a member within a structure.

EXT_TDOP_GET_ARRAY_ELEMENT

Returns an element from an array.

EXT_TDOP_GET_DEREFERENCE

Dereferences a pointer, returning the value it points to.

EXT_TDOP_GET_TYPE_SIZE

Returns the size of the specified typed data.

EXT_TDOP_OUTPUT_TYPE_DEFINITION

Prints the definition of the type for the specified typed data.

EXT_TDOP_GET_POINTER_TO

Returns a new typed data description that represents a pointer to specified typed data.

EXT_TDOP_SET_FROM_TYPE_ID_AND_U64

Creates a typed data description from a type and memory location.

EXT_TDOP_SET_PTR_FROM_TYPE_ID_AND_U64

Creates a typed data description representing a pointer to a specified memory location with specified type.

EXT_TDOP_COUNT

Does not specify an operation. Instead, it represents the number of suboperations defined in the EXT_TDOP enumeration.

Requirements

Header WdbgExts.h (include WdbgExts.h or DbgEng.h)

[EXT_TYPED_DATA](#)
[DEBUG_REQUEST_EXT_TYPED_DATA_ANSI](#)

[Request](#)[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

EXT_TYPED_DATA structure

The EXT_TYPED_DATA structure is passed to and returned from the [DEBUG REQUEST EXT TYPED DATA ANSI Request](#) operation. It contains the input and output parameters for the operation as well as specifying which particular suboperation to perform.

Syntax

```
C++
typedef struct _EXT_TYPED_DATA {
    EXT_TDOP          Operation;
    ULONG             Flags;
    DEBUG_TYPED_DATA InData;
    DEBUG_TYPED_DATA OutData;
    ULONG             InStrIndex;
    ULONG             In32;
    ULONG             Out32;
    ULONG64           In64;
    ULONG64           Out64;
    ULONG             StrBufferIndex;
    ULONG             StrBufferChars;
    ULONG             StrCharsNeeded;
    ULONG             DataBufferIndex;
    ULONG             DataBufferBytes;
    ULONG             DataBytesNeeded;
    HRESULT           Status;
    ULONG64           Reserved[8];
} EXT_TYPED_DATA, *PEXT_TYPED_DATA;
```

Members

Operation

Specifies which suboperation the [DEBUG REQUEST EXT TYPED DATA ANSI Request](#) operation should perform. The interpretation of some of the other members depends on **Operation**. For a list of possible suboperations, see [EXT_TDOP](#).

Flags

Specifies the bit flags describing the target's memory in which the data resides. If no flags are present, the data is considered to be in virtual memory. One of the following flags may be present:

Flag	Description
EXT_TDF_PHYSICAL_DEFAULT	The typed data is in physical memory, and this physical memory uses the default memory caching.
EXT_TDF_PHYSICAL_CACHED	The typed data is in physical memory, and this physical memory is cached.
EXT_TDF_PHYSICAL_UNCACHED	The typed data is in physical memory, and this physical memory is uncached.
EXT_TDF_PHYSICAL_WRITE_COMBINED	The typed data is in physical memory, and this physical memory is write-combined.

InData

Specifies typed data to be used as input to the operation. For details about this structure, see [DEBUG TYPED DATA](#).

The interpretation of **InData** depends on the value of **Operation**.

OutData

Receives typed data as output from the operation. Any suboperation that returns typed data to **OutData** initially copies the contents of **InData** to **OutData**, then modifies **OutData** in place, so that the input parameters in **InData** are also present in **OutData**. For details about this structure, see [DEBUG TYPED DATA](#).

The interpretation of **OutData** depends on the value of **Operation**.

InStrIndex

Specifies the position of an ANSI string to be used as input to the operation. **InStrIndex** can be zero to indicate that the input parameters do not include an ANSI string.

The position of the string is relative to the base address of this EXT_TYPED_DATA structure. The string must follow this structure, so **InStrIndex** must be greater than the size of this structure. The string is part of the input to the operation and **InStrIndex** must be smaller than *InBufferSize*, the size of the input buffer passed to [Request](#).

The interpretation of the string depends on the value of **Operation**.

In32

Specifies a 32-bit parameter to be used as input to the operation.

The interpretation of **In32** depends on the value of **Operation**.

Out32

Receives a 32-bit value as output from the operation.

The interpretation of **Out32** depends on the value of **Operation**.

In64

Specifies a 64-bit parameter to be used as input to the operation.

The interpretation of **In64** depends on the value of **Operation**.

Out64

Receives a 64-bit value as output from the operation.

The interpretation of **Out64** depends on the value of **Operation**.

StrBufferIndex

Specifies the position to return an ANSI string as output from the operation. **StrBufferIndex** can be zero if no ANSI string is to be received from the operation.

The position of the string is relative to the base address of the returned EXT_TYPED_DATA structure. The string must follow the structure, so **StrBufferIndex** must be greater than the size of this structure. The string is part of the output from the suboperation, and **StrBufferIndex** plus **StrBufferChars** must be smaller than **OutBufferSize**, the size of the output buffer passed to [Request](#).

The interpretation of the string depends on the value of **Operation**.

StrBufferChars

Specifies the size in characters of the ANSI string buffer specified by **StrBufferIndex**.

StrCharsNeeded

Receives the number of characters needed by the string buffer specified by **StrBufferIndex**.

DataBufferIndex

Set to zero.

DataBufferBytes

Set to zero.

DataBytesNeeded

Set to zero,

Status

Receives the status code returned by the operation. This is the same value returned by [Request](#).

Reserved

Set to zero.

Remarks

The members of this structure are used as the input and output parameters to the [DEBUG_REQUEST_EXT_TYPED_DATA_ANSI Request](#) operation. The interpretation of most of the parameters depends on the particular suboperation being performed, as specified by the **Operation** member.

This structure can optionally specify additional data--using the members **InStrIndex** and **StrBufferIndex**--that is included with the structure. This additional data is specified relative to the address of the instance of this structure. When used with the [DEBUG_REQUEST_EXT_TYPED_DATA_ANSI Request](#) operation, the additional data is included in the **InBuffer** and **OutBuffer** (as appropriate) and should be included in the size of these two buffers.

Requirements

HRESULT Values

The following is a list of common return values for functions and methods, and their usual meanings.

Successful results. These values are defined in WinError.h.

S_OK

Successful completion.

S_FALSE

Completed without error, but only partial results were obtained.

If a buffer is not large enough to hold the information that is returned to it, the returned information is often truncated to fit into the buffer and S_FALSE is returned from the method.

Error results. These values are defined in WinError.h.

E_FAIL

The operation could not be performed.

E_INVALIDARG

One of the arguments passed in was invalid.

E_NOINTERFACE

The object searched for was not found.

E_OUTOFMEMORY

A memory allocation attempt failed.

E_UNEXPECTED

The target was not accessible, or the engine was not in a state where the function or method could be processed.

E_NOTIMPL

Not implemented.

HRESULT_FROM_WIN32(ERROR_ACCESS_DENIED)

The operation was denied because the debugger is in [Secure Mode](#).

NT error results. Other error codes, such as STATUS_CONTROL_C_EXIT and STATUS_NO_MORE_ENTRIES, can sometimes occur. These results are passed to the HRESULT_FROM_NT macro that is defined in WinError.h before being returned.

Win32 error results. Other error codes, such as ERROR_READFAULT and ERROR_WRITEFAULT, can sometimes occur. These results are passed to the HRESULT_FROM_WIN32 macro that is defined in WinError.h before being returned.

Requirements

Header DbgEng.h (include DbgEng.h)

Specific Exceptions

The following table lists the exception codes for the specific exception filters.

Exception Code	Exception	Header file or value
STATUS_ACCESS_VIOLATION	Access violation	NtStatus.h
STATUS_ASSERTION_FAILURE	Assertion failure	NtStatus.h
STATUS_APPLICATION_HANG	Application hang	0xFFFFFFFF

STATUS_BREAKPOINT	Break instruction exception	NtStatus.h
STATUS_CPP_EH_EXCEPTION	C++ exception handling exception	0xE06D7363
STATUS_CLR_EXCEPTION	Common language runtime (CLR) exception	0xE0434f4D
DBG_CONTROL_BREAK	CTRL+Break exception	NtStatus.h
DBG_CONTROL_C	CTRL+C exception	NtStatus.h
STATUS_DATATYPE_MISALIGNMENT	Data misaligned	NtStatus.h
DBC_COMMAND_EXCEPTION	Debugger command exception	NtStatus.h
STATUS_GUARD_PAGE_VIOLATION	Guard page violation	NtStatus.h
STATUS_ILLEGAL_INSTRUCTION	Illegal instruction	NtStatus.h
STATUS_IN_PAGE_ERROR	In-page I/O error	NtStatus.h
STATUS_INTEGER_DIVIDE_BY_ZERO	Integer divide-by-zero	NtStatus.h
STATUS_INTEGER_OVERFLOW	Integer overflow	NtStatus.h
STATUS_INVALID_HANDLE	Invalid handle	NtStatus.h
STATUS_INVALID_LOCK_SEQUENCE	Invalid lock sequence	NtStatus.h
STATUS_INVALID_SYSTEM_SERVICE	Invalid system call	NtStatus.h
STATUS_PORT_DISCONNECTED	Port disconnected	NtStatus.h
STATUS_SINGLE_STEP	Single-step exception	NtStatus.h
STATUS_STACK_BUFFER_OVERRUN	Stack buffer overflow	NtStatus.h
STATUS_STACK_OVERFLOW	Stack overflow	NtStatus.h
STATUS_VERIFIER_STOP	Application Verifier stop	NtStatus.h
STATUS_WAKE_SYSTEM_DEBUGGER	Wake debugger	NtStatus.h

SYMBOL_INFO_EX structure

The SYMBOL_INFO_EX structure describes the extended line symbol information.

Syntax

```
C++
typedef struct _SYMBOL_INFO_EX {
    ULONG     SizeOfStruct;
    ULONG     TypeOfInfo;
    ULONG64   Offset;
    ULONG     Line;
    ULONG     Displacement;
    ULONG     Reserved[4];
} SYMBOL_INFO_EX, *PSYMBOL_INFO_EX;
```

Members

SizeOfStruct

Set to sizeof(SYMBOL_INFO_EX).

TypeOfInfo

Type of the symbol information stored. DEBUG_SYMBOL_BREAKPOINT_SOURCE_LINE is the only supported type.

Offset

Address of the first line that does not correspond to compiler added glue line.

Line

First line number that does not correspond to a compiler added glue line.

Displacement

Line displacement: Offset between given address and the first instruction of the line.

Reserved[4]

Reserved for future use. This parameter can be set to any value.

Remarks

Glue lines are code lines added to the binary by the compiler/linker. Glue lines do not have corresponding lines in the original source code. They are added to bind together

functionality inside of the PE generated binary, for example calling .NET framework functions inside of a native binary.

Anatomy of a DbgEng Extension DLL

A DbgEng extension DLL exports a number of callback functions, some of which may be implementations of extension commands.

These extension DLLs are loaded by the [debugger engine](#) and can provide extra functionality or automation of tasks while performing user-mode or kernel-mode debugging on Microsoft Windows.

If you performed a full install of Debugging Tools for Windows, a sample DbgEng extension called "exts" can be found in the sdk\samples\exts subdirectory of the installation directory.

Extension Commands

An extension DLL may export any number of functions that are used to execute extension commands. Each function is explicitly declared as an export in the .def file, and its name must consist entirely of lowercase letters.

Functions used to implement extension commands must match the prototype [**PDEBUG_EXTENSION_CALL**](#).

These functions are named according to the standard C++ convention, except that uppercase letters are not permitted. The exported function name and the extension command name are identical, except that the extension command begins with an exclamation point (!). For example, when you load myextension.dll into the debugger and then type !stack into the Debugger Command window, the debugger looks for an exported function named stack in myextension.dll.

If myextension.dll is not already loaded, or if there may be other extension commands with the same name in other extension DLLs, you can type !myextension.stack into the Debugger Command window to indicate the extension DLL and the extension command in that DLL.

Other Exported Functions

A DbgEng extension DLL must export [**DebugExtensionInitialize**](#). This will be called when the DLL is loaded, to initialize the DLL. It may be used by the DLL to initialize global variables.

An extension DLL may export [DebugExtensionUninitialize](#). If this is exported, it will be called before the extension DLL is unloaded. It may be used by the DLL to clean up before it is unloaded.

An extension DLL may export [DebugExtensionNotify](#). If this is exported, it will be called when a session begins or ends, and when a target starts or stops executing. These notifications are also provided to [IDebugEventCallbacks](#) objects registered with a client.

An extension DLL may export [KnownStructOutput](#). If this is exported, it will be called when the DLL is loaded. This function returns a list of structures that the DLL knows how to print on a single line. It may be called later to format instances of these structures for printing.

Engine Procedure for Loading a DbgEng Extension DLL

When an extension DLL is loaded, the callback functions are called by the engine in the following order:

1. **DebugExtensionInitialize** is called so the extension DLL can initialize.
2. If exported, **DebugExtensionNotify** is called if the engine has an active session, and called again if the session is suspended and accessible.
3. If exported, **KnownStructOutput** is called to request a list of structures the DLL knows how to print on a single line.

See [Loading Debugger Extension DLLs](#) for information about how to use the debugger to load and unload an extension DLL, and see [Using Debugger Extension Commands](#) for information about executing an extension command.

The debugger engine will place a **try / except** block around a call to an extension DLL. This protects the engine from some types of bugs in the extension code; but, since the extension calls are executed in the same thread as the engine, they can still cause it to crash.

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

Using Clients and the Engine

A DbgEng extension interacts with the [debugger engine](#) through a client object.

When an extension function is called, it is passed a client. The extension function should use this client for all its interaction with the debugger engine, unless it has a specific reason to use another client.

An extension library may create its own client object upon initialization by using [DebugCreate](#). This client can be used to register callback objects from the DLL.

Note Care should be taken when modifying the client passed to an extension function. In particular, registering callbacks with this client could disrupt the input, output, or event handling of the debugger. It is recommended that a new client be created to register callbacks.

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

Writing DbgEng Extension Code

[DbgEng extension](#) commands can include any standard C++ code. They can also include the C++ interfaces that appear in the dbgeng.h header file, in addition to the C functions that appear in the wdbgexts.h header file.

If you intend to use functions from wdbgexts.h, you need to define KDEXT_64BIT before wdbgexts.h is included. For example:

```
#define KDEXT_64BIT
#include "wdbgexts.h"
#include "dbgeng.h"
```

For a full list of interfaces in dbgeng.h that can be used in an extension command, see [Debugger Engine Reference](#).

For a full list of functions in wdbgexts.h that can be used in an extension command, see [WdbgExts Functions](#). A number of these functions appear in 32-bit versions and 64-bit versions. Typically, the 64-bit versions end in "64" and the 32-bit versions have no numerical ending -- for example, **ReadIoSpace64** and **ReadIoSpace**. When calling a wdbgexts.h function from a DbgEng extension, you should always use the function name ending in "64". This is because the [debugger engine](#) always uses 64-bit pointers internally, regardless of the target platform.

If you include wdbgexts.h in your DbgEng extension, you should call [GetWindbgExtensionApis64](#) during the initialization of your extension DLL (see [DebugExtensionInitialize](#)).

Note You must not attempt to call any DbgHelp or ImageHlp routines from any debugger extension. Calling these routines is not supported and may cause a variety of problems.

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

Building DbgEng Extensions

All debugger extensions should be compiled and built by using Visual Studio. The Build utility is no longer used with debugger extensions.

For documentation on the Building projects in Visual Studio refer to [Building C++ Projects in Visual Studio](#).

To build an extension, use the following procedure:

► To build a debugger extension

1. Open the **dbg sdk.sln** sample project in Visual Studio.
2. Check the include and lib file project settings. If %debuggers% represents the root of your Debugging Tools for Windows installation, they should be set as follows:

```
Include Path  
%debuggers%\sdk\inc  
Library Path  
%debuggers%\sdk\lib
```

If you have moved these headers and libraries to a different location, specify that location instead.

3. Select **Build** and then **Build Solution** from the menu in Visual Studio.

DebugExtensionInitialize callback function

The **DebugExtensionInitialize** callback function is called by the engine after loading a DbgEng extension *DLL*.

Syntax

```
C++
HRESULT DebugExtensionInitialize(
    _Out_ PULONG Version,
    _Out_ PULONG Flags
);
```

Parameters

Version [out]

Receives the version of the extension. The high 16 bits contain the major version number, and the low 16 bits contain the minor version number.

Flags [out]

Set this to zero. (Reserved for future use.)

Return value

Return code	Description
S_OK	The extension was successfully initialized.

Any other value indicates that the extension DLL was unable to initialize and the engine will unload it.

Remarks

The engine looks for this function by name in each extension DLL. This function must be exported by a DbgEng extension DLL.

The version number can be set by using the macro DEBUG_EXTENSION_VERSION found in dbgeng.h, for example:

```
*Version = DEBUG_EXTENSION_VERSION(Major, Minor)
```

Implementations of this function should initialize any global variables required by the extension DLL.

There may or may not be a session active when this function is called, so the extension should not assume that it is able to query session information.

The function type is defined as PDEBUG_EXTENSION_INITIALIZE in dbgeng.h.

Requirements

Target platform [Universal](#)
 Header Dbgeng.h

See also

[DebugExtensionUninitialize](#)
[DebugExtensionNotify](#)
[KnownStructOutput](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

DebugExtensionNotify callback function

The engine calls the **DebugExtensionNotify** callback function to inform the extension DLL when a session changes its active or accessible status.

Syntax

```
C++
void CALLBACK DebugExtensionNotify(
    _In_ ULONG Notify,
    _In_ ULONG64 Argument
);
```

Parameters

Notify [in]

Can be any of the following values:

Value	Description
-------	-------------

DEBUG_NOTIFY_SESSION_ACTIVE	A debugging session is active. The session may not necessarily be suspended.
DEBUG_NOTIFY_SESSION_INACTIVE	No debugging session is active.
DEBUG_NOTIFY_SESSION_ACCESSIBLE	The debugging session has suspended and is now accessible.
DEBUG_NOTIFY_SESSION_INACCESSIBLE	The debugging session has started running and is now inaccessible.

Argument [in]

Set to zero. (Reserved for future use.)

Return value

This callback function does not return a value.

Remarks

This function is optional. A DbgEng extension DLL only needs to export **DebugExtensionNotify** if it wants to be notified when the session state changes. The engine looks for this function by name in the extension DLL.

This function allows the extension DLL to cache information about the session without needing to register explicit callbacks. It is called at the beginning and end of a session, and each time a target starts or stops executing.

After the extension DLL is initialized, the engine will use this function to notify the DLL if it has started a session. If the current session is suspended, the engine will call this function a second time to notify the DLL that the session is accessible.

Requirements

Target platform [Universal](#)

Header Dbgeng.h

DebugExtensionProvideValue callback function

The **DebugExtensionProvideValue** callback function sets [pseudo-register](#) values.

Syntax

```
C++
HRESULT CALLBACK DebugExtensionProvideValue(
    _In_     PDEBUG_CLIENT Client,
    _In_     ULONG       Flags,
    _In_     PCWSTR      Name,
    _Out_    PULONG64    Value,
    _Out_    PULONG64    TypeModBase,
    _Out_    PULONG      TypeId,
    _Out_    PULONG      TypeFlags
);
```

Parameters

Client [in]

A client to use if the extension needs DbgEng functions.

Flags [in]

Provides behavioral flags. This parameter is currently reserved.

Name [in]

The name of the value to return. This name might be one of the names that the [DebugExtensionQueryValueNames](#) function returned or a name that the caller might already be aware of.

Value [out]

A pointer to the value to be set.

TypeModBase [out]

The base starting address for *Client*.

TypeId [out]

A pointer to the ID for the type of *Value*.

TypeFlags [out]

A parameter that you can use to return one of the following flags:

Value	Meaning
DEBUG_EXT_PVTYPE_IS_VALUE	The value that is pointed to by <i>Value</i> is not a pointer.
DEBUG_EXT_PVTYPE_IS_POINTER	The value that is pointed to by <i>Value</i> is an address for a pointer to data of the type that <i>TypeModBase</i> and <i>TypeId</i> specify.

Return value

DebugExtensionProvideValue might return one of the following values:

Return code	Description
S_OK	The function was successfully completed.

This function might also return error values. For more information about possible return values, see [Return Values](#).

Remarks

The name that the *Name* parameter specifies must start with \$\$ and have a terminating NULL character.

Requirements

Target platform

Header Dbgeng.h

DebugExtensionQueryValueNames callback function

The **DebugExtensionQueryValueNames** callback function recovers [pseudo-register](#) values.

Syntax

```
C++
HRESULT CALLBACK DebugExtensionQueryValueNames (
    _In_     PDEBUG_CLIENT Client,
    _In_     ULONG       Flags,
    _Out_    PWSTR        Buffer,
    _In_     ULONG       BufferChars,
    _Out_    PULONG      BufferNeeded
);
```

Parameters

Client [in]

A client to use if the extension needs DbgEng functions.

Flags [in]

Provides behavioral flags. This parameter is currently reserved.

Buffer [out]

A string buffer that the caller provides, to be filled with the set of value names that the client wants to expose.

BufferChars [in]

The count of wide characters in *Buffer*.

BufferNeeded [out]

The number of wide characters that this function needs to complete successfully.

Return value

DebugExtensionQueryValueNames might return one of the following values:

Return code	Description
S_OK	The function was successfully completed.
S_FALSE	The function completed without error, but it obtained only partial results.

This function might also return error values. For more information about possible return values, see [Return Values](#).

Remarks

Value names must start with \$\$ and have a terminating NULL character. The *Buffer* string must also be NULL-terminated. For example, *Buffer* could be "\$\$myval1\0\$\$myval2\0\0".

Requirements

Target platform

Header Dbgeng.h

DebugExtensionUninitialize callback function

The **DebugExtensionUninitialize** callback function is called by the engine to uninitialized the DbgEng extension DLL before it is unloaded.

Syntax

C++

```
void CALLBACK DebugExtensionUninitialize(void);
```

Parameters

This callback function has no parameters.

Return value

This callback function does not return a value.

Remarks

This function is optional. A DbgEng extension DLL only needs to export **DebugExtensionUninitialize** if it needs to be notified before it is unloaded. The engine looks for this function by name in the extension DLL.

This function can be used by the extension DLL to clean up before it is unloaded.

There may or may not be a session active when this function is called, so the extension should not assume that it is able to query session information.

KnownStructOutput callback function

The engine calls the *KnownStructOutput* callback function to request information about structures that the extension DLL can format for printing. The engine calls this function for the following reasons.

- Get a list of structures that the DLL can format for printing.
- Get a single-line representation of a particular structure.
- Ask whether a particular structure should have its name printed along with its single-line representation.

Syntax

```
C++
HRESULT CALLBACK KnownStructOutput(
  _In_     ULONG   Flag,
  _In_     ULONG64 Address,
  _In_     PSTR    StructName,
  _Out_    PSTR    Buffer,
  _Inout_  PULONG  BufferSize
);
```

Parameters

Flag [in]

One of the following values, depending on what information the engine wants to obtain from the extension DLL.

Value	Description
DEBUG_KNOWN_STRUCT_GET_NAMES	Get a list of structure names.
DEBUG_KNOWN_STRUCT_SUPPRESS_TYPE_NAME	Ask whether a structure should have its name printed.
DEBUG_KNOWN_STRUCT_GET_SINGLE_LINE_OUTPUT	Get a single-line representation of a structure.

Address [in]

When getting a list of names: Unused.

When asking whether a name should be printed: Unused.

When getting a single-line representation: Specifies the location in the target's memory address space of the structure to be printed.

StructName [in]

When getting a list of names: Unused.

When asking whether a name should be printed: Specifies the name of the structure. This is one of the names returned from the DEBUG_KNOWN_STRUCT_GET_NAMES query.

When getting a single-line representation: Specifies the name of the structure. This is one of the names returned from the DEBUG_KNOWN_STRUCT_GET_NAMES query.

Buffer [out]

When getting a list of names: Receives a list of the names of the structures that the extension can format for printing. One null character must appear between each pair of names. The list must be terminated with two null characters. The number of characters written to this buffer must not exceed the value of *BufferSize*.

When asking whether a name should be printed: Unused.

When getting a single-line representation: Receives a representation of the structure, identified by *StructName* and *Address*, as a string. The number of characters written to this buffer must not exceed the value of *BufferSize*.

BufferSize [in, out]

When getting a list of names: On input, specifies the size, in characters, of *Buffer*. On output, if the buffer is too small, receives the required buffer size.

When asking whether a name should be printed: Unused.

When getting a single-line representation: On input, specifies the size, in characters, of *Buffer*. On output, if the buffer is too small, receives the required buffer size.

Return value

Return code	Description
S_OK	<p>When getting a list of names: <i>Buffer</i> contains the requested list of names.</p> <p>When asking whether a name should be printed: The printing of the name should be suppressed. That is, the name should not be printed.</p> <p>When getting a single-line representation: <i>Buffer</i> contains the requested single-line representation.</p> <p>When getting a list of names: <i>BufferSize</i> was too small on input. On output, <i>BufferSize</i> contains the required buffer size.</p>
S_FALSE	<p>When asking whether a name should be printed: The printing of the name should not be suppressed. That is, the name should be printed.</p> <p>When getting a single-line representation: <i>BufferSize</i> was too small on input. On output, <i>BufferSize</i> contains the required buffer size.</p>

All other return values indicate that the function failed. The engine will continue ignoring the contents of *Buffer*.

Remarks

This function is optional. An extension DLL only needs to export **KnownStructOutput** if it has the ability to format special structures for printing on a single line. The engine looks for this function by name in the extension DLL.

After initializing the extension DLL, the engine calls this function to query the DLL for the list of structure names it knows how to print. Then, whenever the engine prints a summary of one of the structures whose name is in the list, it calls this function to format the structure for printing.

Requirements

Target platform

Header Dbgeng.h

PDEBUG_EXTENSION_CALL function pointer

Callback functions of the type **PDEBUG_EXTENSION_CALL** are called by the engine to execute [extension commands](#). You can give these functions any name you want, as long as it contains no uppercase letters.

Syntax

```

C++
typedef HRESULT ( CALLBACK *PDEBUG_EXTENSION_CALL) (
    _In_     PDEBUG_CLIENT Client,
    _In_opt_ PCSTR        Args
);

```

Parameters

Client [in]

Specifies an interface pointer to the client. This can be used to interact with the engine. Typically, this is the client through which the extension command was issued.

Args [in, optional]

Specifies the arguments passed to the extension command. In particular, if the extension command was called from a command line, *Args* contains the rest of the command line. It can be **NULL** or empty.

Return value

Return code	Description
S_OK	The function was successful.
DEBUG_EXTENSION_CONTINUE_SEARCH	Indicates that the function cannot handle the command, or that other implementations of the same command in other extension DLLs should also run. The engine should continue searching other extension DLLs for another function to handle the command. For example, this can be used to have all help functions run if each one returns CONTINUE_SEARCH.

All other return values are ignored by the engine.

Remarks

The name of the function becomes the name of the extension command. When executing an extension command, the engine searches through each of the loaded extension DLLs in turn, looking for an exported function that has the same name as the command. For example, when executing the command !stack, the engine will look for an exported function named **stack** in each loaded extension DLL. For information about the order in which extension DLLs are searched, see [Using Debugger Extension Commands](#).

The extension function should use the client that was passed to it in *Client* for all interaction with the engine, unless it has a specific reason to use another client. The extension function should not maintain the pointer to the client object after it has finished.

Requirements

Target platform

Header Dbgeng.h

EngExtCpp Extension Libraries

An EngExtCpp extension library is a DLL that uses the EngExtCpp extension framework found in EngExtCpp.h. When this library is loaded by the debugger engine, its methods and functions can provide extra functionality or automation of tasks while performing user-mode or kernel-mode debugging on Microsoft Windows.

The EngExtCpp extension framework is built on top of the [DbgEng extension framework](#). It offers the same debugger engine API for interaction with the debugger engine, but it also provides additional features to make common tasks simpler.

If you performed a full install of Debugging Tools for Windows, a sample EngExtCpp extension called "extcpp" can be found in the sdk\samples\extcpp subdirectory of the installation directory.

EXT_CLASS and ExtExtension

At the core of an EngExtCpp extension library is a single instance of the [EXT_CLASS](#) class. An EngExtCpp extension library will provide the implementation of this class, which contains all the extension commands and methods for formatting structures that are exported by the library.

EXT_CLASS is a subclass of [ExtExtension](#). The single instance of this class is created using the [EXT_DECLARE_GLOBALS](#) macro which must appear exactly once in the source files for the extension library.

When the extension library is loaded, the [Initialize](#) method of the class is called by the engine, and the [Uninitialize](#) method is called before unloading the class. Additionally, the methods [OnSessionActive](#), [OnSessionInactive](#), [OnSessionAccessible](#), and [OnSessionInaccessible](#) are called by the engine to notify the extension library of the state of the debugging session.

Extension Commands

The [EXT_CLASS](#) class can contain a number of methods that are used to execute extension commands. Each extension command is declared in the EXT_CLASS class by using the [EXT_COMMAND_METHOD](#) macro. The implementation of a command is defined by using the [EXT_COMMAND](#) macro.

Known Structures

The [EXT_CLASS](#) class can contain a number of methods that use the [ExtKnownStructMethod](#) prototype. The methods can be used by the engine to format instances of certain structure types for output.

Provided Values

The [EXT_CLASS](#) class can contain a number of methods that use the [ExtProvideValueMethod](#) prototype. The methods can be used by the engine to evaluate some pseudo-registers provided by the extension.

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

Client Objects and the Engine

An EngExtCpp extension interacts with the [debugger engine](#) through a client object. Interface pointers to the client object are available to the extension through members of the [ExtExtension](#) base class. The following members provide access to the first version of the engine API interfaces.

Engine API interface ExtExtension member

IDebugAdvanced	m_Advanced
IDebugClient	m_Client
IDebugControl	m_Control
IDebugDataSpaces	m_Data
IDebugRegisters	m_Registers
IDebugSymbols	m_Symbols
IDebugSystemObjects	m_System

The following members provide access to later versions of the engine API interfaces. These interfaces may not be available in all versions of the debugger engine. If they are not available, any attempt to use them will result in an exception being thrown.

Engine API interface ExtExtension member

IDebugAdvanced2	m_Advanced2
IDebugAdvanced3	m_Advanced3
IDebugClient2	m_Client2
IDebugClient3	m_Client3
IDebugClient4	m_Client4
IDebugClient5	m_Client5
IDebugControl2	m_Control2
IDebugControl3	m_Control3
IDebugControl4	m_Control4
IDebugData2	m_Data2
IDebugData3	m_Data3

IDebugData4	m_Data4
IDebugRegisters2	m_Registers2
IDebugSymbols2	m_Symbols2
IDebugSymbols3	m_Symbols3
IDebugSystemObjects2	m_System2
IDebugSystemObjects3	m_System3
IDebugSystemObjects4	m_System4

The members in these tables are initialized each time the extension library is used to execute an extension command or format a structure for output. Once a task is completed, these members are uninitialized. Consequently, extensions should not cache the values of these members and should use the **ExtExtension** members directly.

An extension library can also create its own client objects using the method [IDebugClient::CreateClient](#) or the functions [DebugCreate](#) or [DebugConnect](#).

For an overview of client objects, see [Client Objects](#).

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

Writing EngExtCpp Extensions

The EngExtCpp extension library can include any standard C++ code. It can also include the C++ interfaces that appear in the engextcpp.h and dbgeng.h header files, in addition to the C functions that appear in the wdbgexts.h header file. Both dbgeng.h and wdbgexts.h are included from engextcpp.h.

For a full list of interfaces in dbgeng.h that can be used in an extension command, see [Debugger Engine Reference](#).

For a full list of functions in wdbgexts.h that can be used in an extension command, see [WdbgExts Functions](#). A number of these functions appear in 32-bit versions and 64-bit versions. Typically, the 64-bit versions end in "64" and the 32-bit versions have no numerical ending -- for example, [ReadIoSpace64](#) and [ReadIoSpace](#). When calling a wdbgexts.h function from a DbgEng extension, you should always use the function name ending in "64". This is because the [debugger engine](#) always uses 64-bit pointers internally, regardless of the target platform. When including wdbgexts.h, engextcpp.h selects the 64-bit version of the API. The [ExtensionApis](#) global variable used by the WDbgExts API is automatically initialized on entry to a EngExtCpp method and cleared on exit.

When an EngExtCpp extension is used with remote DbgEng interfaces, the WDbgExts interfaces will not be available and the [ExtensionApis](#) structure can be zeroed. If an EngExtCpp extension is expected to function in such an environment, it should avoid using the WDbgExts API.

Note You must not attempt to call any DbgHelp or ImageHlp routines from any debugger extension. Calling these routines is not supported and may cause a variety of problems.

Building EngExtCpp Extensions

The EngExtCpp extension libraries are built almost the same way as the DbgEng extension libraries. For more information, see [Building DbgEng Extensions](#).

The EngExtCpp implementation code (engextcpp.cpp) is used instead of linking with a static library.

Because the EngExtCpp extension framework is built on top of the DbgEng extension framework, an EngExtCpp extension DLL should export the same functions as a DbgEng extension DLL.

Each extension should be exported. When you use the [EXT_COMMAND](#) macro to define an extension function, this macro also creates a C function with the same name as the extension. This function should be exported from the DLL.

The following functions are provided by engextcpp should be exported from the EngExtCpp DLL.

- **DebugExtensionInitialize** -- so that the [Initialize](#) method can be called to initialize the library.
- **DebugExtensionUninitialize** -- so that the [Uninitialize](#) method can be called to uninitialized the library.
- **KnownStructOutputEx** -- so that the engine can call the [ExtKnownStructMethod](#) methods to format known structures for output.
- **DebugExtensionNotify** -- so that the engine can call the [OnSessionActive](#), [OnSessionInactive](#), [OnSessionAccessible](#), and [OnSessionInaccessible](#) methods to notify the extension library of changes to the debugging session's state.
- **help** -- so that the EngExtCpp extension framework can automatically provide a !help extension.

These functions can be exported even if the functionality they provide is not needed. Moreover, if they are not exported, the functionality they provide will be lost.

DebugExtensionInitialize must be exported in order for the debugger engine to recognize the DLL as a valid DbgEng extension DLL.

Parsing Extension Arguments

The EngExtCpp extension framework provides methods to aid in parsing the command-line arguments passed to an extension. To take advantage of these methods, the extension must first declare the format of the command-line arguments in the [**EXT_COMMAND**](#) macro.

To bypass the command-line argument parsing done by the framework and let the extension itself parse the arguments, set the command-line description to "`{}{{custom}}`" and use the method [**GetRawArgStr**](#) to get the command-line arguments for parsing.

Command-line description strings will automatically be wrapped when printed, to fit the column width of the display. However, newline characters can be embedded in the description strings - using '\n' - to start new lines.

The command-line description can be **NULL** or the empty string. If either occurs, it indicates that the extension command does not take any arguments.

Command-Line Description

The description of the command-line arguments is a sequence that contains two types of components: directives and arguments. The description can optionally contain one of each directive and can contain up to 64 arguments.

Directives

Directives specify how the arguments are parsed. They are enclosed by double braces ('{}' and '{}'). Each directive can optionally appear zero or one times in the string that describes the arguments.

The following directives are available:

`custom`

Turns off the parsing done by the extension framework and lets the extension perform its own parsing.

`l:str`

Overrides the default long description of the command-line arguments. The extension framework will use `str` for the full description of all the arguments.

`opt:str`

Overrides the default prefix characters for named commands. The default value is "/-", allowing '/' or '-' to be used as the prefix that identifies named arguments.

`s:str`

Overrides the default short description of the command-line arguments. The extension framework will use `str` for the short description of all the arguments.

Here are some examples of directives. The following string is used by an extension command that parses its own arguments. It also provides short and long descriptions for use with the automatic **!help** extension command:

`{}{{custom}}{}{{s:<arg1> <arg2>}}{}{{l:arg1 - Argument 1\narg2 - Argument 2}}`

The following string changes the argument option prefix characters to '/' or '-'. With this directive, the arguments will be specified using '+arg' and ':arg' instead of '/arg' and '-arg':

`{}{{opt:+:}}`

Arguments

Arguments can be of two types: named and unnamed. Unnamed arguments are read positionally. Both types of argument also have a display name, used by the help command.

Argument descriptions are enclosed by single braces ('{}' and '{}').

Each argument description has the following syntax:

`{[optname];[type[,flags]];[argname];[argdesc]}`

where:

`optname`

The name of the argument. This is the name used in commands and in methods that fetch arguments by name. This name is optional. If it is present, the argument becomes a "named argument"; it can appear anywhere on the command-line and is referenced by name. If it is not present, the argument becomes an "unnamed argument"; its position on the command-line is important and it is referenced by its position relative to the other unnamed arguments.

`type`

The type of the argument. This affects how the argument is parsed and how it is retrieved. The *type* parameter can have one of the following values:

b

Boolean type. The argument is either present or not present. Named Boolean arguments can be retrieved using [HasArg](#).

e[d][s][bits]

Expression type. The argument has a numeric value. Named expression arguments can be retrieved using [GetArgU64](#) and unnamed expression arguments can be retrieved using [GetUnnamedArgU64](#).

d

The expression is limited to the next space character in the argument string. If this is not present, the expression evaluator will consume characters from the command line until it determines that it reached the end of the expression.

s

The value of the expression is signed. Otherwise, the value of the expression is unsigned.

bits

The number of bits in the value of the argument. The maximum value for *bits* is 64.

s

String type. The string is limited to the next space character. Named string arguments can be retrieved using [GetArgStr](#) and unnamed string arguments can be retrieved using [GetUnnamedArgStr](#).

x

String type. The argument is the rest of the command line. The argument is retrieved using [GetArgStr](#) or [GetUnnamedArgStr](#), as with the s string type.

flags

The argument flags. These determine how the argument will be treated by the parser. The *flags* parameter can have one of the following values:

d=expr

The default value of the argument. If the argument is not present on the command line, then the argument is set to *expr*. The default value is a string that is parsed according to the type of the argument.

ds

The default value will not be displayed in the argument description provided by the help.

o

The argument is optional. This is the default for named arguments.

r

The argument is required. This is the default for unnamed arguments.

argname

The display name of the argument. This is the name used by the automatic **!help** extension command and by the automatic **/?** or **-?** command-line arguments. Used when printing a summary of the command-line options.

argdesc

A description of the argument. This is the description printed by the automatic **!help** extension and by the automatic **"/?"** or **"-?"** command-line arguments.

Here are some examples of argument descriptions. The following expression defines a command which takes a single optional expression argument. The argument must fit in 32 bits. If the argument isn't present on the command line, the default value of 0x100 will be used.

```
(;e32,o,d=0x100;flags;Flags to control command)
```

The following expression defines a command with an optional Boolean "/v" argument and a required unnamed string argument.

```
(v;b;;Verbose mode){;s;name;Name of object}
```

The following expression defines a command that has an optional named expression argument **/oname expr** and an optional named string argument **/eol str**. If **/eol** is present, its value will be set to the remainder of the command line and no further arguments will be parsed.

```
(oname;e;expr;Address of object){eol;x;str;Commands to use}
```

Command Line

The following is a list of some ways that arguments are parsed on the command line:

- The values of named expression and string arguments follow the name on the command line. For example, **/name expr** or **/name str**.
- For named Boolean arguments, the value is true if the name appears on the command line; false otherwise.

- Multiple single-character-named Boolean options can be grouped together on the command line. For example, "/a /b /c" can be written using the shorthand notation "/abc" (unless there is already an argument named "abc").
- If the command line contains the named argument "?" - for example, "/" and "-?" - the argument parsing ends, and the help text for the extension is displayed.

Parsing Internals

Several methods are used by the argument parser to set arguments.

The method [SetUnnamedArg](#) will change the value of an unnamed argument. And, for convenience, the methods [SetUnnamedArgStr](#) and [SetUnnamedArgU64](#) will set unnamed string and expression arguments respectively.

Similar methods exist for named arguments. [SetArg](#) is used to change the value of any named argument and [SetArgStr](#) and [SetArgU64](#) are used for named string and expression arguments respectively.

Typed Data

The EngExtCpp extension framework provides a few classes to help manipulate the target's memory. The [ExtRemoteData](#) class describes a small piece of the target's memory. If the type of this memory is known, it is referred to as *typed data* and is described by [ExtRemoteTyped](#) objects.

Windows lists can be iterated over by using [ExtRemoteList](#) and, if the type of the objects in the list is known, [ExtRemoteTypedList](#).

Note Like the client objects in [ExtExtension](#), instances of these classes are only valid while the extension library is used to execute an extension command or format a structure for output. In particular, they should not be cached. For more information about when client objects are valid, see [Client Objects and the Engine](#).

Remote Data

Remote data should be handled using the class [ExtRemoteData](#). This class is a wrapper around a small section of a target's memory. [ExtRemoteData](#) automatically retrieves the memory and wraps other common requests with throwing methods.

Remote Typed Data

If the type of the remote data is known, it should be handled using the [ExtRemoteTyped](#) class. This class is an enhanced remote data object that understands data typed with type information from symbols. It is initialized to a particular object by symbol or cast, after which it can be used like an object of the given type.

Remote Lists

To handle remote lists, use the [ExtRemoteList](#) class. This class can be used for either a singly linked or doubly linked list. If the list is doubly linked, it is assumed that the previous pointer immediately follows the next pointer. The class contains methods that can iterate over the list and retrieve nodes both forward and backward. [ExtRemoteList](#) can be used with either null-terminated or circular lists also.

Remote Typed Lists

To handle remote lists when the type of the nodes in the list is known, use the [ExtRemoteTypedList](#) class. This is an enhanced version of [ExtRemoteList](#). In addition to the basic functionality of [ExtRemoteList](#), [ExtRemoteTypedList](#) automatically determines link offsets from type information.

EXT_CLASS

The EXT_CLASS constant specifies the name of the C++ class that represents the EngExtCpp extension library.

```
#ifndef EXT_CLASS
#define EXT_CLASS Extension
#endif
```

Remarks

The default value of EXT_CLASS is **Extension**. You can change this value by defining EXT_CLASS before you include the header file Engextcpp.hpp.

Each extension command in the library is declared as a member of the class EXT_CLASS using the macro [EXT_COMMAND_METHOD](#). For example, a library with two extension commands, **extcmd** and **anotherextcmd**, could define the class EXT_CLASS as follows:

```
class EXT_CLASS : public ExtExtension
{
public:
    EXT_COMMAND_METHOD(extcmd);
    EXT_COMMAND_METHOD(anotherextcmd);
}
```

Extension commands that have been declared by using EXT_COMMAND_METHOD should be defined by using [EXT_COMMAND](#) and should be exported from the library.

The [EXT_DECLARE_GLOBALS](#) macro creates a single instance of the EXT_CLASS class.

Requirements

Header Engextcpp.h (include Engextcpp.hpp)

See also

[EXT_COMMAND](#)
[EXT_COMMAND_METHOD](#)
[EXT_DECLARE_GLOBALS](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

EXT_COMMAND_METHOD function

The EXT_COMMAND_METHOD macro declares an extension command from inside the definition of the [EXT_CLASS](#) class.

Syntax

```
C++
EXT_COMMAND_METHOD(
    _Name
);
```

Parameters

Name

The name of the extension command. As with all extension commands, the name must consist entirely of lowercase letters.

Remarks

This macro must be used inside the definition of the [EXT_CLASS](#) class.

The macro [EXT_COMMAND](#) should be used to define the extension command. As with all C++ declarations, the EXT_COMMAND_METHOD declaration should appear in the source files before the EXT_COMMAND definition.

Requirements

Target platform

Header Engextcpp.h (include Engextcpp.hpp)

See also

[EXT_CLASS](#)
[EXT_COMMAND](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

EXT_COMMAND function

The EXT_COMMAND macro is used to define an extension command that was declared by using the [EXT_COMMAND_METHOD](#) macro.

An extension command is defined as follows:

Syntax

```
C++
EXT_COMMAND(
    _Name,
    _Desc,
    _Args
);
```

Parameters

Name

The name of the extension command. This must be the same as the Name parameter that is used to declare the extension command by using [EXT_COMMAND_METHOD](#).

Because EXT_COMMAND is a macro, Name must be the bare name of the extension command and should not be enclosed in quotation marks or be a variable.

Desc

A string describing the extension command.

Args

A string describing the arguments that are expected by the extension command. For information about how the Args string is formatted, see [Parsing Extension Arguments](#).

Note As an alternative to supplying a string that describes the arguments, you can use the string "`{custom}`" to indicate that the extension command will parse the arguments itself. The method [GetRawArgStr](#) can be used to fetch the raw argument for parsing.

Remarks

The body of the extension command does not take any arguments. However, because the extension command is declared as a method of the [EXT_CLASS](#) class, it has access to all the members of the [ExtExtension](#) base class, some of which are initialized for the execution of the extension command.

The macro [EXT_COMMAND_METHOD](#) should be used to declare the extension command. As with all C++ declarations, the EXT_COMMAND_METHOD declaration should appear in the source files before the EXT_COMMAND definition.

When the debugger engine calls an extension command method, it wraps the call in a `try / except` block. This protects the engine from some types of bugs in the extension code; but, since the extension calls are executed in the same thread as the engine, they can still cause it to crash.

This macro also creates a function called Name (which calls the method defined by the macro). In order for the engine to call the extension, this function must be exported from the extension library DLL.

Requirements

Target platform

Header Engextcpp.h (include Engextcpp.hpp)

See also

[EXT_CLASS](#)
[EXT_COMMAND_METHOD](#)
[ExtExtension](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

EXT_DECLARE_GLOBALS

The EXT_DECLARE_GLOBALS macro sets up some global variables for use by the EngExtCpp extension framework. This include creating a single instance of the [EXT_CLASS](#) class that represents the EngExtCpp extension library.

One of the source files to be compiled into the EngExtCpp extension library should include the following command

```
EXT_DECLARE_GLOBALS()
```

Requirements

Header Engextcpp.h (include Engextcpp.hpp)

```

Members

m_ExtMajorVersion

The major version number of the extension library. This should be set by the [Initialize](#) method. If it is not set, it defaults to 1.

m_ExtMinorVersion

The minor version number of the extension library. This should be set by the [Initialize](#) method. If it is not set, it defaults to 0 (zero).

m_ExtInitFlags

The DbgEng extension initialization flags for [DebugExtensionInitialize](#).

m_KnownStructs

An array of [ExtKnownStruct](#) structures that the extension library is capable of formatting for output. This member should be set by the [Initialize](#) method and should not be changed once this method returns.

If **m_KnownStructs** is not NULL, the **TypeName** member of the last [ExtKnownStruct](#) structure in the array must be **NULL**.

When formatting a target's structure for output, if the name of the structure's type matches the **TypeName** member of one of the [ExtKnownStruct](#) structures in this array, the callback function specified in the **Method** member is called to perform the formatting.

m_ProvidedValues

An array of [ExtProvidedValue](#) structures listing the pseudo registers that the extension library can provide values for. This member should be set by the [Initialize](#) method and should not be changed once this method returns.

If **m_ProvidedValues** is not NULL, the **ValueName** member of the last [ExtProvidedValue](#) structure in the array must be **NULL**.

When evaluating a pseudo register, if the name of the pseudo register matches the **ValueName** member of one of the [ExtProvidedValue](#) structures in this array, the callback function specified in the **Method** member is called to evaluate the pseudo register.

m_Advanced

The [IDebugAdvanced](#) interface pointer for the client object that can be used by the extension library. It is valid during the invocation of externally-called extension methods-for example, the execution of an extension command, a call to [ExtKnownStructMethod](#) and [ExtProvideValueMethod](#).

m_Client

The [IDebugClient](#) interface pointer for the client object that can be used by the extension library. It is valid during the invocation of externally-called extension methods-for example, the execution of an extension command, a call to [ExtKnownStructMethod](#) and [ExtProvideValueMethod](#).

m_Control

The [IDebugControl](#) interface pointer for the client object that can be used by the extension library. It is valid during the invocation of externally-called extension methods-for example, the execution of an extension command, a call to [ExtKnownStructMethod](#) and [ExtProvideValueMethod](#).

m_Data

The [IDebugDataSpaces](#) interface pointer for the client object that can be used by the extension library. It is valid during the invocation of externally-called extension methods-for example, the execution of an extension command, a call to [ExtKnownStructMethod](#) and [ExtProvideValueMethod](#).

m_Registers

The [IDebugRegisters](#) interface pointer for the client object that can be used by the extension library. It is valid during the invocation of externally-called extension methods-for example, the execution of an extension command, a call to [ExtKnownStructMethod](#) and [ExtProvideValueMethod](#).

m_Symbols

The [IDebugSymbols](#) interface pointer for the client object that can be used by the extension library. It is valid during the invocation of externally-called extension methods-for example, the execution of an extension command, a call to [ExtKnownStructMethod](#) and [ExtProvideValueMethod](#).

m_System

The [IDebugSystemObjects](#) interface pointer for the client object that can be used by the extension library. It is valid during the invocation of externally-called extension methods-for example, the execution of an extension command, a call to [ExtKnownStructMethod](#) and [ExtProvideValueMethod](#).

m_Advanced2

The [IDebugAdvanced2](#) interface pointer for the client object that can be used by the extension library. It is valid during the invocation of externally-called extension methods-for example, the execution of an extension command, a call to [ExtKnownStructMethod](#) and [ExtProvideValueMethod](#). This interface might not be available in all versions of the debugger engine.

m_Advanced3

The [IDebugAdvanced3](#) interface pointer for the client object that can be used by the extension library. It is valid during the invocation of externally-called extension methods-for example, the execution of an extension command, a call to [ExtKnownStructMethod](#) and [ExtProvideValueMethod](#). This interface might not be available in all versions of the debugger engine.

m_Client2

The [IDebugClient2](#) interface pointer for the client object that can be used by the extension library. It is valid during the invocation of externally-called extension methods-for example, the execution of an extension command, a call to [ExtKnownStructMethod](#) and [ExtProvideValueMethod](#). This interface might not be available in all versions of the debugger engine.

m_Client3

The [IDebugClient3](#) interface pointer for the client object that can be used by the extension library. It is valid during the invocation of externally-called extension methods-for example, the execution of an extension command, a call to [ExtKnownStructMethod](#) and [ExtProvideValueMethod](#). This interface might not be available in all versions of the debugger engine.

m_Client4

The [IDebugClient4](#) interface pointer for the client object that can be used by the extension library. It is valid during the invocation of externally-called extension methods-for example, the execution of an extension command, a call to [ExtKnownStructMethod](#) and [ExtProvideValueMethod](#). This interface might not be available in all versions of the debugger engine.

m_Client5

The [IDebugClient5](#) interface pointer for the client object that can be used by the extension library. It is valid during the invocation of externally-called extension methods-for example, the execution of an extension command, a call to [ExtKnownStructMethod](#) and [ExtProvideValueMethod](#). This interface might not be available in all versions of the debugger engine.

m_Control2

The [IDebugControl2](#) interface pointer for the client object that can be used by the extension library. It is valid during the invocation of externally-called extension methods-for example, the execution of an extension command, a call to [ExtKnownStructMethod](#) and [ExtProvideValueMethod](#). This interface might not be available in all versions of the debugger engine.

m_Control3

The [IDebugControl3](#) interface pointer for the client object that can be used by the extension library. It is valid during the invocation of externally-called extension methods-for example, the execution of an extension command, a call to [ExtKnownStructMethod](#) and [ExtProvideValueMethod](#). This interface might not be available in all versions of the debugger engine.

m_Control4

The [IDebugControl4](#) interface pointer for the client object that can be used by the extension library. It is valid during the invocation of externally-called extension methods-for example, the execution of an extension command, a call to [ExtKnownStructMethod](#) and [ExtProvideValueMethod](#). This interface might not be available in all versions of the debugger engine.

m_Data2

The [IDebugDataSpaces2](#) interface pointer for the client object that can be used by the extension library. It is valid during the invocation of externally-called extension methods-for example, the execution of an extension command, a call to [ExtKnownStructMethod](#) and [ExtProvideValueMethod](#). This interface might not be available in all versions of the debugger engine.

m_Data3

The [IDebugDataSpaces3](#) interface pointer for the client object that can be used by the extension library. It is valid during the invocation of externally-called extension methods-for example, the execution of an extension command, a call to [ExtKnownStructMethod](#) and [ExtProvideValueMethod](#). This interface might not be available in all versions of the debugger engine.

m_Data4

The [IDebugDataSpaces4](#) interface pointer for the client object that can be used by the extension library. It is valid during the invocation of externally-called extension methods-for example, the execution of an extension command, a call to [ExtKnownStructMethod](#) and [ExtProvideValueMethod](#). This interface might not be available in all versions of the debugger engine.

m_Registers2

The [IDebugRegisters2](#) interface pointer for the client object that can be used by the extension library. It is valid during the invocation of externally-called extension methods-for example, the execution of an extension command, a call to [ExtKnownStructMethod](#) and [ExtProvideValueMethod](#). This interface might not be available in all versions of the debugger engine.

m_Symbols2

The [IDebugSymbols2](#) interface pointer for the client object that can be used by the extension library. It is valid during the invocation of externally-called extension methods-for example, the execution of an extension command, a call to [ExtKnownStructMethod](#) and [ExtProvideValueMethod](#). This interface might not be available in all versions of the debugger engine.

m_Symbols3

The [IDebugSymbols3](#) interface pointer for the client object that can be used by the extension library. It is valid during the invocation of externally-called extension methods-for example, the execution of an extension command, a call to [ExtKnownStructMethod](#) and [ExtProvideValueMethod](#). This interface might not be available in all versions of the debugger engine.

m_System2

The [IDebugSystemObjects2](#) interface pointer for the client object that can be used by the extension library. It is valid during the invocation of externally-called extension methods-for example, the execution of an extension command, a call to [ExtKnownStructMethod](#) and [ExtProvideValueMethod](#). This interface might not be available in all versions of the debugger engine.

m_System3

The [IDebugSystemObjects3](#) interface pointer for the client object that can be used by the extension library. It is valid during the invocation of externally-called extension methods-for example, the execution of an extension command, a call to [ExtKnownStructMethod](#) and [ExtProvideValueMethod](#). This interface might not be available in all versions of the debugger engine.

m_System4

The [IDebugSystemObjects4](#) interface pointer for the client object that can be used by the extension library. It is valid during the invocation of externally-called extension methods-for example, the execution of an extension command, a call to [ExtKnownStructMethod](#) and [ExtProvideValueMethod](#). This interface might not be available in all versions of the debugger engine.

m_PtrSize

The size of a pointer on the current target. If the target uses 32-bit pointers, **m_PtrSize** is 4. If the target uses 64-bit pointers, **m_PtrSize** is 8.

m_AppendBuffer

A character buffer used to return strings from the extension library to the engine. The size of this buffer is **m_AppendBufferChars**. The methods [AppendBufferString](#), [AppendStringVa](#), and [AppendString](#) can be used to write strings to this buffer.

m_AppendBufferChars

The size, in characters, of the buffer **m_AppendBuffer**.

ExtExtension.Initialize method

The **Initialize** method is called by the engine to initialize an EngExtCpp extension library after loading it.

Syntax

```
C++
virtual HRESULT Initialize();
```

Parameters

This method has no parameters.

Return value

This method can return one of these values.

Return code	Description
S_OK	The extension library was successfully initialized.

Remarks

The extension library version number should be set by this method. This can be done by setting the members **m_ExtMajorVersion** and **m_ExtMinorVersion** of the base class [ExtExtension](#).

The **ExtExtension** member **m_KnownStructs** should be set by this method to indicate to the engine which structures the extension library is capable of formatting for output.

If this method is defined in the extension library class [EXT CLASS](#), it can be used by the extension library to initialize any variables it requires.

There may or may not be a debugging session active when this function is called, so you should not assume that the extension can query session information.

Requirements

Target platform

Header Engextcpp.h (include Engextcpp.hpp)

See also

[EXT CLASS](#)
[ExtExtension](#)
[Uninitialize](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

ExtExtension.Uninitialize method

The **Uninitialize** method is called by the engine to uninitialized an EngExtCpp extension library before it is unloaded.

Syntax

```
C++
virtual void Uninitialize();
```

Parameters

This method has no parameters.

Return value

This method does not return a value.

Remarks

If this method is defined in the extension library class [EXT CLASS](#), it can be used by the extension library to clean up before it is unloaded.

There may or may not be a debugging session active when this function is called, so you should not assume that the extension can query session information.

Requirements

Target platform

Header Engextcpp.h (include Engextcpp.hpp)

See also

[ExtExtension](#)
[EXT CLASS](#)
[Initialize](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

ExtExtension.OnSessionActive method

The **OnSessionActive** method is called by the engine to inform the EngExtCpp extension library when the debugging session becomes active.

Syntax

```
C++
virtual void OnSessionActive(
    [in] ULONG64 Argument
);
```

Parameters

Argument [in]

Set to zero. (Reserved for future use).

Return value

This method does not return a value.

Remarks

The session might not be accessible.

If this method is defined in the extension library class [EXT CLASS](#), it can be used to allow the extension library to cache information about the session without the need to register event callbacks.

This method is called at the beginning of a session and, if a session has already started, after the extension library is initialized.

If a target is suspended, [OnSessionAccessible](#) is called instead.

Requirements

Target platform

Header Engextcpp.hpp (include Engextcpp.hpp)

See also

[ExtExtension](#)
[EXT CLASS](#)
[Initialize](#)
[OnSessionAccessible](#)
[OnSessionInactive](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

ExtExtension.OnSessionInactive method

The **OnSessionInactive** method is called by the engine to inform the EngExtCpp extension library when the debugging session becomes inactive.

Syntax

```
C++
virtual void OnSessionInactive(
    [in] ULONG64 Argument
);
```

Parameters

Argument [in]

Set to zero. (Reserved for future use).

Return value

This method does not return a value.

Remarks

If this method is defined in the extension library class [EXT CLASS](#), it can be used to allow the extension library to cache information about the session without the need to register event callbacks.

This method is called at the end of a session.

Requirements

Target platform

Header Engextcpp.hpp (include Engextcpp.hpp)

See also

[ExtExtension](#)
[EXT CLASS](#)
[OnSessionActive](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

ExtExtension.OnSessionAccessible method

The **OnSessionAccessible** method is called by the engine to inform the EngExtCpp extension library when the debugging session becomes accessible.

Syntax

```
C++
virtual void OnSessionAccessible(
    [in] ULONG64 Argument
);
```

Parameters

Argument [in]

Set to zero. (Reserved for future use).

Return value

This method does not return a value.

Remarks

If this method is defined in the extension library class [EXT_CLASS](#), it can be used to allow the extension library to cache information about the session without the need to register event callbacks.

This method is called when a target is suspended and, if the session is already accessible, after the extension library is initialized (and [OnSessionActive](#) has been called).

Requirements

Target platform

Header Engextcpp.hpp (include Engextcpp.hpp)

See also

[ExtExtension](#)
[EXT_CLASS](#)
[OnSessionActive](#)
[OnSessionInaccessible](#)

[Send comments about this topic to Microsoft](#)

OnSessionInaccessible method

The **OnSessionInaccessible** method is called by the engine to inform the EngExtCpp extension library when the debugging session becomes inaccessible.

Syntax

```
C++
virtual void OnSessionInaccessible(
    [in] ULONG64 Argument
);
```

Parameters

Argument [in]

Set to zero. (Reserved for future use).

Return value

This method does not return a value.

Remarks

If this method is defined in the extension library class [EXT CLASS](#), it can be used to allow the extension library to cache information about the session without the need to register event callbacks.

This method is called when a target starts executing.

Requirements

Target platform

Header Engextcpp.h (include Engextcpp.hpp)

See also

[EXT CLASS](#)
[OnSessionAccessible](#)

ExtExtension.GetNumUnnamedArgs method

The **GetNumUnnamedArgs** method returns the number of unnamed arguments in the command line used to invoke the current extension command.

Syntax

C++

```
ULONG GetNumUnnamedArgs();
```

Parameters

This method has no parameters.

Return value

GetNumUnnamedArgs returns the number of unnamed arguments.

Remarks

The indices of the unnamed arguments returned by **GetNumUnnamedArgs** range from zero to the number of unnamed arguments minus one (unnamed args - 1).

For an overview of argument parsing in the EngExtCpp extensions framework, see [Parsing Extension Arguments](#).

This method should only be called during the execution of an extension command provided by this class.

Requirements

Target platform

Header Engextcpp.h (include Engextcpp.hpp)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

ExtExtension.GetUnnamedArgStr method

The **GetUnnamedArgStr** method returns an unnamed string argument from the command line used to invoke the current extension command.

Syntax

C++

```
PCSTR GetUnnamedArgStr(
    [in] ULONG Index
);
```

Parameters

Index [in]

Specifies the index of the argument. The command-line description used in [EXT_COMMAND](#) must specify that the type of this argument is string. The value of *Index* should be between zero and the number of unnamed arguments returned by [GetNumUnnamedArgs](#) minus one (unnamed arguments - 1).

Return value

[GetUnnamedArgStr](#) returns the unnamed string argument.

Remarks

For an overview of argument parsing in the EngExtCpp extensions framework, see [Parsing Extension Arguments](#).

The string returned by [GetUnnamedArgStr](#) is only meaningful during the execution of the current extension command.

This method should only be called during the execution of an extension command provided by this class.

Requirements

Target platform

Header Engextcpp.hpp (include Engextcpp.hpp)

See also

[ExtExtension](#)
[EXT_COMMAND](#)
[GetNumUnnamedArgs](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

ExtExtension.GetUnnamedArgU64 method

The [GetUnnamedArgU64](#) method returns the value of an unnamed expression argument from the command line used to invoke the current extension command.

Syntax

```
C++
ULONG64 GetUnnamedArgU64(
    [in] ULONG Index
);
```

Parameters

Index [in]

Specifies the index of the argument. The command-line description used in [EXT_COMMAND](#) must specify that the type of this argument is string. *Index* should be between zero and the number of unnamed arguments returned by [GetNumUnnamedArgs](#) minus one (unnamed arguments - 1).

Return value

[GetUnnamedArgU64](#) returns the value of the unnamed expression argument.

Remarks

For an overview of argument parsing in the EngExtCpp extensions framework, see [Parsing Extension Arguments](#).

This method should only be called during the execution of an extension command provided by this class.

Requirements

Target platform

Header Engextcpp.hpp (include Engextcpp.hpp)

See also

[ExtExtension](#)
[EXT_COMMAND](#)
[GetNumUnnamedArgs](#)

[Send comments about this topic to Microsoft](#)

ExtExtension.HasUnnamedArg method

The **HasUnnamedArg** method indicates whether a specified unnamed argument is present in the command line used to invoke the current extension command.

Syntax

```
C++
bool HasUnnamedArg(
    [in] ULONG Index
);
```

Parameters

Index [in]

Specifies the index of the argument. *Index* should be between zero and the number of unnamed arguments returned by [GetNumUnnamedArgs](#) minus one (unnamed arguments - 1).

Return value

HasUnnamedArg returns `true` if the argument is present; `false` if it is not present.

Remarks

This method will work for all types of unnamed arguments. For an overview of argument parsing in the EngExtCpp extensions framework, see [Parsing Extension Arguments](#).

This method should only be called during the execution of an extension command provided by this class.

Requirements

Target platform

Header Engextcpp.hpp (include Engextcpp.hpp)

See also

[ExtExtension](#)
[GetNumUnnamedArgs](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

ExtExtension.GetArgStr method

The **GetArgStr** method returns a named string argument from the command line used to invoke the current extension command.

Syntax

```
C++
PCSTR GetArgStr(
    [in] PCSTR Name,
    [in] bool Required
);
```

Parameters

Name [in]

Specifies the name of the argument. The command-line description used in [EXT_COMMAND](#) must specify that the type of this argument is string.

Required [in]

Specifies if the argument is required. If *Required* is `true` and the argument was not present on the command line, **ExtInvalidArgumentException** is thrown. You do not need to set this parameter; if it is not set *Required* defaults to `true`.

Return value

GetArgStr returns the named string argument.

Remarks

For an overview of argument parsing in the EngExtCpp extensions framework, see [Parsing Extension Arguments](#).

The string returned by **GetArgStr** is only meaningful during the execution of the current extension command.

This method should only be called during the execution of an extension command provided by this class.

Requirements

Target platform

Header Engextcpp.hpp (include Engextcpp.hpp)

See also

[ExtExtension](#)
[EXT_COMMAND](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

ExtExtension.GetArgU64 method

The **GetArgU64** method returns the value of a named expression argument from the command line used to invoke the current extension command.

Syntax

```
C++  
ULONG64 GetArgU64(  
    [in] PCSTR Name,  
    [in] bool Required  
) ;
```

Parameters

Name [in]

Specifies the name of the argument. The command-line description used in [EXT_COMMAND](#) must specify that the type of this argument is expression.

Required [in]

Specifies if the argument is required. If *Required* is `true` and the argument was not present on the command line, **ExtInvalidArgumentException** is called. You do not need to set this parameter; if it is not set *Required* defaults to `true`.

Return value

GetArgU64 returns the value of the named expression argument.

Remarks

For an overview of argument parsing in the EngExtCpp extensions framework, see [Parsing Extension Arguments](#).

This method should only be called during the execution of an extension command provided by this class.

Requirements

Target platform

Header Engextcpp.hpp (include Engextcpp.hpp)

See also

[ExtExtension](#)
[EXT_COMMAND](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

ExtExtension.HasArg method

The **HasArg** method indicates whether a specified named argument is present in the command line used to invoke the current extension command.

Syntax

```
C++
bool HasArg(
    [in] PCSTR Name
);
```

Parameters

Name [in]

Specifies the name of the argument.

Return value

HasArg returns `true` if the argument is present; `false` if it is not present.

Remarks

This method will work for all types of named arguments. In particular, it can be used to detect the presence of a named argument of Boolean type.

If the name of the argument is a single character, the convenience method [HasCharArg](#) can be used instead.

For an overview of argument parsing in the EngExtCpp extensions framework, see [Parsing Extension Arguments](#).

This method should only be called during the execution of an extension command provided by this class.

Requirements

Target platform

Header Engextcpp.hpp (include Engextcpp.hpp)

See also

[ExtExtension](#)
[HasCharArg](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

ExtExtension.HasCharArg method

The **HasCharArg** method indicates whether a specified single-character named argument is present in the command line used to invoke the current extension command.

Syntax

```
C++
bool HasCharArg(
    [in] CHAR Name
);
```

Parameters

Name [in]

Specifies the name of the argument.

Return value

HasCharArg returns `true` if the argument is present; `false` if it is not present.

Remarks

This method will work for all types of named arguments. In particular, it can be used to detect the presence of a named argument of Boolean type.

This is a convenience method and is restricted to arguments whose name is a single character. For arguments whose names are longer than a single character, use [HasArg](#).

For an overview of argument parsing in the EngExtCpp extensions framework, see [Parsing Extension Arguments](#).

This method should only be called during the execution of an extension command provided by this class.

Requirements

Target platform

Header Engextcpp.hpp (include Engextcpp.hpp)

See also

[ExtExtension](#)

[HasArg](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

ExtExtension.SetUnnamedArg method

The **SetUnnamedArg** method sets an unnamed argument for the current extension command.

Syntax

C++

```
bool SetUnnamedArg(
    [in]        ULONG     Index,
    [in, optional] PCSTR     StrArg,
    [in]        ULONG64   NumArg,
    [in]        bool       OnlyIfUnset
);
```

Parameters

Index [in]

Specifies the index of the argument. *Index* should be between zero and the number of unnamed arguments, as specified in the command-line description used in [EXT COMMAND](#), minus one (unnamed arguments - 1).

StrArg [in, optional]

A string that specifies the value of the unnamed argument.

If the argument is of type **string**, a pointer to the first non-space character is saved as the argument. In this case, *StrArg* must not be **NULL**.

If the argument is of type **expression**, *StrArg* is evaluated using the default expression evaluator and the value returned by the default expression evaluator becomes the value of the argument. In this case, *StrArg* can be **NULL** and *NumArg* should be used instead.

If the argument is of type **Boolean**, *StrArg* is ignored and can be **NULL**.

NumArg [in]

Specifies the value of an unnamed expression argument. *NumArg* is only used if the argument is of type **expression** and *StrArg* is **NULL**.

OnlyIfUnset [in]

Specifies what happens if the argument is already set. If *OnlyIfUnset* is **true** and the argument has already been set, the argument will not be changed. If *OnlyIfUnset* is **false** and the argument has already been set, the argument will be changed.

Return value

SetUnnamedArg returns **true** if the argument was changed; **false** otherwise.

Remarks

For an overview of argument parsing in the EngExtCpp extensions framework, see [Parsing Extension Arguments](#).

This method should only be called during the execution of an extension command provided by this class.

Requirements

Target platform

Header Engextcpp.hpp (include Engextcpp.hpp)

See also

[ExtExtension](#)
[EXT_COMMAND](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

ExtExtension.SetUnnamedArgStr method

The **SetUnnamedArgStr** method sets an unnamed string argument for the current extension command.

Syntax

```
C++
bool SetUnnamedArgStr(
    [in] ULONG Index,
    [in] PCSTR Arg,
    [in] bool OnlyIfUnset
);
```

Parameters

Index [in]

Specifies the index of the argument. The command-line description used in [EXT_COMMAND](#) must specify that the type of this argument is string. *Index* should be between zero and the number of unnamed arguments - as specified in the command-line description used in EXT_COMMAND - minus one.

Arg [in]

A string that specifies the value of the unnamed argument. A pointer to the first non-space character is saved as the argument.

OnlyIfUnset [in]

Specifies what happens if the argument is already set. If *OnlyIfUnset* is true and the argument has already been set, the argument will not be changed. If *OnlyIfUnset* is false and the argument has already been set, the argument will be changed.

Return value

SetUnnamedArgStr returns true if the argument was changed; false otherwise.

Remarks

For an overview of argument parsing in the EngExtCpp extensions framework, see [Parsing Extension Arguments](#).

This method should only be called during the execution of an extension command provided by this class.

Requirements

Target platform

Header Engextcpp.hpp (include Engextcpp.hpp)

See also

[ExtExtension](#)
[EXT_COMMAND](#)

ExtExtension.SetUnnamedArgU64 method

The **SetUnnamedArgU64** method sets the value of an unnamed expression argument for the current extension command.

Syntax

```
C++
```

```
bool SetUnnamedArgU64(
    [in] ULONG     Index,
    [in] ULONG64   Arg,
    [in] bool      OnlyIfUnset
);
```

Parameters

Index [in]

Specifies the index of the argument. The command-line description used in [EXT_COMMAND](#) must specify that the type of this argument is expression. *Index* should be between zero and the number of unnamed arguments - as specified in the command-line description used in EXT_COMMAND - minus one.

Arg [in]

Specifies the value of an unnamed expression argument.

OnlyIfUnset [in]

Specifies what happens if the argument is already set. If *OnlyIfUnset* is true and the argument has already been set, the argument will not be changed. If *OnlyIfUnset* is false and the argument has already been set, the argument will be changed.

Return value

`SetUnnamedArgU64` returns `true` if the argument was changed; `false` otherwise.

Remarks

For an overview of argument parsing in the EngExtCpp extensions framework, see [Parsing Extension Arguments](#).

This method should only be called during the execution of an extension command provided by this class.

Requirements

Target platform

Header Engextcpp.hpp (include Engextcpp.hpp)

ExtExtension.SetArg method

The `SetArg` method sets a named argument for the current extension command.

Syntax

C++

```
bool SetArg(
    [in]          PCSTR     Name,
    [in, optional] PCSTR     StrArg,
    [in]          ULONG64   NumArg,
    [in]          bool      OnlyIfUnset
);
```

Parameters

Name [in]

Specifies the name of the argument.

StrArg [in, optional]

A string that specifies the value of the named argument.

If the argument is of type **string**, a pointer to the first non-space character is saved as the argument. In this case, *StrArg* must not be **NULL**.

If the argument is of type **expression**, *StrArg* is evaluated using the default expression evaluator and the value becomes the value of the argument. In this case, *StrArg* can be **NULL** and *NumArg* is used instead.

If the argument is of type **Boolean**, *StrArg* is ignored and can be **NULL**.

NumArg [in]

Specifies the value of a named expression argument. *NumArg* is only used if the type of the argument is an expression and *StrArg* is **NULL**.

OnlyIfUnset [in]

Specifies what happens if the argument is already set. If *OnlyIfUnset* is `true` and the argument has already been set, the argument will not be changed. If *OnlyIfUnset* is `false` and the argument has already been set, the argument will be changed.

Return value

SetArg returns `true` if the argument was changed; `false` otherwise.

Remarks

For an overview of argument parsing in the EngExtCpp extensions framework, see [Parsing Extension Arguments](#).

This method should only be called during the execution of an extension command provided by this class.

Requirements

Target platform

Header Engextcpp.hpp (include Engextcpp.hpp)

ExtExtension.SetArgStr method

The **SetArgStr** method sets a named string argument for the current expression command.

Syntax

```
C++
bool SetArgStr(
    [in] PCSTR Name,
    [in] PCSTR Arg,
    [in] bool OnlyIfUnset
);
```

Parameters

Name [in]

Specifies the name of the argument. The command-line description used in [EXT COMMAND](#) must specify that the type of this argument is string.

Arg [in]

A string that specifies the value of the named argument. A pointer to the first non-space character is saved as the argument. In this case, *Arg* must not be **NULL**.

OnlyIfUnset [in]

Specifies what happens if the argument is already set. If *OnlyIfUnset* is `true` and the argument has already been set, the argument will not be changed. If *OnlyIfUnset* is `false` and the argument has already been set, the argument will be changed.

Return value

SetArgStr returns `true` if the argument was changed; `false` otherwise.

Remarks

For an overview of argument parsing in the EngExtCpp extensions framework, see [Parsing Extension Arguments](#).

This method should only be called during the execution of an extension command provided by this class.

Requirements

Target platform

Header Engextcpp.hpp (include Engextcpp.hpp)

ExtExtension.SetArgU64 method

The **SetArgU64** method sets a named expression argument for the current expression command.

Syntax

```
C++
bool SetArgU64(
    [in] PCSTR  Name,
    [in] ULONG64 Arg,
    [in] bool    OnlyIfUnset
);
```

Parameters

Name [in]

Specifies the name of the argument. The command-line description used in [EXT_COMMAND](#) must specify that the type of this argument is expression.

Arg [in]

Specifies the value of the named expression argument.

OnlyIfUnset [in]

Specifies what happens if the argument is already set. If *OnlyIfUnset* is `true` and the argument has already been set, the argument will not be changed. If *OnlyIfUnset* is `false` and the argument has already been set, the argument will be changed.

Return value

SetArgU64 returns `true` if the argument was changed; `false` otherwise.

Remarks

For an overview of argument parsing in the EngExtCpp extensions framework, see [Parsing Extension Arguments](#).

This method should only be called during the execution of an extension command provided by this class.

Requirements

Target platform

Header Engextcpp.hpp (include Engextcpp.hpp)

See also

[ExtExtension](#)
[EXT_COMMAND](#)

ExtExtension.GetRawArgStr method

The **GetRawArgStr** method returns a string that represents the arguments passed to the extension command.

Syntax

```
C++
PCSTR GetRawArgStr();
```

Parameters

This method has no parameters.

Return value

`GetRawArgStr` returns a string that represents the arguments passed to the extension command. In particular, if the extension command was called from a command line, this string contains the portion of the command line that follows the extension command. The return value can be **NULL** or empty.

Remarks

For an overview of argument parsing in the EngExtCpp extensions framework, see [Parsing Extension Arguments](#).

The string returned by this method is only meaningful during the execution of the current extension command.

This method should only be called during the execution of an extension command provided by this class.

Requirements

Target platform

Header `Engextcpp.h` (include `Engextcpp.hpp`)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

ExtKnownStruct structure

The `ExtKnownStruct` structure is used to specify how a target's structure can be formatted for output.

Syntax

```
C++
struct ExtKnownStruct {
    PCSTR             TypeName;
    ExtKnownStructMethod Method;
    bool              SuppressesTypeName;
};
```

Members

TypeName

The name of the structure type.

Method

The [`ExtKnownStructMethod`](#) callback function that can be called to format an instance of the structure specified in `TypeName`.

SuppressesTypeName

A Boolean flag that specifies whether the formatted output includes the name of the structure's type. If **FALSE**, the name is included in the formatted output; otherwise, the name is not included.

Requirements

Header `Engextcpp.h` (include `Engextcpp.hpp`)

See also

[`ExtKnownStructMethod`](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

ExtExtension.ExtKnownStructMethod method

The `ExtKnownStructMethod` callback method is called by the engine to format an instance of a structure for output on a single line.

Syntax

```
C++
typedef void ExtKnownStructMethod(
    [in] PCSTR TypeName,
    [in] ULONG Flags,
    [in] ULONG64 Offset
);
```

Parameters

TypeName [in]

Specifies the name of the type of the structure pointed to by *Offset*. This is the same as the **TypeName** field of the [ExtKnownStruct](#) structure used to register this callback method.

Flags [in]

Specifies bit flags that indicate how the output should be formatted. Currently, this is set to DEBUG_KNOWN_STRUCT_GET_SINGLE_LINE_OUTPUT, which indicates that the output should be formatted for output on a single line.

Offset [in]

Specifies the location in the target's memory of the instance of the structure to be formatted for output.

Remarks

The debugger engine expects the output to be formatted for printing on a single line, hence it does not expect the formatted structure to have any line breaks.

The formatted output from this method should be placed in the buffer **m_AppendBuffer** -- a member of [ExtExtension](#).

Instances of this callback method are registered with the engine by using an instance of the [ExtKnownStruct](#) structure that is placed into the array **m_KnownStructs** (a member of [ExtExtension](#)) by the [Initialize](#) method. The [ExtKnownStruct](#) structure also specifies the name of the type of structure this method formats.

When the debugger engine calls a known structure method, it wraps the call in a **try / except** block. This protects the engine from some types of bugs in the extension code; but, because the extension calls are executed in the same thread as the engine, they can still cause it to crash.

Requirements

Target platform

Header Engextcpp.hpp (include Engextcpp.hpp)

See also

[ExtExtension](#)
[ExtKnownStruct](#)
[Initialize](#)

ExtRemoteData class

The **ExtRemoteData** class provides a wrapper around a small section of a target's memory. **ExtRemoteData** automatically retrieves the memory and provides a number of convenience methods.

The **ExtRemoteData** class includes the following constructors and methods:

[ExtRemoteData](#)
[Set\(Typed\)](#)
[Set\(Offset Bytes\)](#)
[Read](#)
[Write](#)
[GetData](#)
[GetChar](#)
[GetUchar](#)
[GetBoolean](#)

[GetStdBool](#)
[GetW32Bool](#)
[GetShort](#)
[GetUshort](#)
[GetLong](#)
[GetUlong](#)
[GetLong64](#)
[GetUlong64](#)
[GetFloat](#)
[GetDouble](#)
[GetLongPtr](#)
[GetUlongPtr](#)
[GetPtr](#)
[ReadBuffer](#)
[WriteBuffer](#)
[GetString](#)

```
class ExtRemoteData
{
public:
    PCSTR m_Name;
    ULONG64 m_Offset;
    bool m_ValidOffset;
    ULONG m_Bytes;
    ULONG64 m_Data;
    bool m_ValidData;
    bool m_Physical;
    ULONG m_SpaceFlags;
};
```

m_Name

The name given to this instance of **ExtRemoteData**. This name is used to provide meaningful error messages and is set by the constructor, [ExtRemoteData::ExtRemoteData](#).

m_Offset

The location in the target's memory (virtual or physical) of the region of memory represented by this instance of **ExtRemoteData**. It can be set by the [ExtRemoteData::ExtRemoteData](#) constructor or by the [ExtRemoteData::Set\(Typed\)](#) or [ExtRemoteData::Set\(Offset Bytes\)](#) methods.

m_ValidOffset

Indicates whether the **m_Offset** location is valid. If **m_ValidOffset** is `false`, the location is not valid and most of the methods for this object will not work. In this case, the [ExtRemoteData::Set\(Typed\)](#) or [ExtRemoteData::Set\(Offset Bytes\)](#) methods can be called to change **m_Offset** to a valid location.

m_Bytes

The size, in bytes, of the region of memory represented by this object. It can be set by the [ExtRemoteData::ExtRemoteData](#) constructor or by the [ExtRemoteData::Set\(Typed\)](#) or [ExtRemoteData::Set\(Offset Bytes\)](#) methods.

m_Data

The cached contents of the region of memory specified by this instance of **ExtRemoteData**. Setting this member is optional. If the region of memory is large, it will not be cached.

m_ValidData

Indicates whether the **m_Data** cached data is valid. If **m_ValidData** is `false`, the cached data is not valid and most of the methods for this object will not work. In this case, the [ExtRemoteData::Read](#) method can be called to refresh the cached data.

m_Physical

Indicates whether the **m_Offset** location is in the target's virtual address space or in its physical address space. If **m_Physical** is `true`, the **m_Offset** location is in the target's physical address space. If **m_Physical** is `false`, the **m_Offset** location is in the target's virtual address space.

m_SpaceFlags

The DEBUG_PHYSICAL_XXX flags used for accessing physical memory on the target. These flags are only used if **m_Physical** is `true`. For a description of these flags, see the [ReadPhysical2](#) method.

Requirements

Header Engextcpp.h (include Engextcpp.hpp)

See also

[ExtRemoteData::ExtRemoteData](#)
[ExtRemoteData::Read](#)
[ExtRemoteData::Set\(Typed\)](#)
[ExtRemoteData::Set\(Offset Bytes\)](#)

ExtRemoteData.ExtrmoteData constructor

The ExtRemoteData constructor creates a new instance of the [ExtRemoteData](#) class.

Syntax

C++
ExtRemoteData();

Parameters

This constructor has no parameters.

Remarks

If a memory region is specified, the contents of the region are read from the target and cached. The data can be retrieved using [ExtRemoteData::GetData](#) or one of the ExtRemoteTyped::GetXxx methods.

The constructor is called by the [ExtRemoteData::Set\(Typed\)](#) or [ExtRemoteData::Set\(Offset Bytes\)](#) methods and the [ExtRemoteData::GetData](#) method.

Requirements

Target platform

Header Engextcpp.h (include Engextcpp.hpp)

See also

[ExtRemoteData](#)
[ExtRemoteData::ExtRemoteData \(Offset, Bytes\)](#)
[ExtRemoteData::ExtRemoteData \(Name, Offset, Bytes\)](#)
[ExtRemoteData::GetData](#)
[ExtRemoteData::Set\(Typed\)](#)
[ExtRemoteData::Set\(Offset Bytes\)](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

ExtRemoteData.ExtrmoteData constructor

The ExtRemoteData constructor creates a new instance of the [ExtRemoteData](#) class.

Syntax

C++
ExtRemoteData(
 [in] ULONG64 Offset,
 [in] ULONG Bytes
) ;

Parameters

Offset [in]

Location of the beginning of the memory region in the target's virtual address space.

Bytes [in]

Number of bytes in the memory region.

Remarks

If a memory region is specified, the contents of the region are read from the target and cached. The data can be retrieved using [ExtRemoteData::GetData](#) or one of the ExtRemoteTyped::GetXxx methods.

The constructor is called by the [ExtRemoteData::Set\(Typed\)](#) or [ExtRemoteData::Set\(Offset Bytes\)](#) methods and the [ExtRemoteData::GetData](#) method.

Requirements

Target platform

Header Engextcpp.h (include Engextcpp.hpp)

See also

[ExtRemoteData](#)
[ExtRemoteData::ExtRemoteData](#)
[ExtRemoteData::ExtRemoteData \(Name, Offset, Bytes\)](#)
[ExtRemoteData::GetData](#)

ExtRemoteData.ExtRemoteData constructor

The **ExtRemoteData** constructor creates a new instance of the [ExtRemoteData](#) class.

Syntax

```
C++
ExtRemoteData(
    [in] PCSTR  Name,
    [in] ULONG64 Offset,
    [in] ULONG   Bytes
);
```

Parameters

Name [in]

Name of the memory region. *Name* can be used to help identify the region and will be inserted into any error messages generated by the new object.

Offset [in]

Location of the beginning of the memory region in the target's virtual address space.

Bytes [in]

Number of bytes in the memory region.

Remarks

If a memory region is specified, the contents of the region are read from the target and cached. The data can be retrieved using [ExtRemoteData::GetData](#) or one of the ExtRemoteTyped::GetXxx methods.

The constructor is called by the [ExtRemoteData::Set\(Typed\)](#) or [ExtRemoteData::Set\(Offset Bytes\)](#) methods and the [ExtRemoteData::GetData](#) method.

Requirements

Target platform

Header Engextcpp.h (include Engextcpp.hpp)

See also

[ExtRemoteData](#)
[ExtRemoteData::ExtRemoteData](#)
[ExtRemoteData::ExtRemoteData \(Name, Offset, Bytes\)](#)
[ExtRemoteData::GetData](#)
[ExtRemoteData::Set\(Typed\)](#)
[ExtRemoteData::Set\(Offset Bytes\)](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

ExtRemoteData::Set method

The **Set** method sets the region of the target's memory represented by the [ExtRemoteData](#) object.

Syntax

```
C++
void Set(
    [in] ULONG64 Offset,
    [in] ULONG    Bytes
);
```

Parameters

Offset [in]

Location of the beginning of the memory region in the target's virtual address space.

Bytes [in]

Number of bytes in the memory region.

Return value

This method does not return a value.

Remarks

The **Set** method will read the contents of the specified region of memory and cache the data. The data can be retrieved using [ExtRemoteData::GetData](#) or one of the ExtRemoteTyped::GetXxx methods.

Requirements

Target platform

Header Engextcpp.h (include Engextcpp.hpp)

See also

[ExtRemoteData](#)
[ExtRemoteData::Set \(Typed\)](#)
[ExtRemoteData::ExtRemoteData](#)
[ExtRemoteData::GetData](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

ExtRemoteData::Set method

The **Set** method sets the region of the target's memory represented by the [ExtRemoteData](#) object.

Syntax

```
C++
void Set(
    [in] const DEBUG_TYPED_DATA *Typed
);
```

Parameters

Typed [in]

Specifies the region of memory by using a [DEBUG_TYPED_DATA](#) structure.

Return value

This method does not return a value.

Remarks

The **Set** method will read the contents of the specified region of memory and cache the data. The data can be retrieved using [ExtRemoteData::GetData](#) or one of the ExtRemoteTyped::GetXxx methods.

Requirements

Target platform

Header Engextcpp.h (include Engextcpp.hpp)

See also

[ExtRemoteData](#)
[ExtRemoteData::Set \(Offset, Bytes\)](#)
[ExtRemoteData::ExtRemoteData](#)
[ExtRemoteData::GetData](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

ExtRemoteData.Read method

The **Read** method reads the contents of the target's memory, represented by the [ExtRemoteData](#) object, and then caches the data.

Syntax

C++
void Read();

Parameters

This method has no parameters.

Return value

This method does not return a value.

Remarks

When the region of memory is specified either by the [ExtRemoteData::ExtRemoteData](#) constructor or by the [ExtRemoteData::Set\(Typed\)](#) or [ExtRemoteData::Set\(Offset Bytes\)](#) methods, the contents are automatically read from the target and cached. This method only needs to be called if the memory on the target might have changed.

The data can be retrieved using [ExtRemoteData::GetData](#) or one of the typed "get" methods.

Requirements

Target platform

Header Engextcpp.h (include Engextcpp.hpp)

See also

[ExtRemoteData](#)
[ExtRemoteData::ExtRemoteData](#)
[ExtRemoteData::GetData](#)
[ExtRemoteData::Set\(Typed\)](#)
[ExtRemoteData::Set\(Offset Bytes\)](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

ExtRemoteData::Write method

The **Write** method writes the data cached by the [ExtRemoteData](#) object to the region of memory on the target, represented by this object.

Syntax

```
C++  
void Write();
```

Parameters

This method has no parameters.

Return value

This method does not return a value.

Remarks

This method can be used to reset the region of memory on the target to the currently cached value that was previously read from the target.

It is also possible to directly set the value cached by the [ExtRemoteData](#) object, for example:

```
ExtRemoteData ext_remote_data = new ExtRemoteData(address, sizeof(USHORT));  
ext_remote_data.m_Data = (ULONG64) my_ushort;  
ext_remote_data.Write();
```

Requirements

Target platform

Header Engextcpp.h (include Engextcpp.hpp)

See also

[ExtRemoteData](#)
[ExtRemoteData::Read](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

ExtRemoteData::GetData method

The **GetData** method returns the contents of the target's memory, represented by the [ExtRemoteData](#) object.

Syntax

```
C++  
ULONG64 GetData(  
    [in] ULONG Request  
>;
```

Parameters

Request [in]

Number of bytes requested. This must be the same as the size of the memory specified by the [ExtRemoteData::ExtRemoteData](#) constructor or the [ExtRemoteData::Set\(Typed\)](#) or [ExtRemoteData::Set\(Offset Bytes\)](#) methods. If it is not the same, [ExtRemoteException](#) is thrown.

Return value

GetData returns the cached contents of the target's memory, represented by the [ExtRemoteData](#) object.

Remarks

The contents of the region of memory represented by an [ExtRemoteData](#) object are only cached if the size of the region is less than 8 bytes. If the size of the region is greater than 8 bytes, the **GetData** method does not return a meaningful value.

A number of convenience methods are available for various primitive types. These methods will automatically provide the size of the type and cast the return value to that type. These methods are listed in the See Also section.

Requirements

Target platform

Header Engextcpp.h (include Engextcpp.hpp)

See also

ExtRemoteData.GetChar method

The GetChar method returns a CHAR version of the [ExtRemoteData](#) object, which represents the contents of the target's memory.

Syntax

C++
CHAR GetChar();

Parameters

This method has no parameters.

Return value

GetChar returns the CHAR version of the [ExtRemoteData](#) object.

Remarks

The size of the memory represented by the [ExtRemoteData](#) object must be `sizeof(CHAR)`.

Requirements

Target platform

Header Engextcpp.h (include Engextcpp.hpp)

See also

[ExtRemoteData](#)
[ExtRemoteData::GetData](#)
[ExtRemoteData::GetUchar](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

ExtRemoteData.GetUchar method

The **GetUChar** method returns a UCHAR version of the [ExtRemoteData](#) object, which represents the contents of the target's memory.

Syntax

C++
UCHAR GetUchar();

Parameters

This method has no parameters.

Return value

GetUChar returns the UCHAR version of the [ExtRemoteData](#) object.

Remarks

The size of the memory represented by the [ExtRemoteData](#) object must be `sizeof(UCHAR)`.

Requirements

Target platform

Header Engextcpp.h (include Engextcpp.hpp)

See also

[ExtRemoteData](#)
[ExtRemoteData::GetChar](#)
[ExtRemoteData::GetData](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

ExtRemoteData.GetBoolean method

The **GetBoolean** method returns a Boolean version of the [ExtRemoteData](#) object, which represents the contents of the target's memory.

Syntax

C++
BOOLEAN GetBoolean();

Parameters

This method has no parameters.

Return value

GetBoolean returns the BOOLEAN version of the [ExtRemoteData](#) object.

Remarks

The size of the memory represented by the [ExtRemoteData](#) object must be `sizeof(BOOLEAN)`.

Note There are several different types that can be used to represent a Boolean value. BOOLEAN is one of these types. For the C++ **bool** type, use [ExtRemoteData::GetStdBool](#). For the BOOL type, use [ExtRemoteData::GetW32Bool](#).

Requirements

Target platform

Header Engextcpp.h (include Engextcpp.hpp)

See also

[ExtRemoteData](#)
[ExtRemoteData::GetData](#)
[ExtRemoteData::GetStdBool](#)
[ExtRemoteData::GetW32Bool](#)

ExtRemoteData.GetStdBool method

The **GetStdBool** method returns a **bool** version of the [ExtRemoteData](#) object, which represents the contents of the target's memory.

Syntax

```
C++  
bool GetStdBool();
```

Parameters

This method has no parameters.

Return value

The **bool** version of the [ExtRemoteData](#) object.

Remarks

The size of the memory represented by the [ExtRemoteData](#) object must be `sizeof(bool)`.

Note There are several different types that can be used to represent a Boolean value. **bool** is one of these types. For the BOOLEAN type, use [ExtRemoteData::GetBoolean](#). For the BOOL type, use [ExtRemoteData::GetW32Bool](#).

Requirements

Target platform

Header Engextcpp.h (include Engextcpp.hpp)

See also

[ExtRemoteData](#)
[ExtRemoteData::GetBoolean](#)
[ExtRemoteData::GetData](#)
[ExtRemoteData::GetW32Bool](#)

[Send comments about this topic to Microsoft](#)

© 2016 Microsoft. All rights reserved.

ExtRemoteData.GetW32Bool method

The **GetW32Bool** method returns a **BOOL** version of the [ExtRemoteData](#) object, which represents the contents of the target's memory.

Syntax

```
C++  
BOOL GetW32Bool();
```

Parameters

This method has no parameters.

Return value

GetW32Bool returns the **BOOL** version of the [ExtRemoteData](#) object.

Remarks

The size of the memory represented by the [ExtRemoteData](#) object must be `sizeof(BOOL)`.

Note There are several different types that can be used to represent a Boolean value. BOOL is one of these types. For the C++ `bool` type, use [ExtRemoteData::GetStdBool](#). For the BOOLEAN type, use [ExtRemoteData::GetBoolean](#).

Requirements

Target platform

Header Engextcpp.h (include Engextcpp.hpp)

See also

[ExtRemoteData](#)
[ExtRemoteData::GetBoolean](#)
[ExtRemoteData::GetData](#)
[ExtRemoteData::GetStdBool](#)

ExtRemoteData.GetShort method

The **GetShort** method returns a SHORT version of the [ExtRemoteData](#) object, which represents the contents of the target's memory.

Syntax

```
C++
SHORT GetShort();
```

Parameters

This method has no parameters.

Return value

GetShort returns the SHORT version of the [ExtRemoteData](#) object.

Remarks

The size of the memory represented by the [ExtRemoteData](#) object must be `sizeof(SHORT)`.

Requirements

Target platform

Header Engextcpp.h (include Engextcpp.hpp)

ExtRemoteData.GetUshort method

The **GetUshort** method returns a USHORT version of the [ExtRemoteData](#) object, which represents the contents of the target's memory.

Syntax

```
C++
```

```
USHORT GetUshort();
```

Parameters

This method has no parameters.

Return value

`GetUshort` returns the USHORT version of the [ExtRemoteData](#) object.

Remarks

The size of the memory represented by the [ExtRemoteData](#) object must be `sizeof(USHORT)`.

Requirements

Target platform

Header Engextcpp.h (include Engextcpp.hpp)

ExtRemoteData.GetLong method

The `GetLong` method returns a LONG version of the [ExtRemoteData](#) object, which represents the contents of the target's memory.

Syntax

```
C++  
LONG GetLong();
```

Parameters

This method has no parameters.

Return value

`GetLong` returns the LONG version of the [ExtRemoteData](#) object.

Remarks

The size of the memory represented by this [ExtRemoteData](#) object must be `sizeof(LONG)`.

Requirements

Target platform

Header Engextcpp.h (include Engextcpp.hpp)

See also

[ExtRemoteData](#)
[ExtRemoteData::GetData](#)

ExtRemoteData.GetUlong method

The `GetUlong` method returns a `ULONG` version of the [ExtRemoteData](#) object, which represents the contents of the target's memory.

Syntax

```
C++  
ULONG GetUlong();
```

Parameters

This method has no parameters.

Return value

`GetUlong` returns the `ULONG` version of the [ExtRemoteData](#) object.

Remarks

The size of the memory represented by the [ExtRemoteData](#) object must be `sizeof(ULONG)`.

Requirements

Target platform

Header Engextcpp.h (include Engextcpp.hpp)

See also

[ExtRemoteData](#)
[ExtRemoteData::GetData](#)

ExtRemoteData.GetLong64 method

The `GetLong64` method returns a `LONG64` version of the [ExtRemoteData](#) object, which represents the contents of the target's memory.

Syntax

```
C++  
LONG64 GetLong64();
```

Parameters

This method has no parameters.

Return value

`GetLong64` returns the `LONG64` version of the [ExtRemoteData](#) object.

Remarks

The size of the memory represented by the [ExtRemoteData](#) object must be `sizeof(LONG64)`.

Requirements

Target platform

Header Engextcpp.h (include Engextcpp.hpp)

See also

[ExtRemoteData](#)
[ExtRemoteData::GetData](#)

ExtRemoteData.GetUlong64 method

The **GetUlong64** method returns a ULONG64 version of the [ExtRemoteData](#) object, which represents the contents of the target's memory.

Syntax

```
C++  
ULONG64 GetUlong64();
```

Parameters

This method has no parameters.

Return value

GetUlong64 returns the ULONG64 version of the [ExtRemoteData](#) object.

Remarks

The size of the memory represented by the [ExtRemoteData](#) object must be `sizeof(ULONG64)`.

Requirements

Target platform

Header Engextcpp.h (include Engextcpp.hpp)

ExtRemoteData.GetFloat method

The **GetFloat** method returns a **float** version of the [ExtRemoteData](#) object, which represents the contents of the target's memory.

Syntax

```
C++  
float GetFloat();
```

Parameters

This method has no parameters.

Return value

GetFloat returns the **float** version of the [ExtRemoteData](#) object.

Remarks

The size of the memory represented by the [ExtRemoteData](#) object must be `sizeof(float)`.

Requirements

Target platform

Header Engextcpp.h (include Engextcpp.hpp)

See also

[ExtRemoteData](#)
[ExtRemoteData::GetData](#)
[ExtRemoteData::GetDouble](#)

ExtRemoteData.GetDouble method

The **GetDouble** method returns a **double** version of the [ExtRemoteData](#) object, which represents the contents of the target's memory.

Syntax

```
C++
double GetDouble();
```

Parameters

This method has no parameters.

Return value

GetDouble returns the **double** version of the [ExtRemoteData](#) object.

Remarks

The size of the memory represented by the [ExtRemoteData](#) object must be `sizeof(double)`.

Requirements

Target platform

Header Engextcpp.h (include Engextcpp.hpp)

See also

[ExtRemoteData](#)
[ExtRemoteData::GetData](#)
[ExtRemoteData::GetFloat](#)

ExtRemoteData.GetLongPtr method

The **GetLongPtr** method returns a signed integer version (extended to LONG64) of the [ExtRemoteData](#) object, which represents the contents of the target's memory. The size of the unsigned integer from the target is the same size as a pointer on the target.

Syntax

```
C++
LONG64 GetLongPtr();
```

Parameters

This method has no parameters.

Return value

GetLongPtr returns a signed integer version of the [ExtRemoteData](#) object, extended to LONG64.

Remarks

The size of the memory represented by the [ExtRemoteData](#) object must be the same as the size of a pointer on the target, `ExtExtension::m_PtrSize`.

Requirements

Target platform

Header Engextcpp.h (include Engextcpp.hpp)
